IGC 2024 Scientific Program

Plenary

T1. Sedimentary Geology

S1+S3. Continental Margin Sedimentology and Environment Change

- Oral 17
- Poster 43

S2: Black Shale Science and Economy

- Oral 76
- Poster 104

S4: Impact of volcanism on sedimentary systems

- Oral 125
- Poster 132

S5: Diagenesis and sedimentary environment

- Oral 135
- Poster 151

S6: Paleoenvironments of the early Paleozoic world

- Oral 177
- Poster 192

S7: General Topics in Sedimentary Geology

- Oral 196
- Poster 219

T2. Quaternary Geology

S1 Mapping the Quaternary geology: from detailed regional mapping campaigns to small- scale compilations

- Oral 271
- Poster 284

S2: Present Earth Surface Processes and Long-term Environmental Changes in East Eurasia

- Oral 288
- Poster 307

S3: Current and future directions in Quaternary chronostratigraphy

- Oral 315
- Poster 325

S4: A global perspective on the Neogene–Quaternary (Pliocene–Pleistocene) boundary

- Oral 329
- Poster 336

S5+S8: Geological Sea-level Proxies of Marine Isotopic Stage (MIS) 5 in the Asian Shorelines

- Oral 341
- Poster 353

S6: Youngest Quaternary (Meghalayan Stage) Speleothems and global Paleoclimate events

- Oral 363
- Poster 372

S7: New Advances in Paleolithic Sites and Early Human Settlement

- Oral 380

T3 Earth History and Stratigraphy

S1_Evolution of habitability of the early Earth Oral 409

- Oral 385
- Poster 397

S2: The Neoproterozoic-Lower Paleozoic stratigraphy, sedimentation, paleoclimate, chemostratigraphy and correlation of the Southwest and East Gondwana

- Oral 405
- Poster 412

S3: Evolution of Earth surface system from the Carboniferous to the Triassic

- Oral 423

S4+S5: The end-Permian mass extinction - state of knowledge and future advances

- Oral 442
- Poster 454

S6: Paleogeography of the Tethys Oceans

- Oral 459
- Poster 482

S7: Cretaceous Earth Dynamics and Climate in Asia (Joint Session of IGCP 679)

- Oral 502
- Poster 514

S8: General Topics

- Oral 522
- Poster 541

T4 Tectonophysics

S1: Eastern Asia tectonic evolution under the multi-plate convergent geodynamics during late Mesozoic

- Oral 574
- Poster 582

S2+S4: Intraplate tectonics and seismicity

- Oral 590
- Poster 602

S3: Deformation processes and texture analysis

- Oral 607
- Poster 620

S5: Structure, magmatism and evolution process of oceanic and marginal seas' lithosphere

- Oral 631
- Poster 643

S6_Active Tectonics and Earthquake Geology

- Oral 661
- Poster 670

S7_Tectonic evolution of modern and ancient orogens in 4D

- Oral 684
- Poster 698

S8: Subduction-related sedimentary basin evolution and lithospheric dynamics

- Oral 704
- Poster 711

S9: Deciphering complex plate tectonics from the ocean floor

- Oral 716
- Poster 720

S10+S13: Towards better understanding the origin of intraplate earthquakes in East Asia

- Oral 721
- Poster 727

S11: Geology and Tectonics of the Western Pacific Marginal Seas

- Oral 738
- Poster 754

S12: Deep Earth Exploration and Earth CT

- Oral 761
- Poster 776

T5 Planetary Sciences

S2+S1: Geological Exploration of Lunar and Martian Terrains

- Oral 785
- Poster 793

S3+S4: The interiors of the Earth, solar system planets, and exoplanets

- Oral 796
- Poster 805

S5+S6: Meteorites: Probing the Origins and Evolution of our Solar System

- Oral 809
- Poster 815

S7+S8: Planetary Habitability: From Extremophiles to Potential Life

- Oral 819
- Poster 826

S9+S10: Comparative Planetary Geology Studies

- Oral 828

S12+S11+S13+S14: Lunar Science and Exploration

- Oral 837
- Poster 841

T6 metamorphism

S1: Application of thermodynamic modelling in understanding the process of metamorphism

- Oral 856
- Poster 866

S2: Subduction zone fluids: mineralogical and geochemical effects and geodynamic consequences

- Oral 872
- Poster 891

S3: General Topics Oral 967

- Oral 921
- Poster 932

T7 Volcanology

S1: Large Igneous Provinces in Space and Time

- Oral 942
- Poster 960

S2+S5: Cretaceous Volcanism: Global Distribution Bearing on Tectonics of Continents and Oceanic Regions, K-T Boundary and Major Extinction

- Oral 971
- Poster 979

S3: Volcano Geology: role of field work on modern Volcanology

- Oral 997
- Poster 1003

S4: Volcanism on the Korean Peninsula

- Oral 1007
- Poster 1014

T8 Petrology

S1: Architecture and Thermal Structure of Translithospheric Magmatic Systems
- Oral 1021
- Poster 1031

S2: Granitoids and their enclaves
- Oral 1036
- Poster 1054

S3: Crust-Mantle interactions through time and the role of fluids
- Oral 1073
- Poster 1091

S4: Oceanic lithosphere evolution: crust-mantle geodynamics to melt processes and reservoirs
- Oral 1097
- Poster 1102

S5: Ophiolite: A window to the oceanic mantle across the geological time
- Oral 1104
- Poster 1119

S6: The petrological and related tectonic interpretations of Northeast Asia.
- Oral 1140
- Poster 1169

S7: General Topics
- Oral 1178
- Poster 1206

T9-Structural Geology

S1: 3D geological mapping: international status, barriers, and perspectives of geomodelling
- Oral 1224
- Poster 1241

S2_Shear Zone Tectonics
- Oral 1242
- Poster 1251

S3: Modern techniques for understanding faults and their effects on fault activity and fluid flow
- Oral 1262
- Poster 1273

S4: Fault damage zones in active and fossil faults
- Oral 1283
- Poster 1297

S5: Active faulting behavior, earthquake hazards zonation and urban prevention strategies: Field observation, data process and scene simulation
- Oral 1302
- Poster 1318

S7: Himalaya, Karakoram and Tibet: the geology and tectonics of a giant orogen
- Oral 1329
- Poster 1347

S8: From microscale to macroscale: multidimensional exploration in structural geology and tectonics
- Oral 1360
- Poster 1375

S9: Fault zones and fluid interactions, key structures for energy transition
- Oral 1387
- Poster 1403

S10: Geological architecture and active tectonics of Central and Eastern Himalayas
- Oral 1414
- Poster 1421

S11+S6: General Topics
- Oral 1423
- Poster 1441

T10 Geomorphology

S1+S6: Understanding Cover and its links with basement geology through Earth's history
- Oral 1457
- Poster 1463

S2: 'Landslides and climate changes' (IAG Co-Sponsored Session)
- Oral 1468

S4: Exploring high-resolution spatial and temporal data to resolve geologic and geomorphic processes
- Oral 1481
- Poster 1495

S5+S3: The role of climate, tectonics and surface processes in landscape evolution of the Himalayan-Tibetan orogen
- Oral 1505
- Poster 1522

T11-Paleontology and Paleoanthropology

S1_Cambrian Explosion and Co-evolution of environment Oral 1619
- Oral 1527
- Poster 1568

S2_The Evolution of Land Plants and Plant–Environment Interactions during Geological Time
- Oral 1576
- Poster 1591

S3_Ostracoda in Geology, the 5th Asian Ostracod Meeting (AOM)
- Oral 1600
- Poster 1614

S4: Paleocene-Eocene larger benthic Foraminifera, paleobiogeography and collision of Indian and Asian Plates
- Oral 1631
- Poster 1639

S5: Functional morphology and biomechanics in invertebrates: new ecological and evolutionary perspectives
- Oral 1640

S6: Early Palaeozoic faunas and palaeobiogeography of NE peri-Gondwana
- Oral 1647
- Poster 1672

S7: Recent advances in palaeontology from Asia (APA open session)
- Oral 1678
- Poster 1711

S8+S9: The floral diversity variation and palaeoenvironmental background across the terrestrial Triassic and Jurassic transition
- Oral 1715
- Poster 1721

S10: General contributions to Paleontology and Paleoanthropology
- Oral 1724
- Poster 1738

T12_Resource Geology and Economic Geology

S1_Resource Prospecting of Critical Metals and Economic Processing
- Oral 1754
- Poster 1766

S2_Exploration Targeting of Critical Metals
- Oral 1772
- Poster 1791

S3_Granitic Pegmatite-Hosted Critical Mineral Deposits
- Oral 1811
- Poster 1820

S4_Co-Ni mineralization mechanism related to sedimentary, metamorphic, magmatic and weathering processes
- Oral 1829
- Poster 1838

S5: Mining for a Better Energy Future: Sustaining the Supply of Critical Raw Materials
- Oral 1849
- Poster 1856

S7: Petroleum Enrichment and the Tethys Geodynamic System
- Oral 1861
- Poster 1888

S8: Metamorphic fluid mineralization and Ore Remobilization
- Oral 1928
- Poster 1952

S9_Promoting best practice in utilization of Geo resources (including Mineral, Water and Energy)
- Oral 1963
- Poster 1969

S10: Geo-Resources in Sustainable (Economic) Development
- Oral 1971
- Poster 1980

S11: Marine Mineral deposits, science, resources, technology, and environmental challenges, a look to the future
- Oral 1981
- Poster 2000

S12+S16: Novel approaches to modelling a sustainable and integrated minerals value chain
- Oral 2016
- Poster 2024

S13: Geometallurgy
- Oral 2030
- Poster 2036

S14_Ore-forming Magmatic Hydrothermal Systems: analysis of source to sink in deposit genesis
- Oral 2042
- Poster 2073

S15_Lithocaps and high sulfidation epithermal deposits
- Oral 2093

S17: Rare criticals metal geochemistry and mineral deposits
- Oral 2101
- Poster 2113

S18: Hydrodynamic studies of mineralization
- Oral 2126
- Poster 2134

S19: Mineralogy and Ore deposits in Alp-Himalaya belt
- Oral 2135

S20: Metallogeny and Geodynamics of East and SE Asia
- Oral 2142
- Poster 2162

S21: Uranium, thorium and related atomic energy minerals resources
- Oral 2170
- Poster 2186

S22: Iron Mineral System
- Oral 2197

S23: Navigating the Path to the Green Transition: Balancing Resource Extraction and Environmental Stewardship
- Oral 2204
- Poster 2213

S24+S6: HTHP geofluid-rock interactions, mass circulation and deep hydrocarbons in sedimentary basins
- Oral 2215
- Poster 2228

S25: Advances and Innovations in Uranium Exploration and Resource Evaluation. (A special session in memory of the late Dr. K. Kyser)
- Oral 2246

S26: General Topics
- Oral 2252
- Poster 2265

T13-Mineralogy

S2: Gemstone and Geological Formation
- Oral 2287
- Poster 2304

S3+S1+S5: Geochemistry, Isotopic Characteristics, and Geochronology of Gem deposits
- Oral 2312
- Poster 2319

S4: Environmental Mineralogy: From Understanding To Applicationr
- Oral 2331
- Poster 2347

S6: Silicate melts, magmas, and non-crystalline earth materials in Earth and Planetary Surfaces and Interior
- Oral 2357
- Poster 2368

S7: Gem materials
- Oral 2376
- Poster 2394

S8: General Topics
- Oral 2410
- Poster 2415

T14-Low Temperature Geohemistry

S1_Challenges and Opportunities of Global-Scale Geochemical Mapping (4th Arthur Darnley Symposium)
- Oral 2444
- Poster 2467

S2_Application of metal isotope fractionation in low temperature geochemistry
- Oral 2474
- Poster 2487

S3: Geochemical Signatures of Earth Surface Processes
- Oral 2491
- Poster 2498

S4+S5: New geochemical application of Rare Earth Elements and their Isotopes in low temperature geochemical environment
- Oral 2503
- Poster 2511

T15_Paleoclimate and Paleceanography

S1+S2: Paleoclimate and paleoceanography in the Ross Sea, Antarctica
- Oral 2514
- Poster 2520

S3: Recent developments in paleoclimatology
- Oral 2523
- Poster 2535

S4: General Topics
- Oral 2541
- Poster 2551

T16_Coastal, Marine and Lacustrine Geosciences

S1_Geohazard assessment from submarine landslides: a multi-stage approach
- Oral 2561
- Poster 2570

S2+S3: Coastal Environment Risk and its Influence on the Economic Development of a Country
- Oral 2571
- Poster 2577

S4: Beach sedimentary processes and mechanism
- Oral 2581
- Poster 2585

S5: Records of Climate and environmental change from lacustrine sediment
- Oral 2590
- Poster 2601

S6+S8: Sedimentation, sediment transport, and morphodynamics on the coastal system
- Oral 2612
- Poster 2620

S7: EMODNET-Geology's new standards revealing Earth's seabed geology
- Oral 2638
- Poster 2653

T17_Geoscience in Alpine and Polar Regions

S1+S4_Status of Himalayan Glaciers under the current climate change scenario
- Oral 2661
- Poster 2668

S2: Arctic evolution and climate changes during the Cenozoic
- Oral 2676
- Poster 2683

S3: Ice core science for alpine and polar ice cores
- Oral 2686
- Poster 2691

T18_Groundwater and Hydrogeology

S1: Microplastics and nanoplastics in soil and groundwater
- Oral 2694
- Poster 2699

S2: Groundwater Development for achieving food security and improving rural health in low- income countries
- Oral 2701
- Poster 2709

S3: Integrated use of groundwater and surface water resources keeping up with extreme droughts periods
- Oral 2723
- Poster 2729

S4: Eco-hydrological Process and its Effects in Karst Environment
- Oral 2731

S5: KRC Special session: Drought vulnerability of groundwater aquifer under climate crisis environment in S. Korea
- Oral 2743

S6: Groundwater and surface water interactions
- Oral 2749
- Poster 2761

S7: General Topics
- Oral 2771
- Poster 2782

T19 Geobiology

S1: Microbial carbonates through space and time
- Oral 2814

S2: Assessing the interplay of environmental and evolutionary controls in animal-substrate interactions through time
- Oral 2832
- Poster 2842

S3: Mid-Phanerozoic mass extinctions, recovery, extreme environmental events and integrated stratigraphic correlations
- Oral 2845
- Poster 2867

S4: General Topics
- Oral 2868
- Poster 2875

T20. Biogeochemical cycles

S3+S2. Local scale fluxes of carbon dioxide in urban environment: Sectorial emission and sequestration challenges
- Oral 2876
- Poster 2883

S4+S1. General Topics
- Oral 2884
- Poster 2889

T21. Environmental Geosciences

S1. Geoscience knowledge in Environment and Environmental Ecosystem
- Oral 2894
- Poster 2901

S3+S2. Anthropogenic contaminants in the environment
- Oral 2906
- Poster 2923

S4+S5: Emerging environmental pollutants, hazards, and energy resources and their associated human-natural system risks: Oral and postal presentation
- Oral 2949
- Poster 2957

T22. GIS and Remote Sensing

S1+S11. Remote Sensing of Global Resources with the New and Forthcoming Generation of Satellite Sensors
- Oral 2985
- Poster 2997

S2. Geoscience information, geological mapping and modelling
- Oral 3002
- Poster 3021

S5+S3+S6. Advances in GIS and remote sensing approach for geological hazards management
- Oral 3040
- Poster 3051

S7. Mapping the Way Forward: Advances in Applied Geoinformatics for Mineral Exploration
- Oral 3071
- Poster 3081

S8. Advances in AI and remote sensing approach for tidal flat monitoring
- Oral 3086
- Poster 3091

S9. Artificial Intelligence Methods Applied to Geological hazard using Remote Sensing and GIS
- Oral 3093

S10. Geoscience Information in the 2020s
- Oral 3097
- Poster 3105

T23. Seismology

S2+S1. Statistical Seismology and Episodic Events
- Oral 3112
- Poster 3116

S3. East Asia Earthquakes, Seismic Structure and Tectonics
- Oral 3117
- Poster 3133

S5. The 2023 M7.8 and M7.5 Kahramanmaraş, Turkey, Earthquake Sequence
- Oral 3146
- Poster 3163

S6. Investigating subsurface structures with dense seismic array: Theories and applications
- Oral 3170
- Poster 3178

S7. Site survey and seismic safety for nuclear installations (Sponsor Special Session)
- Oral 3191
- Poster 3198

S8+S4. General Topics
- Oral 3207
- Poster 3214

T24. Geophysics

S1. Fault detection and paleoseismology with near-surface geophysics
- Oral 3236
- Poster 3242

S2. Coupling of deep Earth and surface processes
- Oral 3246
- Poster 3257

S3. New Insights into the evolution of Deccan Volcanic Province and its seismic scenario
- Oral 3262
- Poster 3278

S6+S4+S5. Trending Machine Learning Applications in Oil and Gas Industry
- Oral 3284
- Poster 3290

S7. General Topics
- Oral 3292
- Poster 3299

T25. Geotechnology and Geophysical Exploration

S1. Advances in Geophysical Exploration Techniques for Resource Characterization
- Oral 3313
- Poster 3324

S2+S3. Geotechnology and its Applications in Geological Hazard Assessment and Monitoring
- Oral 3333
- Poster 3342

T26. Geoscience Education

S1. Geology Degrees Across the World – How are the Next Generation of Geologists Being Educated for the Geosciences of Tomorrow
- Oral 3348
- Poster 3355

S2. Exploring Geoscience Across the Globe: Special Session in Memory of Chris King
- Oral 3357
- Poster 3361

S4. International perspectives for natural disaster education
- Oral 3364

S5. Geoscience Education and Outreach for All: Techniques and Trends for Engaging Non- Specialist Learners
- Oral 3375
- Poster 3389

S6. Geoscience Education and Awareness
- Oral 3402
- Poster 3408

S7. Mitigating multi-hazard risks: perception, awareness and educational perspectives to cultivate a risk culture and strengthen disaster resilience in vulnerable communities
- Oral 3412

S8. International Perspectives on Earth Science Education
- Oral 3418
- Poster 3430

S9. General Topics
- Oral 3433
- Poster 3438

T27. Geoheritage, Geopark, and Geotourism

S1+S2. Heritage Stone: safeguarding the cultural and social legacy of rocks
- Oral 3448
- Poster 3464

S3. Geosites and Georoutes in the History of Geological Sciences
- Oral 3466
- Poster 3475

S4. Geoconservation and Geoheritage: geodiversity underpinning natural systems
- Oral 3478
- Poster 3506

S6. Geoscience in Geoheritage, Geoparks and Geotourism
- Oral 3521
- Poster 3539

S8. The Second 100 IUGS Geological Heritage Sites

- Oral 3552
- Poster 3581

S9. Global Geopark Network (GGN)/Geoparks and Society

- Oral 3583
- Poster 3593

S10. TRANSNATIONAL UNESCO GLOBAL GEOPARKS: The need and historical value of designating a transnational UNESCO Geopark in East Asia - focusing on Mount Baekdu and the Hantan River on the Korean Peninsula

- Oral 3606
- Poster 3613

S11. General Topics

- Oral 3615
- Poster 3619

T28. Forensic Geology and Medical Geology

S2+S1+S3. Medical Geology in Honour of Professor Olle Selinus (Special Session)

- Oral 3625
- Poster 3661

T29. Engineering Geology and Geomechanics

S2+S1. General Topics

- Oral 3674
- Poster 3689

T30. Urban Geology S2+S1. General Topics Oral 3934

- Oral 3708
- Poster 3717

T31. Geohazards

S1+S4. Surface faulting and near-fault earthquake hazard

- Oral 3718
- Poster 3727

S2. Outreach tools as a way to increase preparedness for geological hazards

- Oral 3743
- Poster 3750

S3. Geohazards: A global phenomenon and their Reduction Strategies

- Oral 3753
- Poster 3768

S5. Our Tasks on Global Submarine Geohazard issues to our future earth

- Oral 3770
- Poster 3783

S6+S7. Advances in Modeling and Simulation of Geological Disaster Problems

- Oral 3792
- Poster 3801

T32. Mitigation and Adaptation in Climate Crisis

S1+S2. Geoscience Contributions to Climate Change Mitigation Strategies

- Oral 3817
- Poster 3826

S3+S4. Offshore Monitoring Technology and its Application for CO2 Storage

- Oral 3835
- Poster 3843

T33. Big Data and Artificial Intelligence (AI) in Geoscience

S1+S2. Application of AI algorithms in natural hazards modelling Oral 4080

- Oral 3849
- Poster 3853

S3. Prediction of reservoir response using machine learning and data integration

- Oral 3860
- Poster 3864

S4. Data-driven or AI-driven Discovery in Geosciences

- Oral 3866
- Poster 3882

S6. Big Data and Artificial Intelligence (AI) in Geomodeling

- Oral 3908
- Poster 3917

S7+S5. General Topics

- Oral 3931
- Poster 3934

T34. Energy and Carbon Neutrality

S1. Geothermal energy, geoenergy, geopower, geoheat, earth energy

- Oral 3946
- Poster 3959

S2. Offshore renewable energy systems and submarine geohazards

- Oral 3964
- Poster 3970

S3. Assessment of innovation necessary for sustainable use of geothermal resources

- Oral 3971

S4+S6+S7. Critical Minerals Governance for Carbon Neutrality

- Oral 3982
- Poster 3986

S5. Unconventional Oil and Gas Resources & CO2 Geological Sequestration

- Oral 4000
- Poster 4029

T35. Geoscience and Policy

S2+S4+T22 S4. Geothermal energy, geoenergy, geopower, geoheat, earth energy

- Oral 4073
- Poster 4102

S3+S1+S6. Responsible Mining of Critical Minerals and the Importance of Environmental Justice

- Oral 4111
- Poster 4124

S5. Empowering women in geoscience for gender equality

- Oral 4127
- Poster 4132

T36. Management of Radioactive Resources and Waste

S1+S5. Advances in natural and engineering barriers for underground nuclear waste repositories
- Oral 4134
- Poster 4137

S2. Investigation and evaluation techniques related with nuclear power plants and waste disposal sites
- Oral 4150
- Poster 4159

S3. Transport of radionuclides in deep geological repositories and nuclear-related facilities
- Oral 4169
- Poster 4175

S4. Techniques for assessment and control of nuclide behavior in the HLW geological repository
- Oral 4180
- Poster 4188

T37. Deep-Time Digital Earth: IUGS DDE Sessions

S1. Evolution of life and biodiversity changes through deep time
- Oral 4195
- Poster 4214

S2. Quantifying plate tectonics and deformation in four dimensions
- Oral 4217

S3. Deep probing of 3D-4D lithospheric architecture and metallogenic processes
- Oral 4224
- Poster 4238

S4. Marginal Seas - Past and Future
- Oral 4245
- Poster 4261

S5. Knowledge & Data Co-boosted Discovery in the Co-Evolution of Minerals, Microbes and Environments
- Oral 4266
- Poster 4286

S6. Time Machine: Earth's deep-time geography -- data, reconstructions, challenges
- Oral 4290
- Poster 4309

S7. Geothermal Energy: Theory, Practice, and Global Opportunities
- Oral 4324
- Poster 4333

S8. Deep-time Digital Earth (DDE) – Progress, Challenges and Plans for 2024-2030
- Oral 4336
- Poster 4345

S9. Progress and Opportunities in Deep-time Paleomagnetism
- Oral 4348
- Poster 4357

S10. Geoscience Data Standards and Knowledge Graph
- Oral 4376
- Poster 4395

S11. Deep-time climate change – novel insights from paleoclimate modelling and the geologic record
- Oral 4411
- Poster 4418

S13+S14. Encouraging Early Career Scientists' (ECS) Engagement with DDE
- Oral 4422

T38. Anthropocene

S1. Anthropocene, History and the Geosciences: contributions to contemporary debates
- Oral 4430

S2. UNESCO IGCP 732 and the Stratigraphy of the Anthropocene
- Oral 4442
- Poster 4455

S3+S4. From the Holocene to Anthropocene - reading the geological and archaeological records of interplay between the nature and human
- Oral 4465
- Poster 4482

T39. Geoethics and Societal Relevance of Geosciences

S1+S2. GEOETHICS AT THE HEART OF ALL GEOSCIENCE: SERVING THE PUBLIC GOOD
- Oral 4494
- Poster 4516

T40. History of Geological Sciences

S1. History of women in the Geological Sciences: trailblazers, leaders and those in the shadows
- Oral 4520

S2. History of Geoscientific Travels in Asia and Beyond
- Oral 4532
- Poster 4553

S3+S4. General Contributions to the History of Geological Sciences
- Oral 4555
- Poster 4563

T41. Mathematical and Computational Methods for the Geosciences

S1. AI-driven mineral prospectivity mapping
- Oral 4570
- Poster 4592

S2. Fractals and Singularity in Geosciences
- Oral 4597
- Poster 4602

S3. Compositional data in geosciences: Methods and applications
- Oral 4606
- Poster 4615

S4. Geostatistical prediction and simulation for complex geological settings
- Oral 4618
- Poster 4642

S5. General Topics
- Oral 4646
- Poster 4658

T1 Sedimentary Geology

S1+3 Continental Margin Sedimentology and Environment Change		Session Chair: Scientific Program Committee			
Title	Presenter	Venue	Start	End	Page
Geochemistry and detrital zircon U–Pb geochronology of Neogene sedimentary rocks from offshore Bengal Basin, Bangladesh: Implications for provenance and tectonic setting	Julleh Jalalur RAHMAN	C105	2024-08-26 16:00	2024-08-26 16:15	17
Future drilling in Bengal Fan revealing the plateau uplift and its effects from the seafloor spreading to the climate change	Gang HU	C105	2024-08-26 16:15	2024-08-26 16:30	19
Cenozoic forearc and backarc basin-filling stratigraphy as an archive of tectonic controls on depositional styles and cycles along the north-western Pacific margins	Osamu TAKANO	C105	2024-08-26 16:30	2024-08-26 16:45	20
Geochemical Investigation in the Yellow Sea Reveals the Integration of the Modern Yellow River	Xiangtong HUANG	C105	2024-08-26 16:45	2024-08-26 17:00	22
Late Quaternary mineral magnetic record of the continental shelf sediments along the south-eastern coast of India: Implications for variations in the weathering and climate	RESHMA K V	C105	2024-08-26 17:00	2024-08-26 17:15	23
Continental weathering signal propogation in East Asian continental margins	Shouye YANG	C105	2024-08-26 17:15	2024-08-26 17:30	24
A long-term decline of δ26Mg values of clay-sized sediments in the past 430ka: the weakening of East Asian monsoon since the Mid-Brunhes Event?	Zhongya HU	C105	2024-08-26 17:30	2024-08-26 17:45	25
Re-examination the Sediments Provenance of the Eastern Sunda Slope Since the Last Deglaciation with Geochemical Methods	Junfei CHEN	C105	2024-08-26 17:45	2024-08-26 18:00	27
Holocene geomorphological evolution of a sediment-starved coastal embayment in response to sea level change: Insights from the Qing'ao Embayment, southern China	Fengling YU	C105	2024-08-27 08:00	2024-08-27 08:15	29
SEDIMENTATION AND GROWTH OF PROTEROZOIC CRATONIC BASINS: LESSONS FROM PURANA BASINS, INDIA	SHILPA PATIL PILLAI	C105	2024-08-27 08:15	2024-08-27 08:30	32
Glauconite a marker horizon for understanding paleoenvironment and depositional systems in the Mesoproterozoic Vindhyan Basin, Central India	Satya PRAKASH	C105	2024-08-27 08:30	2024-08-27 08:45	33
Extensive chemical weathering and its response to Quaternary glacialinterglacial cycles in the South China Sea: Evidence from Li isotope systematics	Fangbing LI	C105	2024-08-27 08:45	2024-08-27 09:00	35
Coupling of climate and catchment erosion in the Himalaya during the late Quaternary	Mohd AMIR	C105	2024-08-27 09:00	2024-08-27 09:15	36
Preliminary study on coupling between clinoform type and along-strike variability of shelf-edge stacking pattern	EUNHYUN CHO	C105	2024-08-27 09:15	2024-08-27 09:30	39
Inefficient burial of terrestrial organic carbon in deltas	Yonggui YU	C105	2024-08-27 09:45	2024-08-27 10:00	40
Development of submarine canyon from East Brazilian Passive Continental Margin	Daniela de Andrade MOREIRA	C105	2024-08-27 10:00	2024-08-27 10:15	41
The Chemical Weathering Record and its Responses to Climate Change and the Carbon Cycle: Insights from Sedimentary Records in Asian Marginal Seas over the Past 100,000 Years	Chao LI	C105	2024-08-27 10:15	2024-08-27 10:30	26
Marine to Continental transition in Chakrata to Rautgara Formation, Inner Lesser Himalaya (ILH), Uttarakhand, India	ALOK DEEP	C105	2024-08-27 10:30	2024-08-27 10:45	31
Relative Sea Level Controls and Depositional Dynamics in a Neoproterozoic rimmed shelf of Narji Limestone Formation, Kurnool Group, India: Insights from Facies Analysis and Isotope Signatures	RASIKH BARKAT	C105	2024-08-27 10:45	2024-08-27 11:00	37
Deep-water sedimentation controlled by interaction between bottom current and gravity flow: A case study of Rovuma Basin, East Africa	Jianan WU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	43
Li isotopic behaviors of particulate and dissolved load in the Changjiang (Yangtze River) Estuary	Chengfan YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	44
Stratigraphic architecture of the Morondava Basin (western margin of Madagascar): geo-acoustic quantification from high-resolution multi-trace seismic data	Dhishna BULJORE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	46
Lacustrine environment evolution in the Mesozoic North Yellow Sea Basin, Eastern China: insight from the transition of Jurassic grey mudstones to Cretaceous red successions	REN WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	48
An improved FT-TRA system and its application to element analysis of sediments and foraminifera	Juan XU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	49
An improved understanding of the magnetic proxies of marine sediment in the South China Sea	Meinan SHI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	50
Paleoenvironmental reconstruction of the Colombian Maastrichtian Coals: Insights from facies analysis and coal petrology. Northern Andes	Juan SEBASTIAN GOMEZ NEITA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	51
Influence and model of deep hydrothermal solution on organic matter enrichment in fault basin	zhou FANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	53
Evolution of a small forarc basin associated with the change in the plate motion: an example of the Pliocene Kakegawa Group central Japan	HARUKI SONE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	55
Sedimentary facies and evolution of fluvio-estuarine depositional system during late Pleistocene to Holocene in the Nakdong valley, southeastern Korea	Seok-Hwi HONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	56

Title	Presenter	Venue	Start	End	Page
A modern tale of the Yellow River sand: insights from provenance analysis on detrital rutile trace elements and U-Pb ages	Yuan Shang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	57
Continental crustal evolution revealed through sedimentary rocks: a case study from India	ESHA RAY	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	59
Isotopic fingerprinting of benthic dissolved iron cycling and iron sources in the Changjiang Estuary	Zhiwei HE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	61
Slope canyon evolution and its implications for gas hydrate accumulation in the northwestern Qiongdongnan Basin, South China Sea	Zigui Chen	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	63
Coupling of Source-sink System of Paleogene Enping Formation in Baiyun Sag	Zetong YU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	64
Microfacies and depositional environment of the Lower Jurassic Tagling Formation in the Spiti Valley of the Indian Himalayas	Ketan Avinash CHASKAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	66
Fine-grained turbidites in the southern Okinawa Trough and its implication for earthquakes activity over the past 700 years	Yang YAMIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	67
Identification and Sedimentary Model of Shallow-water Deltas: A Case Study of the Funing Formation, Subei Basin, Eastern China.	Ziyi Yang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	68
Stratigraphy and depositional history of the late Quaternary deposits in the inner shelf of the Korea Strait, SE Korea	Dong-Geun YOO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	69
Sandstone Petrography and Whole Rock Geochemistry of the Ashio Terrane, a Jurassic Accretionary Complex in Japan: Implications for Provenance and Tectonic Setting	Kyeongtae KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	70
Sandstone Petrography and Geochemistry of the Icheonri Formation in Gijang-gun, Busan: Implications for Provenance and Tectonic setting	Heeseon YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	72
Detrital zircon U-Pb ages of the Cretaceous Icheonri Formation in the southeastern Gyeongsang Basin, East Asian continental margin: implications for the depositional age and provenance	Ga-Yeon KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	74
S2 Black Shale Science and Economy		Session Chair: Xingliang Zhang, Dong-Chan Lee			
Facies Dependency obvious - Carbon Isotopy fails to be a stratigraphic tool within Lower Toarcian (OAE)	Hans-Joachim ROEHL	C105	2024-08-28 09:30	2024-08-28 09:45	76
Sequence stratigraphy in the middle Ordovician shale successions, mid-east Korea: Stratigraphic variations and preservation potential of organic matter within a sequence stratigraphic framework	Uk Hwan BYUN	C105	2024-08-28 09:45	2024-08-28 10:00	78
Shale lithofacies classification criteria: discussion and application	Xinyu JIANG	C105	2024-08-28 10:00	2024-08-28 10:15	79
Coupling C-N-S-P-Fe systems to reveal bottom euxinia in ancient lakes: Implications on lake-water ventilation and paleowind orientation	Xubin WANG	C105	2024-08-28 10:15	2024-08-28 10:30	80
Analysis of the Differences in Diagenetic-Porosity Evolution of Organic-Rich Shale in the First Member of Qingshankou Formation, Central Depression, Songliao Basin	min YAN	C105	2024-08-28 10:30	2024-08-28 10:45	85
Differential enrichment of organic matter in saline lacustrine black shales: an example from the Chezhen Sag in Bohai Way Basin, China	ZHI CHAI	C105	2024-08-28 10:45	2024-08-28 11:00	88
Uranium and rare-earth elements in dictyonema shale of the Baltic sedimentary basin	TIMUR DIU	C105	2024-08-28 14:30	2024-08-28 14:45	87
Composition, concentrations and strategic resources of metals in Russian black shales (Volga and Baltic sedimentary basins)	TIMUR DIU	C105	2024-08-28 14:45	2024-08-28 15:00	83
The black shale distribution pattern on the Middle Yangtze Region, South China during Ordovician-Silurian transitional period	Chuanshang WANG	C105	2024-08-28 15:00	2024-08-28 15:15	96
Application of in situ Rb-Sr geochronology for dating of black shale	Zhongwu LAN	C105	2024-08-28 15:15	2024-08-28 15:30	93
Algal δ13C reveals variations in atmospheric CO2 during the Cambrian explosion	Chao Chang	C105	2024-08-28 15:30	2024-08-28 15:45	89
Lithofacies Characteristics and Sweet Spot Distribution of Lacustrine Shale Oil Reservoirs: A Case Study of the Second Member of the Kongdian Formation in the Cangdong Sag, Bohai Bay Basin	Yuan ZHAN	C105	2024-08-28 15:45	2024-08-28 16:00	103
The marine phosphorus crisis postponed the Cambrian radiation of animals	Kang-Jun Huang	C105	2024-08-28 16:15	2024-08-28 16:30	81
Sulfate-reducing microfossil Qingjiangonema from the early Cambrian black shale of South China	Xingliang ZHANG	C105	2024-08-28 16:30	2024-08-28 16:45	92
ORGANIC GEOCHEMICAL CHARACTERIZATION OF THE LOWER GONDWANA CARBONACEOUS SHALES OF THE EAST SIANG DISTRICT IN THE ARUNACHAL HIMALAYA, INDIA	DIPJYOTI BORSAIKIA	C105	2024-08-28 16:45	2024-08-28 17:00	90
Shale gas sweet spots comparison between marine shale and transitional shale of China	Qin ZHANG	C105	2024-08-28 17:00	2024-08-28 17:15	94
Sedimentary features and their hydrocarbon significance of lacustrine shale under different hydrodynamic conditions	Zhenglian PANG	C105	2024-08-28 17:15	2024-08-28 17:30	98
Research on Seismic Response Characteristics and Prediction Methods of Shale Lithofacies Assemblages in Jiyang Depression,Bohai Bay Bain,China	Zhengchun SHEN	C105	2024-08-28 17:30	2024-08-28 17:45	100
The Carnian Pluvial Episode(late Triassic) in northeastern Tethys: Lacustrine sedimentary records,petroleum geological significance from the Yanchang Formation,Ordos Basin, central China	Xiangbo Li	C105	2024-08-28 17:45	2024-08-28 18:00	102
Analysis of favorable lithofacies for the development of lamellar sparry calcite veins in Paleogene lacustrine black shale of Jiyang Depression, China	YUNJIAO ZHANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	104

Title	Presenter	Venue	Start	End	Page
In-situ heating-induced pore structure evolution in low-medium-maturity Paleogene lacustrine shale, Bohai Bay Basin, China: Insights from integrated experimental and numerical approaches	Guoshuai Bai	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	105
Evaluation of organic matter, thermal maturity and hydrocarbon potential of source rocks from southwest of Rwanda	THEOPHILE MUGERWA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	106
Coupling of nitrogen biogeochemical cycling and phytoplankton community structure before and after the Late Ordovician mass extinction in South China	Ruining HU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	107
Depositional environment and mineralization mechanism of the gaint Ortokarnash manganese carbonate deposit in the Western Kunlun Mountains	Bang-Lu Zhang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	108
OIL SHALE OF UZBEKISTAN - COMPLEX RAW MATERIALS OF MULTI-PURPOSE	MAKSUD ISOKOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	110
Origin of Calcareous Concretion zone in the organic-rich Qusaiba Shale, Saudi Arabia	Mohamed Omar Abouelresh	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	112
The dominant lithofacies combination and genesis of the Kong2 shale in the Cangdong Depression of the Bohai Bay Basin	WEIHAO WEI LA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	113
Exploring CO2 Utilization Strategies in Shale: Enhancing Hydrocarbon Production, Sealing Efficiency, and Long-term CO2 Storage	Chioma ONWUMELU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	114
The development characteristics of continental shale laminae in China and its petroleum geological significance	Jiankang LU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	115
Sedimentary Characteristics, Distribution and Development Control Factors of Lower Cambrian Marine High Organic Matter Abundance Shale in Lower Yangtze Area	Jun WANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	117
senior engineer	baiyunfeng Yun-feng BAI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	121
Three-Dimensional Microstructure Analysis: Application of Confocal Laser Scanning Microscopy in the Study of Shale Oil Reservoir Spaces and Crude Oil Occurrence Characteristics in the Jurassic Shale	Xianda SUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	123
Provenance and environmental factors controlling deposition of organic-rich facies in the Liard Basin of the Western Canada Sedimentary Basin	Hyeonji JEON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	119
S4 Impact of volcanism on sedimentary systems		Session Chair: Scientific Program Committee			
[Keynote] Reconstructing a hyaloclastite complex: the Aci Castello hyaloclastite sequence	Andrea DI CAPUA	C105	2024-08-28 08:00	2024-08-28 08:15	129
A record of mixed carbonate and volcanic sediments in the foothills of Zelee and Geyser carbonate banks (NW Madagascar)	Dhishna BULJORE	C105	2024-08-28 08:15	2024-08-28 08:30	125
Unravelling the Influence of Volcanism on Sedimentary Systems: Insights from the Early Paleozoic World	Eelika Kiil	C105	2024-08-28 08:30	2024-08-28 08:45	127
Influence of Volcanism on the Cretaceous Depositional Evolution of Alluvial Fans and Braided Rivers in the Western Qiantang Sag, East China Sea Shelf Basin	Kailong FENG	C105	2024-08-28 08:45	2024-08-28 09:00	130
Whole-rock geochemistry and Sm-Nd-Sr isotopes of Phanerozoic shales and mudstones from the Parnaíba Basin, NE Brazil: Insights for provenance shifts in a cratonic basin, related to Mesozoic volcanism	Claudio de Morisson VALERIANO	C105	2024-08-28 09:00	2024-08-28 09:15	131
Detection of Environmental Changes Post 2011 Puhyeue-Cordón Caulle Plinian Eruption Over 13 Years	Andrea DI CAPUA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	132
Petrological, Geochemical, and Depositional Characteristics of Early Proterozoic Tuffs of Gwalior Basin, Central India	SHIKHA DIXIT	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	133
Sedimentary processes around the volcanic U Island (Jeju Island, Republic of Korea)	Federica BARILARO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	134
S5 Diagenesis and sedimentary environment		Session Chair: Scientific Program Committee			
The features and mechanisms of coral reef carbonate weathering since Miocene: evidence from Yongle Atoll in the South China Sea	Yang YANG	C105	2024-08-27 14:30	2024-08-27 14:45	139
Selective Dolomitization and Its Influence on Reservoir Heterogeneity of the Lower Cambrian Longwangmiao Formation in Sichuan basin, South China	Xuefei YANG	C105	2024-08-27 14:45	2024-08-27 15:00	146
The Main Controlling Factors on the Evolution of the Cambrian Carbonate Platform in the Tarim Basin and Its Implications for the Distribution of Ultra-Deep Dolomite Reservoirs	Kehui Zhang	C105	2024-08-27 15:00	2024-08-27 15:15	148
U-Pb geochronology, REE on detrital zircons and clast counting of the Gualanday Group and its tectonic implications for the Eocene - early Oligocene northern Andes paleogeography	María Daniela MUÑOZ-GRANADOS	C105	2024-08-27 15:15	2024-08-27 15:30	149
Role of the initial texture of carbonates on dolomitization propagation from 4D Xray tomography	Nicolas Beaudoin	C105	2024-08-27 15:30	2024-08-27 15:45	143
Cyclicity related to solar activity in lacustrine organic-rich shales and their significance to shale-oil reservoir formation	Miruo LIN	C105	2024-08-27 16:00	2024-08-27 16:15	144
Diagenetic Evolution of Coal Beds in the Sabinas Basin, NE Mexico: Insights from Fluid Inclusions Geochemistry, and Stable Isotope (δ18O, δ13C, and δ 34S) Analysis	SUMIT MISHRA	C105	2024-08-27 16:15	2024-08-27 16:30	136

Title	Presenter	Venue	Start	End	Page
Chemofacies characterization of lacustrine shale based on machine learning classification: A case study from the Dongying Depression, Bohai Bay Basin, China	Guiang LI	C105	2024-08-27 16:30	2024-08-27 16:45	135
LITHOLOGICAL PROCESSES ON THE EXAMPLE OF THE DONETSK COAL BASIN OF UKRAINE	Volodymyr BARANOV	C105	2024-08-27 16:45	2024-08-27 17:00	141
Paleoenvironmental Conditions of the Huayacocotla Basin, Mexico, During the Late Jurassic: Implications for Mn accumulation	Joseph MADONDO	C105	2024-08-27 17:00	2024-08-27 17:15	145
Reservoir characteristics and formation mechanism of the Lower Cretaceous Laiyang Group deep-water tight sandstone in the Lingshan Island, Eastern China	Tongtong CHEN	C105	2024-08-27 17:15	2024-08-27 17:30	138
Impact of Abnormal Pressure and Thermal fluid activity on Pore Evolution and Reservior Quality- A Case Study of Sandstone Reservoir from the Paleogene Shallow Marine Gravity flow, Yinggehai Basin, the South China Sea	Jinglan Lan LUO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	151
Origin of dolomite in the Middle Permian Maokou Formation in eastern Sichuan Basin under the coupling constraints of hydrothermal and karstification	Ling ZHOU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	153
Controlling factors of tight sandstone reservoirs: A case study of the He 8 reservoir in the Ordos Basin	gaixia xia CUI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	155
Sedimentary Dynamics and Paleoenvironmental Signatures in the Witbank Coalfield, Main Karoo Basin of South Africa	Lindani Ncube	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	156
Diagenetic alterations induced by lamina-scale mass transfer and the impacts on shale oil reservoir formation in carbonate-rich shale of the Permian Lucaogou Formation, Jimusar Sag	Ke LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	158
Different Sedimentation, tectonism, diagenesis of ultra-deep tight sandstone reservoirs and its relationship with reservoir quality: a case study of Dabei Gas field in Kuqa Depression, Tarim Basin	Xiaotong XU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	159
Differential precipitation mechanism and their effects on the reservoir quality of alkaline diagenetic environment in the tight Middle Jurassic sandstone in the Central Sichuan Basin, SW China	DONG PING TAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	161
The coupling relationship between sandstone reservoir densification time and hydrocarbon charging time: A case study of the Yanchang Formation in South Ordos Basin, China	Zhen Wang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	163
Mineral dissolution-precipitation mechanism in ultra-deep clastic rock reservoirs: a case study under the temperature and pressure background of Bashijiqike Formation of Kuqa Depression, Tarim Basin, China	Bing WU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	165
Diagenesis and reservoir quality prediction of Jurassic sandstones, central Junggar Basin, NW China	Penghui ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	166
The Characteristics and Genetic Mechanisms of the Lower Paleozoic Carbonate Reservoirs in South Yellow Sea Basin	Yu ZHENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	167
Origin of the carbonate cements in the upper Miocene Huangliu Formation in the Ledong Area, Yinggehai Basin, China	xuezhe LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	169
Evidence of deep fluid activity in Jurassic tight sandstone reservoirs in the Northern Kuqa Depression	Yifan Zhang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	171
Diagenesis and Evolution of lacustrine carbonate reservoir in the Upper part of the Fourth Member of the Shahejie Formation in the Gentle Slope Belt of the Bonan Sub-sag, Jiyang Sub-basin	Jie Yu DU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	172
Origin Mechanism and Favorable Area Prediction of Scale-Type High-Quality Carbonate Reservoirs in the South Yellow Sea Marine Basin, China	Ying GUO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	174
Characteristics and origin of multistage chlorites in tight sandstone reservoirs of the Upper Jurassic Qigu Formation in Yongjin Area, Junggar Basin, China	Xinyuan HUANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	175
Dolostone Petrology: Unveiling the past through a multi-method thin-section observation	Jino PARK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	176
S6 Paleoenvironments of the early Paleozoic world		Session Chair: Cristiano P. Galeazzi, Jusun WOO			
The Miaolingian Series (Middle Cambrian) in Southern Sweden: Astronomical forcing, biostratigraphy, and carbon isotope geochemistry.	Valentin Jamart	C105	2024-08-29 08:00	2024-08-29 08:15	178
Paleoclimate, provenance and depositional environment of Permo-Triassic sediments of Satpura Gondwana Basin, Madhya Pradesh, India.	Ranjit Khangar	C105	2024-08-29 08:15	2024-08-29 08:30	180
Detrital zircon geochronology of the basal Taebaek Group: Implications for regional scale provenance dynamics during the initial stage of the North China Platform	Donghyeok KANG	C105	2024-08-29 08:30	2024-08-29 08:45	182
Integrated Ichnological, Sedimentological and Geochemical Studies of the Cambrian Kunzam La Formation from Tidong Valley (Kinnaur), Himachal Himalaya: reconstructing the Northern Margin of the Indian Plate	Ranveer Negi	C105	2024-08-29 08:45	2024-08-29 09:00	183
Sedimentological and Geochemical Characterization of the Early Cambrian Eastern Yunnan, SW China	Xiaoxia PENG	C105	2024-08-29 09:00	2024-08-29 09:15	185
Spatial variation in carbonate carbon isotopes during the Cambrian SPICE event across the eastern North China Platform	ZHAOPENG WANG	C105	2024-08-29 09:15	2024-08-29 09:30	186

Title	Presenter	Venue	Start	End	Page
Floating astronomical time scale from the Upper Yangtze Region of South China suggests rapid paleoevnironmental variations during the Hirnantian glaciation	Hanyu ZHU	C105	2024-08-29 09:30	2024-08-29 09:45	188
Recycling of the Appalachian Signature in DZ U-Pb Records of Phanerozoic North America and Barriers to Transcontinental Sediment Transfer	Isaac ALLRED	C105	2024-08-29 09:45	2024-08-29 10:00	190
Stratigraphy and Carbonate Petrology of Permian Thitsipin Formation, Ywa-ngan Township, Myanmar: Implications for Depositional Environment	KYI MAW	C105	2024-08-29 10:00	2024-08-29 10:15	177
A dendrolite reef in a Cambrian siliciclastic environment, Sesong Formation, Taebaeksan Basin	Jusun WOO	C105	2024-08-29 10:15	2024-08-29 10:30	187
Provenance changes of the lower–middle Cambrian successions in the Taebaek Group, Korea: Environmental controls on source rock changes	Hyojong LEE	C105	2024-08-29 10:30	2024-08-29 10:45	189
Depositional environments of the Dongjeom Formation (upper Cambrian to lower Ordovician) in the Taebaeksan Basin in North China Platform: spatial heterogeneity of facies in wave-dominated shallow marine environments	Seungbeom AHN	C105	2024-08-29 10:45	2024-08-29 11:00	191
Preliminary study of spatiotemporal variability of sandstone compositions for early Paleozoic sandstones in the Bowers Terrane, northern Victoria Land, Antarctica	HONGWOO KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	192
Provenance of Detrital Zircons in Zealandia: Implications of a Musgrave Province Source and Potential Link to the MAPCIS Impact"	Daniel Patrick CONNELLY	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	193
Unveiling the geological significance of the Northern Gondwana glaciofluvial deposit: A geochemical approach by coupling rare-earth element and trace element geochemistry	Adhipa Herlambang Pamularso	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	194
Late Sinian-Early Paleozoic Lithofacies Paleogeographic Characteristics and Exploration Significance of the South Yellow Sea Basin, China	Ying GUO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	195
S7 General Topics in Sedimentary Geology		Session Chair: Sang Hoon LEE, Hyung Rae JO			
Sedimentation history and U-Pb detrital zircon age from Paleoproterozoic Mahakoshal back-rift basin developed during the evolution of Central Indian Tectonic Zone, India	ADITI SHARMA	C105	2024-08-29 14:30	2024-08-29 14:45	198
Petrographic and geochemical characteristics of Paleoproterozoic shales of the Limbunya Group: Implications on paleo-environment conditions.	Ananyaa Deepak	C105	2024-08-29 14:45	2024-08-29 15:00	202
Paleoweathering, Provenance and Tectonic Settings of Mesozoic Succession of Mundhan Dome (MD), Jhuran Formation, Kachchh, Western India: Insights from Petrography and Geochemistry	Poonam Rajeshbhai MANGTANI	C105	2024-08-29 15:00	2024-08-29 15:15	212
Temporal and spatial variations in sediment provenance in the Gunsan Basin, Yellow Sea	JUNHYUK SEO	C105	2024-08-29 15:15	2024-08-29 15:30	217
Tracking Middle and Late Jurassic environmental and sea-level changes in tropical Tethys Ocean	Antun HUSINEC	C105	2024-08-29 16:00	2024-08-29 16:15	200
The paleotectonic and paleogeography reconstructions of the Tarim basin during the Neoproterozoic	Bizhu HE	C105	2024-08-29 16:15	2024-08-29 16:30	196
Millennial scale marl-limestone rhythmites in the Middle Cambrian (500 My) Marjum Formation (Utah, USA) and their modulation by Milankovitch cycles	Damien PAS	C105	2024-08-29 16:30	2024-08-29 16:45	205
Paleoclimate evolution of the lower fourth sub-member of the Shahejie Formation in Niuzhuang Subsag during deposition	Rongkun LI	C105	2024-08-29 16:45	2024-08-29 17:00	215
Characterization and Development Patterns of Different Types of Karst Fracture-Cave Systems under Multi-Factor Controls: A Case Study of the Lungu 7 Area in the Tarim Basin.	Xiangbo ZHANG	C105	2024-08-29 17:00	2024-08-29 17:15	207
MODELING HYDROCARBON SYSTEMS USING AN EXAMPLE SOUTH TORGAY SEDIMENTARY BASIN (KAZAKHSTAN)	Araibek ZHIYENGALIYEV	C105	2024-08-29 17:15	2024-08-29 17:30	209
Formation of diamictite by fault-controlled redeposition of concretions	Dmitrii ALEKSANDROV	C105	2024-08-30 08:00	2024-08-30 08:15	204
Microbial induced sedimentary structures (MISS) from the Paleoproterozoic Gwalior basin, Central India	PRITAM PAUL	C105	2024-08-30 08:15	2024-08-30 08:30	206
Depositional characteristics of a braided river-type alluvial fan controlled by a small syndepositional fault	mingyue LI	C105	2024-08-30 08:30	2024-08-30 08:45	214
Depositional characteristics of Cretaceous carbonate tidal channels in southern Iraq	Zihao LIU	C105	2024-08-30 08:45	2024-08-30 09:00	216
RIVER SCALE AND CHANNEL PATTERNS IN THE ROCK RECORD	Cristiano GALEAZZI	C105	2024-08-30 09:00	2024-08-30 09:15	211
Campanian-Maastrichtian Paleoenvironmental and Sequence Stratigraphic Dynamics in the Southern Bida sub-basin, Nigeria: Insights from Sedimentology and Microfossils Studies.	Tope Shade ALEGE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	219
Northward subduction-accretion of the Bangong-Nujiang Meso-Tethys Ocean, Tibetan Plateau	Yiming LIU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	220
Deep marine siliciclastic sedimentation in a mélange zone: an example from the Late Cretaceous Fayah Formation in Batain Mélange, Northeastern Oman	IFTIKHAR AHMED ABBASI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	221

Title	Presenter	Venue	Start	End	Page
Proposal of new gravel shape indicator by the 3D principal component analysis of fluvial gravels and assessment of its accuracies in detecting the fluvial geomorphology	Tomoo YOKOYAMA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	223
Geochemical and statistical evaluation of Late Jurassic to early Cretaceous sandstones in the Bredasdrop sub-basin: Compositional signatures and provenance lithologies	Mogammad Yaaseen HENDRICKS	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	225
Detrital zircon U-Pb geochronology and geochemistry of Carboniferous sedimentary rocks from the Kharkhorin terrane, Central Mongolia	Erdenechimeg DAVAAJAV	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	227
Preliminary study of the Jurassic Bansong Group in the Yeongwol area	Sang-eon PARK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	229
Geochemistry and detrital zircon U-Pb geochronology of metasedimentary rocks of the Sergelen formation in Central Mongolia: Implications for their provenance and tectonic settings	Oyunchimeg TUMEN-ULZII	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	230
STATE OF THE ART OF THE JUMA FORMATION, ALTO TAPAJÓS GROUP, AMAZONAS STATE, BRAZIL: STRATIGRAPHIC REMARKS AND ITS IMPACT ON THE STUDY OF THE ALTO TAPAJÓS BASIN	Rodrigo Rodrigues ADORNO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	231
Mineralogy, and Trace and Rare Earth Element geochemistry of the Paleoproterozoic Karri Ironstone, Bijawar Basin, India: Implications for the genesis	Sushree Sangita PAL	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	233
Current-controlled sedimentation in the Charlie Gibbs Fracture Zone (North Atlantic)	Evgenia DOROKHOVA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	234
Contourite drifts in the South-Eastern Baltic Sea	DMITRY DOROKHOV	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	236
Comparison of Middle Permian sedimentary characteristics and stratigraphy in the northern and southern typical sag areas of the East Junggar Basin,North China	Keting Fan	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	238
Sedimentological characteristics and surface microtextures of quartz grains in modern sediments of the Hantan River, South Korea	Soyoung BAEK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	240
Source rock determination of detrital quartz grains by utilizing the Voigt peak separation of cathodoluminescence spectrum and fabric textures.	Naoya Miyashiro	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	241
Autogenic Oscillation of Grain-Size Transitions under Constant Sea-Level Rise-Flume experiment and Computational Modeling	Jaehyung LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	243
Geochemistry of Phosphatic Nodule within shale of Kopili Formation, Litang Valley, East Jaintia Hills, Meghalaya, India: Implications on Provenance	SHUBHAJIT KAR	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	244
Geochemistry and petrography of Middle Jurassic Nariinsukhait sandstone: Implications for paleoclimate and provenance	Baigalmaa NOROV	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	246
Retreat of the fan margin in an alluvial fan	Haein Shin	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	247
Pelagic carbonate sections across the Faraoni Oceanic Anoxic Event in the Umbria-Marche Basin (Apennines, Italy)	Xavier DEVLEESCHOUWER	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	248
Temperature Effects on Ripple Migration and Bedload Transport Rates: Flume experiments	Sejin KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	250
Parvancorina :The anchor-shaped Ediacaran organism from Sonia Sandstone Formation of Marwar Supergroup, India	HUKMA RAM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	251
Quantitative characterization of 3D pore structures and percolation characteristics in bioturbated reservoir media based on x-ray micro-CT: a case study of the neogene sanya formation in the Qiongdongnan basin, northern south China sea	Yongbin NIU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	252
Identification characteristics of barrier sandstones of Benxi Formation in Ganquan-Fuxian area in the Ordos Basin China	Renhai PU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	253
Provenance and source area weathering of sandstones from the Tarkwaian group at the northeastern extent of the Paleoproterozoic Ashanti belt, Ghana: Constraints from petrography and geochemistry.	Victor SEDZIAFA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	254
The Sedimentary Characteristics of the Braided River Delta of the Triassic Lower Oil Group in the Block 9 area of the Tahe Oilfield	zhao lei	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	256
Three dimensional distribution characteristics of physical property with sedimentary depth in the Ulleung Basin of the East Sea: based on downhole logging data	Gil Young KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	257
Characteristics of Mesozoic Reservoirs in Gaoqing Region	Xiaolong CHEN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	258
Sedimentary Characteristics and Controlling Factors of Biogenic Limestone in the Middle Part of the First Member of the Shahejie Formation, Shanghe area, Huimin Sag	Yu HU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	260
Effect of floodplain morphodynamics on channel avulsion: Outcrop observations of the Cretaceous Tando and Namyang basins in the mid-western part of the Korean Peninsula	Kyungjin LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	261
Characteristics of Mesozoic reservoir development in Gubei Sag	hongwei RANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	262
EPHEMERAL DEPOSITIONAL SETTING OF THE RED SANDSTONE IN THE SONIA FORMATION OF MARWAR SUPERGROUP, INDIA	PRAKASH BABU LAL	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	264
Provenance of sediments offshore northern Colombia as evidenced by detrital zircon U-Pb study of modern sediments (Magdalena River Delta and la Aguja Canyon)	Yamirka ROJAS-AGRAMONTE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	265

Title	Presenter	Venue	Start	End	Page
A high-resolution sequence stratigraphic framework of the Mississipian coastal system of the Poti Formation, Parnaíba basin, Brazil	Matheus DENEZINE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	267
Distribution and environment changes of sand ridges on the southern shelf of Korea	Eun-Je JEONG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	269
Stratigraphic and sedimentological study on the Pohang Basin, SE Korea	TAEYEON KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	270
T2 Quaternary Geology					
S1 Mapping the Quaternary geology: from detailed regional mapping campaigns to small-scale compilations		Session Chair: Scientific Program Committee			
[Keynote] Biostratigraphical data to unravel and map the early Middle Pleistocene	Thijs VAN KOLFSCHOTEN	M218	2024-08-26 16:00	2024-08-26 16:30	280
Building the GIS of International Quaternary Map of Europe and Adjacent Areas (IQUAME2500): Connecting and Harmonising the European Quaternary Geology without Political Boundaries	Kristine E.C. ASCH	M218	2024-08-26 16:30	2024-08-26 16:45	271
A GIS Approach to Quaternary Glacial Geomorphology in Slovenia	Miloš BAVEC	M218	2024-08-26 17:00	2024-08-26 17:15	279
Evolution of Middle Ganga Alluvium In Parts of Ghaghara Sub- Basin, India Gajendra Nath Dwivedi* and Subodh Kr. Sharma. Lucknow and Nagpur**	Gajendra Nath Dwivedi	M218	2024-08-26 17:15	2024-08-26 17:30	282
Exploring Neotectonics and Seismicity during the late Quaternary in the vicinity of Gish fault in Darjeeling-Sikkim Himalaya through PGRS, MEQ, DGPS and OSL dating	RITU Pragya	M218	2024-08-26 17:30	2024-08-26 17:45	273
Mapping the retreat of the Laurentide Ice Sheet in the western Gulf of St. Lawrence (Eastern Canada)	Patrick Lajeunesse	M218	2024-08-26 17:45	2024-08-26 18:00	275
Reconstructing the glacial lakes of northern Quebec and Labrador (Canada) through field-based mapping and GIS modeling	Martin ROY	M218	2024-08-26 18:00	2024-08-26 18:15	277
The Geoscience of Wine: The influence of surficial geology on viticulture in Atlantic Canada	MITCH J MARACLE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	284
Snapshots of glacial forefields: mapping modern-day processes in central Chilean Patagonia	Paulina MEJÍAS OSORIO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	285
The Quaternary geological map production in Korea	Jin Cheul KIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	286
S2 Present Earth Surface Processes and Long-term Environmental Changes in East Eurasia		Session Chair: Noriko Hasebe, Jin Cheul KIM			
[Keynote] Exploring Desert Margins: Interdisciplinary Insights into Climate Dynamics, Human Migration, and Environmental Change	HEMA ACHYUTHAN	M218	2024-08-27 14:30	2024-08-27 14:50	293
On acquisition of natural remanent magnetizations in tidal depositional setting: insight from a Holocene tidal mud sediment in the southwestern coast of the Korean Peninsula	Hyeon-Seon AHN	M218	2024-08-27 14:50	2024-08-27 15:05	288
Sea surface temperature variations at Shushi bay in Tsushima island over the last 3 ka	Sujeong PARK	M218	2024-08-27 15:05	2024-08-27 15:20	289
The environmental dynamics studied in Boontsagaan lake, southwestern arid Mongolia: lake sedimentation and catchment erosion	Noriko HASEBE	M218	2024-08-27 15:20	2024-08-27 15:35	290
Reconstruction of Sedimentary Environment on the Western Shelf of the South China Sea since the last deglaciation	Yang LI	M218	2024-08-27 15:35	2024-08-27 15:50	291
[Keynote] Sahara's surface transformation forced an abrupt hydroclimate decline and Neolithic culture transition in northern China	Hao LONG	M218	2024-08-27 16:05	2024-08-27 16:25	300
Luminescence Dating Holocene Sediments from the Mongolian Forest Steppe	Manfred FRECHEN	M218	2024-08-27 16:25	2024-08-27 16:40	295
Exploring palynofacies and sediment texture dynamics in subtropical floodplains along the Gomati River, Lucknow, India: Transition from Suburban to Urban Environments	POOJA TIWARI	M218	2024-08-27 16:40	2024-08-27 16:55	299
Typhoon variability during the Holocene in East Asia and its linkage to ENSO activity	Jaesoo LIM	M218	2024-08-27 16:55	2024-08-27 17:10	306
Taxonomic research on the Cenozoic gastropods from Qaidam Basin and their palaeoenvironmental significance	Tingting YU	M218	2024-08-27 17:10	2024-08-27 17:25	302
The Geological Evolution and Palaeoclimatic Significance of the Temburong Peatland, Brunei Darussalam	Adlina MISLI	M218	2024-08-27 17:40	2024-08-27 17:55	303
Insights into the Palaeoclimatic and Palaeoenvironmental Evolution of Brunei Darussalam through the Window of Tasek Merimbun Peatland	Basilios TSIKOURAS	M218	2024-08-27 17:55	2024-08-27 18:10	304
Age dating of lava plateau and paleolake sediments formed by dammed lava plateau in Yeoncheon, the center of Korean Peninsula	JIEUN KWON	M218	2024-08-27 18:10	2024-08-27 18:25	297
Sr-Nd isotopic composition of the Quaternary brown clay-silt sequences in the Jeongok Paleolithic site, Korea: Implication for sediment provenance	Hawon YUN	M218	2024-08-27 18:25	2024-08-27 18:40	301
Tracking the appearance of the first humans on the Jeongokri, Korea	Jin KIM	M218	2024-08-27 18:40	2024-08-27 18:55	305
Holocene landscape variations of a large shallow lake in East Asia: Interactions between climate, hydrology, and human beings	Yawen GE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	307
Uplift of the northeastern Tibetan Plateau leads to the extreme desertification in East Asia around 0.9 Ma	Xinbo GAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	308
Limnological shift and droughts driven by monsoonal changes during the Holocene – insight from a diatom record from Biển Hồ maar lake, Central Highlands of Vietnam	Hoàn Đào-Trung	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	309

Title	Presenter	Venue	Start	End	Page
New data on the glacial history of the Southern Pamir	Mariia Efimova	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	310
Paleoenvironment evolution in the Weihe basin and its impacts on drainage systems of middle Yellow River since late Pliocene	Jingyun XIAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	311
Incised-valley filling Sedimentation in response to Holocene Sea Level rise, Yeongil Bay, Southeastern Korea	Hyun Ho YOON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	312
Paleo-hydro environmental changes in Southeastern Mongolia from the Late Pleistocene to the Mid-Holocene: An analysis of lake sediment from Bayan Tohom Gobi	Sumin KANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	313
Reconfirmation of the dating of Jeju Island's Suwolbong Tuff	youjin WOO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	314
S3 Current and future directions in Quaternary chronostratigraphy		Session Chair: Martin J. Head, SPC			
Fluvial dynamics and climate change in a tropical river throughout the Late Quaternary (Kampar River, Sumatra, Indonesia)	Yuniarti YUSKAR	M218	2024-08-27 08:00	2024-08-27 08:15	317
Dating the base of the Upper Pleistocene in Chinese and Tajik loess by OSL and its association with climatostratigraphy and chronostratigraphy	Liping ZHOU	M218	2024-08-27 08:15	2024-08-27 08:30	319
A ~426 ka Antarctic methane jump at the onset of MIS 11 could mark a prospective second stage for the Middle Pleistocene Subseries	Martin J. James Head	M218	2024-08-27 08:30	2024-08-27 08:45	320
Date your late Cenozoic mud: New advances in applicability of the authigenic 10Be/9Be dating	Michal ŠUJAN	M218	2024-08-27 08:45	2024-08-27 09:00	323
CENOZOIC STRATIGRAPHY OF SOUTH AFRICA: CHALLENGES AND POSSIBILITIES	Greg A. Botha	M218	2024-08-27 09:00	2024-08-27 09:15	322
Electron Spin Resonance chronology and heavy minerals from the quaternary fluvial terraces of the Somme River (Northern France)	Rajib Kumar SAHA	M218	2024-08-27 09:15	2024-08-27 09:30	315
Unravelling the chronology of the infill of glacially overdeepened structures in the northern foreland of the European Alps.	Gustav FIRLA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	325
Inception of the European Ice Sheet revealed by cosmogenic nuclide dating in Lithuania: First results of the CosmoLith project	Michal ŠUJAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	327
S4 A global perspective on the Neogene–Quaternary (Pliocene–Pleistocene) boundary		Session Chair: Scientific Program Committee			
[Keynote] Paleoenvironmental changes across the Neogene–Quaternary boundary at the Monte San Nicola GSSP, near Gela, Sicily – an update of the international program GELSTRAT	Martin J. James Head	M218	2024-08-28 08:00	2024-08-28 08:15	331
'Nicola' bed deposition at the onset of the Quaternary ~2.58 Ma, Monte San Nicola, southern Sicily – geological background	Wieslawa RADMACHER	M218	2024-08-28 08:15	2024-08-28 08:30	329
Vegetation dynamics and climate changes during the Onset of Northern Hemisphere Glaciation: Insights from the Monte San Nicola Section (central Mediterranean)	Adele BERTINI	M218	2024-08-28 08:30	2024-08-28 08:45	333
Some problems of Pliocene – Pleistocene sediment studying at the East Siberian Sea according pollen data	Ekaterina NOSEVICH	M218	2024-08-28 08:45	2024-08-28 09:00	335
Climate variability and biotratigraphic constraints at the Neogene–Quaternary boundary at the Monte San Nicola type-section, Sicily	Adele BERTINI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	338
Palynological implications for paleoenvironmental changes in the continental shelf, southeastern Korea, during the Plio-Pleistocene climate transition	Yongmi KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	340
Hydrographic development of the northern South China Sea during the Pliocene–Pleistocene transition: The dinoflagellate cyst record of ODP Site 1148 – Preliminary results	Martin J Head	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	336
S5+S8 Geological Sea-level Proxies of Marine Isotopic Stage (MIS) 5 in the Asian Shorelines		Session Chair: Scientific Program Committee			
Continuous measurements in north China and culture experiments reveal the potential of leaf n-alkane carbon isotopes in paleoclimate studies	Guoan WANG	M218	2024-08-28 14:30	2024-08-28 14:45	341
Fire history of the Chinese Loess Plateau under extreme warming scenarios: a case study of the loess-paleosol sequence L5-S5	lian LIU	M218	2024-08-28 14:45	2024-08-28 15:00	342
Carbon cycle and carbon isotope fractionation during the snail assimilation process	xuefen SHENG	M218	2024-08-28 15:00	2024-08-28 15:15	343
Late Pleistocene and Holocene Landscape Evolution in the White River Badlands, Great Plains, USA	patrick albert burkhart	M218	2024-08-28 15:15	2024-08-28 15:30	345
Integrated multi-geochemical analysis for reliable 14C age of artificial carbonates	Zhanpeng Chen	M218	2024-08-28 15:30	2024-08-28 15:45	346
A newly revised record of relative sea-level changes in western Philippines, Southeast Asia during the past 125 ka deduced from uplifted coral reef terraces	Kathrine MAXWELL	M218	2024-08-28 15:45	2024-08-28 16:00	348
Hydroclimate changes during the Meghalayan Stage and its global teleconnection from Southern India	Upasana BANERJI	M218	2024-08-28 16:00	2024-08-28 16:15	350
EVIDENCES OF LATE-QUATERNARY SEA-LEVEL CHANGES IN CENTRAL KERALA, SOUTH INDIA	Shaima M	M218	2024-08-28 16:15	2024-08-28 16:30	352
Variability of leaf wax n-alkanes across gradients of environment and plant functional type in China	Yutao ZHOU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	353

Title	Presenter	Venue	Start	End	Page
Last and Holocene interglacial relative sea-level rises and coastal sedimentation in the Korean Peninsula	Woo Hun RYANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	354
New Geochronological Data on the Tatun Volcano Group in Northern Taiwan	Su-Chin CHANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	355
A modern pollen-climate dataset from South Korea for palaeoclimate reconstruction	Jaeyoung LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	356
Surface microtextures of quartz grains in soil of Chuncheon Basin	Eun-chae SHIN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	357
The preliminary study of reconstructing abrupt climate shift with speleothem in Korean Peninsula: a textural approach	Jungwon CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	358
Where ice meets salt: A more than 800 m deep glacial basin in the European Eastern Alps (Salzkammergut region, Austria)	Clemens SCHMALFUSS	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	359
Millennial to seasonal trace element variability within stalagmite fluorescence banding during the Last Interglacial	Jihye KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	361
Paleoenvironmental evolution since the late Quaternary from core YZ02 in the South Yellow Sea	XIA LIAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	362
S6 Youngest Quaternary (Meghalayan Stage) Speleothems and global Paleoclimate events		Session Chair: Scientific Program Committee			
[Keynote] Holocene Meghalayan Stage Speleothem (Stalagmite) carbonate petrography and paleoenvironmental significance from Meghalayan and Lesser Himalayan caves, India	HEMA ACHYUTHAN	M218	2024-08-27 09:30	2024-08-27 09:45	367
Monsoon Mysteries Unveiled: Traversing Millennia Through Climate Reconstructions in Southern India	HEMA ACHYUTHAN	M218	2024-08-27 09:45	2024-08-27 10:00	363
Comparison between a stalagmite record and a peat record over the past 14 Ka from NE China: To what extend the proxies in stalagmite and peat records to reflect climate changes	Hong-Chun Li	M218	2024-08-27 10:00	2024-08-27 10:15	369
Reconstruction of Holocene Climatic Dynamics in the Western Himalaya: Speleothem Record	Jaishri BHATT	M218	2024-08-27 10:15	2024-08-27 10:30	365
Signatures of trace element variations in the Indian speleothem from the core monsoon zone during the late Holocene	Naveen GANDHI	M218	2024-08-27 10:30	2024-08-27 10:45	371
Meghalayan Stage Stalagmites , Indian Summer Monsoon and Paleoclimate records from Northeast India	POOJA BHARALI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	372
Seismic Impact on Speleothems and Cave Structures: Evidence for Major Earthquakes in the Central Himalaya	Jaishri Sanwal BHATT	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	374
Small mammal fossils from cave sediments and their use for palaeoenvironmental reconstructions. Potential and limitation	Lutz Christian MAUL	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	376
Past-WDs modeling using CMIP6 Paleoclimate Modeling Intercomparison Project (PMIP4) Experiments and Speleothems Over Hindukush Himalaya.	Pramod KUMAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	378
Evidence from southern India suggests that the Little Ice Age was not uniformly cold and dry across the globe.	ISHFAQ AHMAD MIR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	379
S7 New Advances in Paleolithic Sites and Early Human Settlement		Session Chair: Xuefeng Sun, SPC			
[Keynote] New Palaeolithic Explorations in Eastern Asia	Shixia YANG	M218	2024-08-28 09:30	2024-08-28 09:45	380
Early Holocene human in the Tengger Desert, northern China	xuefeng SUN	M218	2024-08-28 09:45	2024-08-28 10:00	381
New OSL dating reveals interactive migrations of Western and indigenous populations in north China corresponding to monsoonal fluctuations during the past 70-10 ka	JUNYI GE	M218	2024-08-28 10:00	2024-08-28 10:15	382
Discovery and research at Xuetangliangzi in the Yunxian hominin site, central China	Chengqiu LU	M218	2024-08-28 10:15	2024-08-28 10:30	384
T3 Earth History and Stratigraphy					
S1 Evolution of habitability of the early Earth		Session Chair: Ruimin Wang, SPC			
[Keynote] The expansion of marine eukaryotes in the early Neoproterozoic Era	Shuhai Xiao	C106	2024-08-26 16:00	2024-08-26 16:15	392
A tale of two widespread Proterozoic fossils: Chuaria and Tawuia assemblage from ~1.0 Ga rocks in North China	Ke PANG	C106	2024-08-26 16:15	2024-08-26 16:30	385
Discs from Tonian rocks in North China: Relating discoidal fossils with a central opening to worm-like annulated tubular fossils and their paleoecological and evolutionary implications	Guangjin LI	C106	2024-08-26 16:30	2024-08-26 16:45	387
Symbiotic fossils from the early Ediacaran in South China and their implication for lichenization and bio-weathering	Hanzhi Qu	C106	2024-08-26 16:45	2024-08-26 17:00	389
Stromatolites improved the habitability of Precambrian seafloor: Evidence from the molar-tooth structure in the Tonian Jiudingshan Fm., North China	Xubin WANG	C106	2024-08-26 17:00	2024-08-26 17:15	390
Large magnitude sulfur isotope mass independent fractionation indicating subaerial volcanism in 3.8 Ga	Ruimin WANG	C106	2024-08-26 17:15	2024-08-26 17:30	391
Abiotic Sulfur Cycling Model Across Deep Time	Javed Akhter MONDAL	C106	2024-08-26 17:30	2024-08-26 17:45	394
Unique Archean phosphorous cycle linked to submarine hydrothermal and biological activities	Takeshi KAKEGAWA	C106	2024-08-26 17:45	2024-08-26 18:00	393
What happened in Mesoarchean during earth history? Evidence from western Dharwar craton, southern India	Yan ZHAO	C106	2024-08-26 18:00	2024-08-26 18:00	395

Title	Presenter	Venue	Start	End	Page
Molybdenum isotope and oceanic redox evolution during the Cryogenian non-glacial period	Jin LI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	397
New discovery of rare 3.8 Ga crust in Labashan, eastern China: Petrogenesis and significance	Chunyan DONG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	399
Redox-stratified seawater during the GOE: Evidences from rare earth elemental and C-O isotopic compositions of Paleoproterozoic BIFs and carbonate rocks from the Taihua Group, North China Craton	Cai YUN LAN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	401
Preliminary observations of fulgurites: prebiotic sources of reduced phosphorus on early Earth	DongJun KIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	402
The coming and going of banded iron formation	Bing SHEN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	403
Overlooked role of dissolved ferrous iron in the adsorption of phosphate by clay minerals: Implications for phosphorus cycling on the early Earth	Xing CUI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	404
Preservation of early life molecular signatures in a ~2.5 Ga banded iron formation, North China	Jingbo NAN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	400
S2 The Neoproterozoic-Lower Paleozoic stratigraphy, sedimentation, paleoclimate, chemostratigraphy and correlation of the Southwest and East Gondwana		Session Chair: Scientific Program Committee			
Cr-Cd isotopes track redox and nutrient conditions during the rise of biomineralizing organisms: The Ediacaran Taguatiya Guazú Fm., Paraguay	Fabricio CAXITO	C106	2024-08-27 08:00	2024-08-27 08:15	405
Ediacaran diamictites and glaciation in North China	Yongqing LIU	C106	2024-08-27 08:15	2024-08-27 08:30	407
Was there a palaeo-ocean in South China during the late Tonian to Cambrian? – Evidence from provenance variation across the Xiang-Gui-Yue Basin	Yang TIAN	C106	2024-08-27 08:30	2024-08-27 08:45	408
Discussion on a lectostratotype proposal for the Ediacaran Sete Lagoas Formation, Bambuí Group, Brazil	Matheus DENEZINE	C106	2024-08-27 08:45	2024-08-27 09:00	410
Ediacaran-Cambrian transition events in the peninsular India: Insights from isotope stratigraphy and geochronology of Bilara carbonates, Marwar Supergroup	Bivin GEORGE	C106	2024-08-27 09:00	2024-08-27 09:15	409
Orbitally-paced carbon-isotope excursion and sedimentary rate during the middle-late Cambrian	Jixuan WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	412
Multiple glacio-eustatic cycles through the Hirnantian (Late Ordovician) in South China: correlations between the nearshore and offshore outcrops	Chao LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	413
The sedimentary characteristics and stratigraphic framework of the Cryogenian in the northwestern Yangtze Craton	Xiaoshuai CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	415
Sedimentology and timing of the Klipheuwel Group, South Africa – anatomy of a Cambrian-Ordovician failed rift in southwest Gondwana	Ruan Francois RAATH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	417
Application of the Wavelet Transform coupled with Fischer plots and INPEFA in Sequence Stratigraphy	Yu ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	419
Geochronological constraints of high-grade metasedimentary rocks of the Italva and Costeiro basins: Reconstructing the Outer Magmatic Arc System of the ribeira belt, SE Brazil	Caroline de Araujo PEIXOTO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	421
S3 Evolution of Earth surface system from the Carboniferous to the Triassic		Session Chair: Scientific Program Committee			
The selection of the Global boundary Stratotype and section (GSSP) for the Carboniferous Moscovian Stage	Keyi HU	C106	2024-08-27 09:30	2024-08-27 09:45	423
The Middle-Late Pennsylvanian Event: timing and mechanism	Yixin WANG	C106	2024-08-27 09:45	2024-08-27 10:00	424
Phylogeny and paleobiogeography of the Carboniferous conodont genus *Gnathodus*	Wenqi WANG	C106	2024-08-27 10:00	2024-08-27 10:15	426
Farfield effects of the Hercynian orogeny on the sedimentary succession of the Arabian Plate	Michael Stephenson	C106	2024-08-27 10:15	2024-08-27 10:30	428
Revision of Idiognathodus sagittalis (Conodonta, Pennsylvanian): 2D- and 3D-based morphometrics	Yingjun PENG	C106	2024-08-27 10:30	2024-08-27 10:45	429
The chemical weathering trend of the Carboniferous to early Permian strata in the Naqing section, South China	Biao GAO	C106	2024-08-27 10:45	2024-08-27 11:00	431
Episodic marine anoxia during highly oxygenated Late Paleozoic icehouse	Jitao Chen	C106	2024-08-27 14:30	2024-08-27 14:45	432
Mercury isotope evidence for the linkage between volcanic activity and Early Permian Artinskian Warming Event	Chaosheng YUE	C106	2024-08-27 14:45	2024-08-27 15:00	433
Zinc isotopes as a tracer for global carbon cycling during the onset of late Paleozoic icehouse	Yutian ZHONG	C106	2024-08-27 15:00	2024-08-27 15:15	434
Tipping cascades in the onset of the Carnian Pluvial Episode (Late Triassic)	Bo WANG	C106	2024-08-27 15:15	2024-08-27 15:30	438
Chaotic Mars-Earth swings in precession of orbital perihelion revealed in Jurassic lake sequences, Junggar Basin, northwestern China	Yanan Fang	C106	2024-08-27 15:30	2024-08-27 15:45	440
Carbon isotope perturbations driven by volcanism during the Late Paleozoic Ice Age (LPIA)?	Zhihui ZHANG	C106	2024-08-27 16:00	2024-08-27 16:15	441
Volcanic activities, wildfires and the collapse of tropical rainforest ecosystems during the terrestrial end-Permian mass extinction in Southwest China	Hua ZHANG	C106	2024-08-27 16:15	2024-08-27 16:30	435

Title	Presenter	Venue	Start	End	Page
Sedimentary record of the Permian Yangtze Block breakup: Evidence from the Sichuan Basin	Xuanwei LIU	C106	2024-08-27 16:30	2024-08-27 16:45	436
The state of the art on the redefinition of the Devonian/Carboniferous Boundary	Markus ARETZ	C106	2024-08-27 16:45	2024-08-27 17:00	439
S4+S5 The end-Permian mass extinction - state of knowledge and future advances		Session Chair: Scientific Program Committee			
[Keynote] The end-Permian mass extinction: Progress and unexplained questions	Shuzhong SHEN	C106	2024-08-29 08:00	2024-08-29 08:15	452
Mass Extinctions & Fossil Preservation from Organic & Inorganic Geochemical Signals	Kliti Grice	C106	2024-08-29 08:15	2024-08-29 08:30	450
Stable sulfur isotope dynamics of reduced inorganic and organic sulfur phases recorded in the Permian-Triassic transition of the Meishan type section	Paul Greenwood	C106	2024-08-29 08:30	2024-08-29 08:45	449
Sea-level and temperature changes on the Late Permian mass extinction event	Guoqiang XU	C106	2024-08-29 08:45	2024-08-29 09:00	445
Did CO2 emissions from the Siberian Traps volcanism outpace silicate weathering following the end-Permian mass extinction?	Ying CUI	C106	2024-08-29 09:00	2024-08-29 09:15	446
Vapour pressure deficit, drought, flood, fires, and CO2 spikes during the Permian-Triassic life mass extinction	Gregory RETALLACK	C106	2024-08-29 09:30	2024-08-29 09:45	453
End-Permian continental vegetation collapse directly affected marine ecosystems; Evidence from Permian-Triassic successions of Australia.	Vivi Vajda	C106	2024-08-29 09:45	2024-08-29 10:00	448
Carbon isotopic excursions around the Smithian–Spathian boundary in southern Thailand	Kittichai TONGTHERM	C106	2024-08-29 10:00	2024-08-29 10:15	442
[Keynote] Astrobiological significance of Stromatolites and organic walled microfossils on early Earth : Evidence from Lesser Himalayan Proterozoic stromatolitic cherty carbonates of India	Shuzhong SHEN	C106	2024-08-29 10:15	2024-08-29 10:30	443
Stratigraphic position of various stromatolitic successions in Nepal Lesser Himalaya	Megh Raj DHITAL	C106	2024-08-29 10:30	2024-08-29 10:45	447
Proterozoic stromatolite-bearing host rocks for nickel and cobalt mineralization in western Nepal	Sunil LAMSAL	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	454
Identification and Significance of the Permian Guadalupian-Lopingian boundary in the northwestern margin of the Yangtze Craton	Xiaoqi FAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	455
Study of Meso-Neoproterozoic stromatolites and algal structures from the Lesser Himalayan carbonates of Nepal and their depositional environment	Basanta DEVKOTA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	456
Study of the Late Permian radiolarian fauna from the Heshan Formation in Laibin, Central Guangxi Province	XiaoXin Dong	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	457
Calcification of cell membranes: From ions to minerals	XIAO GAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	458
S6 Paleogeography of the Tethys Oceans		Session Chair: Scientific Program Committee			
[Keynote] The Permian-Triassic amalgamation in the Altaids-Tethysides interaction	Wenjiao XIAO	C106	2024-08-28 14:30	2024-08-28 14:45	467
Late Paleozoic sedimentary successions and basin structure variation of the Baoshan-Shan Block (China-Myanmar)	Xiaochi JIN	C106	2024-08-28 14:45	2024-08-28 15:00	478
The Złatne/Pieniny Basin as a part of the Alpine Tethys in Central and Eastern Europe	Jan Golonka	C106	2024-08-28 15:00	2024-08-28 15:15	459
The Tethyan Seaway during the Early to Middle Miocene – new data and a review	Werner E. Piller	C106	2024-08-28 15:15	2024-08-28 15:30	461
The base of the Maastrichtian at the Oslen-Krivodol Peritethyan reference section, Bulgaria: bioevents, isotope events and paleoceanography	Michael WAGREICH	C106	2024-08-28 15:30	2024-08-28 15:45	464
The opening time constraints of both Bangong-Nujiang Ocean and Neotethys Ocean: evidences from both stratigraphy and palaeobiogeography in the Qinghai-Tibet Plateau	Yichun ZHANG	C106	2024-08-28 15:45	2024-08-28 16:00	466
Early Triassic anachronistic microbial and pisoid-facies carbonates in the eastern Paleotethys	Katsumi Ueno	C106	2024-08-28 16:00	2024-08-28 16:15	469
Late Neoproterozoic–Cambrian eclogites and high-pressure granulites in the Central Qilian terrane (China) record the earliest subduction of Proto-Tethyan Ocean in the eastern Tethysides	Hao WANG	C106	2024-08-28 16:15	2024-08-28 16:30	471
Revisiting the Structure and Stratigraphy of the Bentong-Raub Suture Zone: Insights from Field Investigation and Geochemical Analysis	Norasiah Binti SULAIMAN	C106	2024-08-28 16:30	2024-08-28 16:45	474
A PALEOENVIRONMENTAL MODEL FOR THE RUS FORMATION: FACIES CHARACTERISTICS AND THEIR SEDIMENTARY ENVIRONMENTS	Osman Abdelghany	C106	2024-08-28 16:45	2024-08-28 17:00	475
Newly discovered Late Paleozoic magmatic rocks link to Paleo-Tethyan evolution in Hainan Island, South China	Lei WANG	C106	2024-08-28 17:00	2024-08-28 17:15	477
Subduction and Obduction-Scenario structural analysis of the Indosinian orogenic belt	Wei LIN	C106	2024-08-28 17:15	2024-08-28 17:30	472
Late Paleocene-middle Eocene calcareous nannofossils in western Tarim Basin	Xuejiao WANG	C106	2024-08-28 17:30	2024-08-28 17:45	462
Deciphering Miocene Geodynamics and Sedimentation in Eastern Turkey: Insights from Plate Tectonics and Basin Analysis	Erhan Gulyuz	C106	2024-08-28 17:45	2024-08-28 18:00	480

Title	Presenter	Venue	Start	End	Page
Quantifying the Late Jurassic post-rift subsidence trends of Alpine Tethys: Constraints on the passive margin stage of the Vienna Basin area, Austria	Eun Young LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	482
Flysch and mélange in the North-Eastern Part of the Alpine Tethys	Anna WAŚKOWSKA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	484
Paleogeograpy of the Tethys oceans in South-East Asia	KhuongThe HUNG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	486
Study on coal-bearing deposits of the Lower Gosau Subgroup (Turonian to Campanian) in the Northern Calcareous Alps, Austria: High-resolution insights into the paleoenvironment	xinxuan Xiang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	487
Final amalgamation processes of the southern Altaids: insights from the Triassic ophiolitic mélange in the eastern Tianshan-Beishan orogen (NW China)	Qigui MAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	488
Early Ordovician to Early Permian tectonic evolution of the northern Western Kunlun Orogen (NW China)	Miao SANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	490
Andean-type orogenic plateau as a potential trigger for Permian aridification of North China in northeast Pangaea	Dongfang SONG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	491
Late Paleozoic and Triassic clastic rocks in the Changning-Menglian Belt: insights into paleogeography of the Paleo-Tethys in western Yunnan, China	Jianbin ZHENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	492
Zircon U-Pb age of an intermediate dike intruding into the Selenge igneous rock complex at the Jargalant Village, Northern Mongolia	Sukhbaatar PUREVDULAM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	494
The geochemical signature of the mafic rocks in the accretionary complexes of the western Khangai-Daur belt, Central Asian Orogenic belt, central Mongolia	BAYART NADMID	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	496
The last viscous coupling in the Neo-Tethys subduction plate interface	Zhou TAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	498
SEDIMENTARY RECORD OF A BASIN MARGINAL TO THE TETHYS OCEAN: THE CERGOWA BEDS (OUTER CARPATHIANS; OLIGOCENE)	Marek WENDORFF	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	500
High-resolution sequential thrust propagation in the Nepalese Himalaya: response to the Miocene anticlockwise rotation of the Indian plate	Rui LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	501
S7 Cretaceous Earth Dynamics and Climate in Asia (Joint Session of IGCP 679)		Session Chair: Gang Li, Taejin CHOI			
[Keynote] A synthesis of provenance studies of the Cretaceous Gyeongsang Basin, SE Korea and its tectonic implications for active continental margin in East Asia	Yong Il LEE	C106	2024-08-28 08:00	2024-08-28 08:30	504
Progress of IGCP 679: Cretaceous Earth Dynamics and Climate in Asia	Gang LI	C106	2024-08-28 08:30	2024-08-28 08:45	502
Vegetation response against environmental change during the Oceanic Anoxic Event 2 recorded by terrestrial plant biomarkers in sediments from the Tomamae (Hokkaido, Japan)	Masashi A. IKEDA	C106	2024-08-28 08:45	2024-08-28 09:00	508
A new Early Cretaceous bird shed new light on the evolution of avian cranial kinesis.	MIN WANG	C106	2024-08-28 09:00	2024-08-28 09:15	506
Stratigraphic, sedimentary and basin evolution and its chronological constraints on the transition from Yanliao biota to Jehol biota during the Late Meosozoic in North China	Yongqing LIU	C106	2024-08-28 09:15	2024-08-28 09:30	510
GEOCHEMICAL AND PALYNOLOGICAL ANALYSES OF THE KHOVIL COAL DEPOSIT, CHOIR-NYALGA BASIN, CENTRAL MONGOLIA	Nyamsambuu ODGEREL	C106	2024-08-28 09:45	2024-08-28 10:00	513
Development of a new silicate weathering index (RW) and its application to the Early Cretaceous strata distributed in East Asia	Tenichi CHO	C106	2024-08-28 10:00	2024-08-28 10:15	503
The sedimentological characteristics of the intermontane desert system in the Jurong Basin, South China and its relationship with the Late Cretaceous hot climate	Shuo CAO	C106	2024-08-28 10:15	2024-08-28 10:30	507
Cretaceous stratigraphy, paleogeography and major geological events in eastern Neotethys	Dangpeng XI	C106	2024-08-28 10:30	2024-08-28 10:45	512
Interpretations from detrital zircon geochronology of Lesser Himalaya strata, Nepal, regarding the Paleozoic-Mesozoic dispersal of Gondwana	Upendra BARAL	C106	2024-08-28 10:45	2024-08-28 11:00	505
Diverse microbially induced sedimentary structures (MISS) from the Cretaceous deposits of Korea: occurrences and paleoenvironmental implication	Hyun Joo KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	514
Mineral magnetic variations across an inland sea-way excursion around Late Maastrichian/Danian deposition of the Jhilmili intertrappean in the Deccan Volcanic Province, Mandla lobe, Madhya Pradesh, India.	Jyotibala SINGH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	515
Evaluation of the hinterland paleoweathering during the mid- to late-Cretaceous in Northwestern Kyusyu, Japan	Arisa NAKANO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	516
Interpretation of Cretaceous geomorphology in eastern China based on palynological data	Suping LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	517
Stable carbon isotope stratigraphy of the Tetori Group, Upper Jurassic to Lower Cretaceous siliciclastic shallow-marine to non-marine succession in central Japan: application for non-marine regional correlation	Mayuko KAMIMURA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	518
S8 General Topics		Session Chair: Scientific Program Committee			
Integrating geochemical and geochronological methods to improve geological mapping in Aus, Southern Namibia	Claudia MUTONGOLUME	C106	2024-08-29 14:30	2024-08-29 14:45	526

Title	Presenter	Venue	Start	End	Page
U–Pb Geochronology of Detrital Zircons from San Carlos Basin, Costa Rica: Evidence of Miocene Volcanism and Implications for the Precambrian and Paleozoic History of the Central American Isthmus	Martin Rojas Barrantes	C106	2024-08-29 14:45	2024-08-29 15:00	528
Research advances and a reference subdivision of the Meso-Neoproterozoic stratigraphy in China	Hongwei KUANG	C106	2024-08-29 15:00	2024-08-29 15:15	530
STRATIGRAPHIC REVISION OF AN EOCENE-MIOCENE CARBONATE-EVAPORITE SUCCESSION IN UAE-OMAN GUIDED BY SENTINEL-2 MULTISPECTRAL DATA ANALYSIS	Abdel-Rahman FOWLER	C106	2024-08-29 15:15	2024-08-29 15:30	534
Are Ordovician ferruginous ooids and microbialites indicators of cool-water realms and upwelling-active zones?	Xiaocong LUAN	C106	2024-08-29 15:30	2024-08-29 15:45	535
Meso-Neoproterozoic Simlipal Complex, Eastern India; an impact induced basin, post amalgamation of Singhbhum Craton and North Singhbhum Mobile Belt.	Jayaprakash Mohakul	C106	2024-08-29 15:45	2024-08-29 16:00	532
Provenance studies of the Cuyuja Unit in the Quebrada Yaguana, Napo-Ecuador	Christian ROMERO CÓNDOR	C106	2024-08-29 16:15	2024-08-29 16:30	538
Unravelling the Evolution of the Richtersveld Magmatic Arc: Insights from Integrated Regional Geological Mapping	Conrad GROENEWALD	C106	2024-08-29 16:30	2024-08-29 16:45	536
Continental migration does not conflict with the gyroscope	ZHAINA YERZHANOVA	C106	2024-08-29 16:45	2024-08-29 17:00	522
Expression of the Prague Event (Lochkovian-Pragian boundary) in the Carnic Alps (Italy and Austria)	Carlo CORRADINI	C106	2024-08-29 17:30	2024-08-29 17:45	525
Key findings of the geoscientific mapping in the Aukam Valley, Namaqua Metamorphic Complex, Southwestern Namibia	Ewereth MUVANGUA	C106	2024-08-29 17:15	2024-08-29 17:30	527
The South America Map of Orogens	Daniela MATEUS ZABALA	C106	2024-08-29 17:00	2024-08-29 17:15	520
When and how did the Sturtian glaciation begin? insights from the Shennongjia area, northern Yangtze Craton	Yuchong Wang	C106	2024-08-29 17:45	2024-08-29 18:00	540
Palynological variability within the Permian (Changhsingian) Umm Irna Formation (Jordan): implications for biostratigraphy and fluid flow character in alluvial formations	Michael Stephenson	C106	2024-08-29 18:00	2024-08-29 18:15	523
Factors affecting sequence structure and sequence-stratigraphic dynamics	Haoyuan LV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	541
Provenance of Late Precambrian quartzite- schist sequences of the western Central Asian Orogenic Belt	Nadezhda KANYGINA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	542
Vanadium isotope reveals the interval of marine oxygenation during early Cambrian, South China	Hao RAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	544
40Ar/39Ar ages from rocks of the southern part of the Mozambique Belt	Fátima Roberto Chaúque Nampete	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	545
Tectonics and Geodynamics of Antarctica	German LEICHENKOV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	546
Discovering Remnants of the Earliest Continents: 3.4 Ga Basement in the South West Terrane of the Yilgarn Craton and Implications for Archean Geodynamics	Catherine GILL	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	548
Picture Perfect Photogrammetry: mapping the remnants of long-gone glaciers in northern Namibia in unprecedented resolution	Ricarda WOHLSCHLÄGL	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	550
Modern ocean island basalt–like 182W signature in Paleoarchean mafic rocks: A negative μ182W endmember in the lower mantle	Qing-Feng MEI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	551
Sequence biostratigraphy of early Paleogene lignite-shale succession of western India: A case study on an integrated approach to Hydrocarbon Exploration	Shalini PARMAR	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	552
The Cadomian unconformity and the stratigraphy of the Neoproterozoic "Schist-Greywacke Domain" (Portugal)	Artur Abreu SÁ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	554
Zircon U-Pb-Hf isotopic age of gneissic inlier of Aravalli Fold Belt, Rajasthan, India: evidences of Protracted crustal building events from Archean to Mesoproterozoic.	Krishnapriya BASAK	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	555
Lithostratigraphy, structure and metamorphic evolution of Naga Metamorphics, Nagaland, India	NEIPEKREIZO KESIEZIE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	556
In situ Rb–Sr age mapping of micas, feldspars, and clay minerals	DARWINAJI SUBARKAH	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	557
Archean continental crustal growth and reworking of the North China Craton: Constraints from zircon U-Pb age and Hf isotopic composition	Chunrong DIWU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	558
Updating the Cambrian Time Scale: A Bayesian approach	Valentin Jamart	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	559
PROTEROZOIC CARBONATITES IN THE SUL-RIOGRANDENSE SHIELD (SRS), SOUTH BRAZIL	Cimara Francisca MONTEIRO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	561
UNRAVELLING THE ORIGIN OF ALTERNATING FE- AND SI- LAYERS IN IRON FORMATIONS: A MULTISCALE RHEOLOGICAL INVESTIGATION	Elder YOKOYAMA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	563
The Portuguese (PT) version of the "International Chronostratigraphic Chart": a new approach	Manuel João LEMOS DE SOUSA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	564

Title	Presenter	Venue	Start	End	Page
Study on high-precision sequence stratigraphic characteristics and lake level variation trend: A case study of the lower part of the fourth Member of the Paleogene Shahejie Formation (Es4x) in the Niuzhuang Sub-sag	Zhaoxiang CHEN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	566
On the origin of continents: Insights from Archaean Terrains of Arctic Fennoscandia	Jaana HALLA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	568
Provenance analysis of the Tena Formation in the Anzu River, Puyo – Ecuador	Christian WLADIMIR ROMERO CÓNDOR	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	569
Geological and Geomorphological Mapping in Northern Luzon, Philippines using Field Data and Red Relief Image Map (RRIM)	CLOD ANNE VILLALUNA PUNZALAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	570
New data on the stratigraphy of the Middle and Upper Jurassic strata of northeastern Iran	Niki MAJIDIFARD	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	572
T4 Tectonophysics					
S1 Eastern Asia tectonic evolution under the multi-plate convergent geodynamics during late Mesozoic		Session Chair: Scientific Program Committee			
New insight into crustal exhumation induced by granitic intrusion following intracontinental contractional deformation: a possible model for Hohhot thermal upwelling-extensional structure, Inner Mongolia, north China	Yu ZHANG	C107	2024-08-29 14:30	2024-08-29 14:45	574
When did the Mongol-Okhotsk Ocean close?	Zhiyu YI	C107	2024-08-29 14:45	2024-08-29 15:00	576
Extensional Tectonics and North China Craton Destruction — insights from the Magnetic Susceptibility Anisotropy (AMS) of granite and Metamorphic Core Complex	Wei LIN	C107	2024-08-29 15:00	2024-08-29 15:15	577
Decoding the link between magmatic cyclicity and episodic extensional and contractional tectonics: insights from the Late Mesozoic granites of the eastern China	Lingtong MENG	C107	2024-08-29 15:15	2024-08-29 15:30	580
Late Cretaceous rapid uplift and denudation of northern Tibet and its climatic effects	Hao WU	C107	2024-08-29 15:30	2024-08-29 15:45	575
The Central Asian fold belt (CAOB): granite domes of the Erguna Massif as indicator of Mesozoic extension (evidence from the Trans-Baikal geotransect and parametric borehole of 2 600 m depth)	Ivan KUDRIAVTCEV	C107	2024-08-29 15:45	2024-08-29 16:00	578
The Lateral Accretionary Orogenic Process at Pangea's Conveyable Zone: Insights from the Borneo's Oldest Granitoids in Southeast Asia	Shan LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	582
Middle-Late Jurassic crustal shortening in the central–western North China craton in response to multi-plate convergence in the East Asia	Wei SHI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	583
Gondwanan Flood Basalts Linked Seismically to Plume-Induced Lithosphere Instability	Yanan SHI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	584
Late Jurassic true polar event revealed by paleomagnetic study in North China and its implication for regional tectonics and biota evolution in East Asia	PAN ZHAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	585
Cyclical and progressive destruction of the cratonic lithosphere of South China	Yang CHU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	586
Discussion on the Metallogenic Geological Body of the Qixiashan Pb-Zn Polymetallic Deposit in Jiangsu Province, China	Mingchao ZHANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	587
Mesozoic Uplift of the Dabashan and the Micangshan-Hannan Dome in the South Qinling Orogenic Belt determined by analysis of lithospheric flexure	Xiong XIONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	589
S2+S4 Intraplate tectonics and seismicity		Session Chair: Jin-Hyuck CHOI, Taehyung KIM			
The silent and slow active faults of Germany: results from paleoseismological trenching	Klaus REICHERTER	C109	2024-08-28 14:30	2024-08-28 14:45	600
Identification of seismic activity and basin inversion based on soft-sediment deformation structures: An example from SE Korea	Jinhyun Lee	C109	2024-08-28 14:45	2024-08-28 15:00	590
Intracrystalline deformation may explain the recurrence of small-magnitude tremors in an intraplate region- A case study from the Koyna-Warna Seismogenic Region, Western India	PIYAL HALDER	C109	2024-08-28 16:00	2024-08-28 16:15	596
Long-term patterns of paleo-earthquakes influenced by climate change on the Korean Peninsula	Man-Jae KIM	C109	2024-08-28 15:15	2024-08-28 15:30	592
New Constraints on the Active Tectonics of Gulf of Kuşadası, Western Turkey: Insights from a Comprehensive Offshore Survey	Gülsen Ucarkus	C109	2024-08-28 15:30	2024-08-28 15:45	593
Earthquake Geology of the Mogod Fault, Mongolia	Hankyung Bae	C109	2024-08-28 16:15	2024-08-28 16:30	598
Decoding Paleostress Conditions from the Morphology of Quaternary Volcanic Craters along the Western Branch of the East African Rift System: Implications for Volcanic Hazard Assessment	Francois HATEGEKIMANA	C109	2024-08-28 15:45	2024-08-28 16:00	595
Intraplate neotectonics and activity of thrust segment in the Ulsan fault, SE Korea	Kiwoong PARK	C109	2024-08-28 15:00	2024-08-28 15:15	591
Paleoseismic event timing and surface rupture scenarios on the Yangsan Fault, SE Korea	Taehyung KIM	C109	2024-08-28 16:30	2024-08-28 16:45	599

Title	Presenter	Venue	Start	End	Page
The Eastern English Channel (North of France) : Some examples of intraplate tectonics and seismicity	Virginie GAULLIER	C109	2024-08-28 16:45	2024-08-30 17:00	605
The Evaluation and Morphometric analysis of Active Tectonics in Zagros Folded Belt (ZSFB), West of Iran	SAMBIT PRASANAJIT NAIK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	602
Numerical modelling of tectonic stress and deformation of the Andaman Subduction Zone	Radheshyam YADAV	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	604
S3 Deformation processes and texture analysis		Session Chair: Munjae PARK, Sejin JUNG			
A study on petrofabrics of garnet in calc-silicate rocks in the Yeongnam Massif, South Korea	Seokyoung HAN	C107	2024-08-29 16:00	2024-08-29 16:15	607
Preliminary results of the deformation texture of diopside in serpentinite	Jungjin LEE	C107	2024-08-29 16:15	2024-08-29 16:30	608
Seismic anisotropy of slaty rocks: Unveiling the effect of the CPO on seismic properties	Victor CARDENES	C107	2024-08-29 16:30	2024-08-29 16:45	609
Deformation microstructures and seismic anisotropy of Yeoncheon amphibolites in the Imjingang Belt, South Korea	Sejin JUNG	C107	2024-08-29 16:45	2024-08-29 17:00	610
Chlorite dehydration in chlorite peridotite and implications for intermediate-depth earthquakes in subducting slabs	Haemyeong JUNG	C107	2024-08-29 17:00	2024-08-29 17:15	611
Lattice-preferred orientations of glaucophane, zoisite, and epidote in zoisite-epidote blueschist from Río San Juan metamorphic complex, Dominican Republic	Yong PARK	C107	2024-08-29 17:15	2024-08-29 17:30	612
All six typical olivine CPO types discovered in single research area and its seismic implications	Yilun Shao	C107	2024-08-29 17:30	2024-08-29 17:45	614
Differential Stress Affecting Preservation of Intergranular Coesite in UHP Rocks from the Dabie Shan: Ultra-microstructure Insights from TEM	Jinyu ZHENG	C107	2024-08-29 17:45	2024-08-29 18:00	615
Intracrystalline deformation microstructures in natural olivine with implications for stress estimation	Jian MA	C107	2024-08-29 18:00	2024-08-29 18:15	617
PROGRESSIVE STRAIN LOCALIZATION AND FLUID-ASSISTED DEFORMATION IN MANTLE EXHUMATION DURING RIFTING: PETROSTRUCTURAL CONSTRAINTS FROM THE ZABARGAD PERIDOTITES, RED SEA)	Marialine CHARDELIN	C107	2024-08-29 18:15	2024-08-29 18:30	618
Rheological inhomogeneities in the geodinamic structures of the earth' s crust	GENNADY ERMOLAEV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	620
Evolution of Deformation Microstructures and Fluid Inclusions in Peridotite Xenoliths beneath the Rio Grande Rift	Munjae PARK	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	622
Tectonic characteristics and petroleum geological significance of the CiCun fault	Jun YANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	623
Deformation microstructures of blueschists in Alpine Corsica, France, and implications for seismic properties in subducting oceanic crust	Seungsoon CHOI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	624
Petrofabrics and microstructures of phyllite from Geumseongri Formation, South Korea: Implications for seismic anisotropy	Seokyoung HAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	626
Microstructures of deformed granites and calc-silicate rocks in Yeoncheon, South Korea	Sena SIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	627
Lattice-preferred orientation and deformation mechanisms of amphibole in amphibolites from Jenner Headlands, Sonoma County, and Ring Mt., Marin County, California, U.S.A.	Junha KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	628
High-temperature shear initiation of subridge mantle: A microstructural study of peridotites from the Zhongba ophiolite, SW Tibet	ZHANG ZHEN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	629
Crystallographic preferred orientation and seismic anisotropy of minerals in glaucophane schist and eclogite from the Franciscan Complex of Jenner, California	Yoonhae HA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	630
S5 Structure, magmatism and evolution process of oceanic and marginal seas' lithosphere		Session Chair: Weiwei Ding			
[Keynote] Hydrothermal Feedbacks on Tectonics During Magma-Poor Rifting and Start of Oceanic Spreading	Marta PEREZ-GUSSINYE	C107	2024-08-28 08:00	2024-08-28 08:15	639
Deep Structure of the Southeast Asian Curved Subduction System and its Dynamic Process	Weiwei Ding	C107	2024-08-28 08:15	2024-08-28 08:30	631
Influence of Convergence Rate and Subduction Dip Angle on Island-Arc Magma Production	Yongliang BAI	C107	2024-08-28 08:30	2024-08-28 08:45	632
Structure and geodynamics beneath the Indian Ocean inferred from multimode surface wave tomography	Debasis MOHANTY	C107	2024-08-28 08:45	2024-08-28 09:00	634
Continental breakup of Marginal Seas in SE Asia	Jean-Claude RINGENBACH	C107	2024-08-28 09:00	2024-08-28 09:15	636
Detachment fault systems in the Northern South China Sea, insights into 3D tectonic segmentation of rifted margins	Shihao HAO	C107	2024-08-28 09:30	2024-08-28 09:45	638
Characterization of fault systems and implications on structural evolution of the northern Qiongdongnan Basin, South China Sea	Yu QIU	C107	2024-08-28 09:45	2024-08-28 10:00	640
The structure and spreading history of the South China Sea	Zhen SUN	C107	2024-08-28 10:00	2024-08-28 10:15	635
How could density contrast between magmatic rocks and bedrocks affect SDR formations?	Haibin YANG	C107	2024-08-28 10:15	2024-08-28 10:30	633

Title	Presenter	Venue	Start	End	Page
Development of detachment fault system associated with a mature metamorphic more complex: insight from the Kaiping Sag, northern South China Sea rifted margin	Gengbiao LI	C107	2024-08-28 10:30	2024-08-28 10:45	642
Geochemistry and petrogenesis of igneous rocks from the Yap forearc in the western Pacific: Implications for forearc magmatism	Ling CHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	643
The Oceanic crustal structure and the magmatic accretion history of the South China Sea	chenghui ZENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	645
Oceanic crustal structures and characteristics of Syn-Spread Magmatism in the Central basin of the South China Sea	Haixuan SUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	646
Possible Plume-Ridge Interactions during India-Madagascar Break-up	LACHIT SINGH NINGTHOUJAM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	647
New insights to slab interface and crustal structure in Sumatra subduction zone: constraints from novel receiver function analyses	Ling CHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	648
Constraining water flux in the Manila subduction zone with seismic data	Zhenteng WANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	650
Seismic and Gravity Data Analysis of Oceanic Core Complexes in the West Philippine Basin	Yanghui Zhao	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	651
Numerical Model of High-temperature Geothermal Based on Trans-crustal Magmatic System in Eastern Shandong Province	Jie LIU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	983
Rift architecture and evolution controlled by an exhuming and decapitating metamorphic core complex in the Kaiping Sag, northern South China Sea margin	WenDi LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	652
New data on the age of the basement of the Devonian Magnitogorsk island arc (the Southern Urals) according to the results of U-Pb LA-ICP-MS dating of zircons from tuffs of the Irendyk Formation	Ivan SOBOLEV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	653
Synrift and postrift thermal evolution of margins: a re-evaluation of classic models of rifting	Marta PEREZ-GUSSINYE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	655
USE OF MAGNETIC METHODS TO MODEL A GONDWANA SUTURE ZONE IN DEPTH: SOUTHEAST BRAZILIAN CONTINENTAL MARGIN	RAPHAELA LOPES DE ANDRADE SILVA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	656
Intrusive mantle flow induced by thermal heterogeneity during rift propagation	Min-seok JANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	658
S6 Active Tectonics and Earthquake Geology		Session Chair: J. Bruce H. SHYU, Jin-Hyuck CHOI			
[Keynote] Temporal clustering of large earthquakes along the central-eastern sections of the Altyn Tagh Fault, China	Yann KLINGER	C109	2024-08-29 14:40	2024-08-29 15:00	665
Fault Creep Promoted by the Regional Alignment of Fault Networks	Jaeseok LEE	C109	2024-08-29 15:00	2024-08-29 15:15	661
Fossil Earthquakes Preserved on Fossils: New examples from Taiwan	JIH-PAI LIN	C109	2024-08-29 15:15	2024-08-29 15:30	663
Evidence of Surface Rupture on Inherited Fault and its Implications for Intraplate Earthquakes in the Central Yangsan Fault, South Korea.	Sangmin HA	C109	2024-08-29 15:30	2024-08-29 15:45	664
A Study on Seismic Velocity Contrast along the Longitudinal Valley Fault System, Taiwan, Using Fault Zone Head Waves	Tzu-Chi Lin	C109	2024-08-29 15:45	2024-08-29 16:00	666
Persistent crustal CO2 degassing following the 2022 M6.8 Chihshang earthquake sequence, eastern Taiwan	Ching-Chou FU	C109	2024-08-29 16:15	2024-08-29 16:30	667
Tectonic Geomorphology and Paleoseismology of the East Solsona Basin Fault in Northern Luzon, Philippines	Noelynna Ramos	C109	2024-08-29 16:30	2024-08-29 16:45	669
Earthquake rupture features in near-surface regions, Korea	Youngbeom CHEON	C109	2024-08-29 16:45	2024-08-29 17:00	659
Frictional slips on artificial fault planes implicating periodic earthquakes along active tectonic plate boundaries	Insun SONG	C109	2024-08-29 17:00	2024-08-29 17:15	668
On the active faults around Gyeongju, Korea: a possible relationship with the 779 AD Gyeongju Earthquake and the Buddhist temples/pagodas in the Silla Dynasty (57 BC – 935 AD) as a 'Bibo Pungsu (Feng Shui theory)'	Chung-Ryul RYOO	C109	2024-08-29 17:15	2024-08-29 17:30	662
Neotectonic deformation and long-term behavior of Masjed-e Soleyman Dam, Iran	Arash Barjasteh	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	670
Multi-disciplinary active fault mapping in the central Gyeongju, SE Kore	Jinhyun lee	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	671
Aseismic, co-seismic, and post-seismic displacements on the September 2022 Guanshan and Chihshang earthquakes, in eastern Taiwan	Horng-Yue Chen	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	672
The characteristics of the Chihshang segment of the Longitudinal Valley Fault System, eastern Taiwan, assessed by historical aerial photo reconstructions	Tsz Yau Amundsen LAM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	673
Active shortening in the axial portion of the Andes in the northern end of the Chilean-Pampean flat slab triggered by sublithospheric controls	Sarah Ellen THOMAS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	674
Quaternary reactivation and paleo-seismologic records along intrabasinal faults in the Miocene Janggi Basin, SE Korea	Jong-Won Han	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	676
Assessing Quaternary-active footwall splays in the Andean thrust front, Southern Precordillera, Argentina (32° 30' S - 68° 49' W)	Victoria Alvarellos	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	678
Active tectonics of the Yuli Fault in the central Longitudinal Valley area, eastern Taiwan	Yu WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	680
Wedge confinement; a brittle faulting process for the accommodation of active block movements in the interior of continents	Esmaeil SHABANIAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	681

Title	Presenter	Venue	Start	End	Page
A short review on geologic evidence of pre-historical large earthquakes in S. Korea	Jin-Hyuck CHOI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	682
Developing Fault Models for Seismic Hazard Assessment in Slow-Deforming Intraplate Regions: A Case Study of the Yangsan Fault, Korea	Taehyung Kim	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	683
S7 Tectonic evolution of modern and ancient orogens in 4D		Session Chair: Gideon Rosenbaum			
[Keynote] Subduction dynamics and overriding plate deformation	Wouter SCHELLART	C107	2024-08-26 16:00	2024-08-26 16:15	687
Space and time variability of styles of continental shortening: new insights from 3D seismic interpretation in the Jura fold and thrust belt	Miller Zambrano	C107	2024-08-26 16:15	2024-08-26 16:30	684
Along-strike change of erosion and sedimentation in the Longmenshan FTB, SE Tibetan Plateau, evidence from analogue experiments	Bin DENG	C107	2024-08-26 16:30	2024-08-26 16:45	688
Tectonic evolution of the Eastern Central Asian Orogenic Belt	Yongjiang LIU	C107	2024-08-26 16:45	2024-08-26 17:00	685
The formation of the Mongolian Orocline in Central Asia: slab-driven or overriding-plate-driven?	Pengfei Li	C107	2024-08-26 17:00	2024-08-26 17:15	689
Crustal Evolution and Mantle-Crust Interaction in the Paleoarchean: Insights from the Southern São Francisco Paleocontinent	Henrique BRUNO	C107	2024-08-26 17:15	2024-08-26 17:30	692
The Southern Segment of the Paleoproterozoic Minas-Bahia Orogen, SE Brazil: an example of a complete orogenic cycle	Monica Heilbron	C107	2024-08-26 17:30	2024-08-26 17:45	694
The architecture of ancient collapsed orogens: an integrated magnetotelluric-structural-seismic study of Paleoproterozoic Trans-Hudson orogen and its foreland	Sally Pehrsson	C107	2024-08-26 17:45	2024-08-26 18:00	696
Slab Subduction and Pull Link Magmatism at Active and Passive Continental Margins	Li-Qun DAI	C107	2024-08-26 18:00	2024-08-26 18:15	690
Slab segmentation, anomalous arc volcanism, and giant porphyry copper deposits in Indonesia	Gideon Rosenbaum	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	698
Exhumation of the Hogem Batholith, north-central British Columbia, Canada	Ruohong JIAO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	700
Orogenic Evolution and Plate Tectonic Significance of the East African Orogen of Turkana, N. Kenya	Morgan L. BLADES	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	701
Cenozoic uplift of Luxi Uplift and the Qinghai-Tibet Plateau and their geological significance	Fengdi GUO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	703
S8 Subduction-related sedimentary basin evolution and lithospheric dynamics		Session Chair: Zhongxian Zhao, Eun Young LEE			
[Keynote] The structure and breakup mechanism of the South China Sea: the feature of subduction related rifting	Zhen SUN	C107	2024-08-29 08:00	2024-08-29 08:30	704
Tectonic-controlled sedimentary basins in NE Iran	Mohammad Reza SHEIKHOLESLAMI	C107	2024-08-29 09:00	2024-08-29 09:15	705
The evolution of Eastern Paleotethys Ocean on Hainan Island, South China	Dai ZHOU	C107	2024-08-29 08:30	2024-08-29 08:45	706
The Late Cretaceous tectonic evolution of the Southern Central Andes: insights from the Malargüe area (36°S)	Matias BARRIONUEVO	C107	2024-08-29 08:45	2024-08-29 09:00	708
Degree of coupling in 3D multilayer lithospheric buckling: Implications for tectonic environments	Seok-Hyeon DO	C107	2024-08-29 09:15	2024-08-29 09:30	710
Sedimentation and subsidence history of the Gosau Group, Austria: Implications of Late Cretaceous subduction and sea level fluctuations	xinxuan Xiang	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	711
Late Cretaceous Tectonic and Paleogeographic Evolution of the Southern Central Andes: Insights from the Diamante Formation at 34°40'S	Federico Exequiel Martos	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	712
Structural evolution of Mud-intrusive and -extrusive System: Insights from 2D seismic reflection data of Makran Accretionary Wedge	SYED AHSAN HUSSAIN GARDEZI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	714
S9 Deciphering complex plate tectonics from the ocean floor		Session Chair: Jerome Dyment, Hanjin CHOE			
Long-range effects of mid-ocean ridge dynamics on earthquakes, magmatic activities, and mineralization events in plate subduction zones	Qiuming Cheng	C107	2024-08-29 09:30	2024-08-29 09:45	716
Unveiling the Evolution of the West Philippine Basin with Massive High-Resolution Seafloor Mapping Data	HANJIN CHOE	C107	2024-08-29 09:45	2024-08-29 10:00	717
World Digital Magnetic Anomaly Map (WDMAM) version 2.2 released	Jerome DYMENT	C107	2024-08-29 10:00	2024-08-29 10:15	718
Can an extraterrestrial body impact affect plate tectonics? The case of Chicxulub and the Yucatan Basin	Jerome DYMENT	C107	2024-08-29 10:15	2024-08-29 10:30	719
Investigating the Chemical Mechanism for Magnetization Reduction in Subducting Oceanic Crust through Hydrothermal Alteration of Magnetic Minerals	Sunhwa HONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	720
S10+S13 Towards better understanding the origin of intraplate earthquakes in East Asia		Session Chair: Eunseo CHOI, Sungho LEE			
[Keynote] Properties, nature and outlook of intraplate earthquakes in the eastern margin of Eurasian plate around the Korean Peninsula	Tae-Kyung HONG	C107	2024-08-28 14:30	2024-08-28 14:45	725
Inside the Central Cordillera of Colombia: La Línea Tunnel	Jorge GÓMEZ TAPIAS	C107	2024-08-28 14:45	2024-08-28 15:00	721
Understanding postseismic deformation patterns in the Korean Peninsula following the 2011 Tohoku-Oki earthquake: Insights from viscoelastic numerical simulations	Sungho LEE	C107	2024-08-28 15:00	2024-08-28 15:15	723

Title	Presenter	Venue	Start	End	Page
The critically stressed state of the earth's crust and the associated response to anthropogenic impact	Andrian Batugin	C107	2024-08-28 15:15	2024-08-28 15:30	724
Effect of postseismic deformation following Tohoku-Oki earthquake on the East Asian intraplate due to the strength of the East-Sea (Japan Sea).	Hyeon-Seob KIM	C107	2024-08-28 15:30	2024-08-28 15:45	726
Permian magmatism and Triassic and Jurassic metamorphism recorded at the western margin of Gondwana, Colombia	Jorge GÓMEZ TAPIAS	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	727
A review of the retroarc foreland metasediments associated with the Devonian-Mississipian west Patagonian magmatic arc, Argentina	Carlos Jorge Chernicoff	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	728
Newly dated Neoproterozoic-Cambrian Las Pacas Complex at the boundary between the Cuyania and Chilenia terranes, southern Mendoza province, Argentina	Carlos Jorge Chernicoff	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	729
A study on magnetization vector inversion modeling of Dokdo submarine volcanic body	SoonYoung CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	730
Deciphering Fissure Dynamics: Magnetic Fabric Insights into Cretaceous Deccan's Volcanic Phenomena from N-S-T Dyke Swarms	GARIMA SHUKLA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	732
Cenozoic crustal thickness variations and surface uplift in the southeastern Tibetan Plateau: Insights from detrital zircon U-Pb geochronology and trace elements in the Gongga Shan region	Xiaoming SHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	734
Evidence of crustal scale fracture system in Central Indian Precambrian (Bastar) Craton, India: Inference from airborne magnetic data analysis and modelling.	AJIT SINGH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	736
S11 Geology and Tectonics of the Western Pacific Marginal Seas		Session Chair: Scientific Program Committee			
[Keynote] Trench kinematics and the opening of backarc basin	claudio faccenna	C107	2024-08-27 08:00	2024-08-27 08:15	752
ML-based volumetric conversion of 2D seismic sections for comprehensive seismic interpretation	Jun-Woo Lee	C107	2024-08-27 08:15	2024-08-27 08:30	738
Hyper-extended basins controlled by low-angle normal faults in Marginal Seas: 3D structure and tectono-sedimentary evolution	Geoffroy MOHN	C107	2024-08-27 08:30	2024-08-27 08:45	740
Cenozoic tectonic history of SE Korea during the evolution of the East Sea (Japan Sea)	Min-Cheol KIM	C107	2024-08-27 08:45	2024-08-27 09:00	742
Morphodynamic interaction between canyons and fans in a Basin and Range setting: the roles of tectonics, bedrock incision and alluviation	Gary PARKER	C107	2024-08-27 09:00	2024-08-27 09:15	743
Tectonic evolution and depositional environments of the southernmost continental shelf basins of Korea, the northern East China Sea	Seok Hoon YOON	C107	2024-08-27 09:15	2024-08-27 09:30	744
A novel coupled model for rift basin evolution: Integrating tectonics, sea-level cycles, and multiple sediment sources	Wonsuck KIM	C107	2024-08-27 09:30	2024-08-27 09:45	746
Depositional Age and Provenance of the Jeju Basin Sediments Inferred by Detrital Zircon U-Pb Geochronology	Taejin CHOI	C107	2024-08-27 09:45	2024-08-27 10:00	747
Subduction Initiation under the Neotectonic Regime of the Western East Sea (Sea of Japan) Margin	Jae-Hyuk LEE	C107	2024-08-27 10:00	2024-08-27 10:15	748
Characterization of Igneous Bodies around the Jeju Basin, the East China Sea: Igneous Stratigraphy and Tecto-Magmatic Implications	Yun-Hui JE	C107	2024-08-27 10:15	2024-08-27 10:30	750
The Distinctive History of the Attu region of the Western Aleutian Arc in the Western Pacific Region	Suzanne KAY	C107	2024-08-27 10:30	2024-08-27 10:45	751
Subduction Initiation process of a young marginal sea: a case study of the North Sulawesi subduction Zone	Tianyao HAO	C107	2024-08-27 10:45	2024-08-27 11:00	753
Geothermal characterization of the Western Pacific marginal seas	Shaowen LIU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	754
An Analysis of Karst Model and its Controlling Factors of Carbonate Buried Hill: A Case Study from the Weixinan Sag, Beibuwan Basin, South China Sea	Yanying LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	755
The Formation and Evolution of the Central Uplift in the South Yellow Sea Basin and Its Geological Significance for Oil and Gas	zhangjin CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	756
Differential deformation characteristics and genetic mechanisms of the central uplift in the South Yellow Sea Basin,China	Qingxun WU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	758
Geochemistry and U-Pb chronology of Silurian clastic rocks from boreholes in the Yellow Sea, Western Pacific Marginal Seas: Geological data evidence that the Yellow Sea belongs to the Yangtze Block	LI ZHIQIANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	759
Thick-skinned tectonics in southern Ulleung Basin (East Sea) through gravity data analyses	Yoon-Mi KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	760
S12 Deep Earth Exploration and Earth CT		Session Chair: Scientific Program Committee			
Phanerozoic tectonic evolution and mineral system formation in East Asia	Xuanhua CHEN	C107	2024-08-30 13:50	2024-08-30 14:05	761
Adaptive mesh-free approach for gravity inversion	Yan LIU	C107	2024-08-30 14:05	2024-08-30 14:20	762
Multi-scale velocity structures of crustal-mantle beneath South China and its constraint on deep mineralization mechanism	Guoming JIANG	C107	2024-08-30 14:35	2024-08-30 14:50	766
New insights into asthenospheric flow beneath the Qinling Orogenic Belt and adjacent areas revealed by a three-dimensional Magnetotelluric study	Gaofeng YE	C107	2024-08-30 14:50	2024-08-30 15:05	768
The geodynamic process of the eastern Tibetan plateau revealed by a 3D structure extracted by the Wavegradiometry Method	Chuntao LIANG	C107	2024-08-30 15:05	2024-08-30 15:20	771
Intraplate thrust orogeny of the Altai Mountains revealed by deep seismic reflection	Lian-Feng Zhao	C107	2024-08-30 15:20	2024-08-30 15:35	773

Title	Presenter	Venue	Start	End	Page
Three-Dimensional Tomography: Unveiling the Tectonic and Mantle Dynamics Beneath the Mendocino Triple Junction	Ziqiang YANG	C107	2024-08-30 15:35	2024-08-30 15:50	775
Heterogeneous lithospheric mantle: A geophysical perspective	Irina ARTEMIEVA	C107	2024-08-30 15:50	2024-08-30 16:05	763
Cratons are not all that stable!	Hans THYBO	C107	2024-08-30 16:05	2024-08-30 16:20	764
Deep Researches of the North Eastern Eurasia: Russian geotransects – results and perspectives	Ivan KUDRIAVTCEV	C107	2024-08-30 16:20	2024-08-30 16:35	769
Study on the deep geological structure of the southern section of the Kyushu-Palau Ridge based on the combined gravity, magnetic and seismic inversion method	KE QIN	C107	2024-08-30 16:35	2024-08-30 16:50	774
Earth CT: Intergrating Deep Earth Profiles to Make Global Transections via Wide Open Collaboration	Qi ZHOU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	776
Seismic discontinuities in the Australian upper mantle: a Bayesian approach using receiver functions and multimode dispersion of surface waves	Kotaro TARUMI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	778
Three-dimensional thermal-rheological structure of East Asian continental lithosphere	Yujun SUN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	779
Upper-mantle velocity and anisotropy under the Mongol-Baikal region	Hanting WU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	780
Determining three-dimensional Vp/Vs model for the Longmenshan fault system and adjacent areas, Sichuan, China	Junjie HAO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	781
Lithospheric structure beneath the Hoh Xil block in the northern Tibetan Plateau revealed by deep seismic reflection profile	Zhanwu LU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	782
Film formation behavior of a hybrid silicate and its anti-hydration performance under a high-temperature environment	Mingyi Guo	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	783
Double-difference Seismic Tomography Using Variational Inference Method and its Application	Hao YANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	784
T5 Planetary Sciences					
S2+S1 Geological Exploration of Lunar and Martian Terrains		Session Chair: Michael Steven Phillips			
Far-IR spectrometer, MIRORES, for orbital ore prospecting on the Moon	Jakub CIAZELA	M316	2024-08-28 08:00	2024-08-28 08:15	786
Foundations for Lunar Landing Sites: Estimating the Bulk Density of Near-surface Lunar Regolith Through Cone Penetrometer Testing of Simulants	Michael LUCAS	M316	2024-08-28 08:15	2024-08-28 08:30	788
Lunar Dust Removal using a Gecko Roller	Charles Pett	M316	2024-08-28 08:30	2024-08-28 08:45	790
Spectrally Feldspathic Detections on Mars: A Review and New Discoveries	Michael PHILLIPS	M316	2024-08-28 08:45	2024-08-28 09:00	792
Structure, rheology, and evolution of the Martian lithosphere across the crustal dichotomy in and around the Tharsis-Valles Marineris provinces	Ratheesh Kumar RT	M316	2024-08-28 09:00	2024-08-28 09:15	785
Gale crater Mars – 3.7 billion years of Mars history from the Curiosity Mars Rover mission	Horton Newsom	M316	2024-08-28 09:15	2024-08-28 09:30	791
Estimation of Lunar Rock Strength: Integrating Regression Analysis and Machine Learning with Apollo Mission Data	Tae Young KO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	793
Volume estimation of specific types of Martian glaciers which may be related to the paleo-environment of Mars	AKIRA SAWADA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	794
S3+S4 The interiors of the Earth, solar system planets, and exoplanets		Session Chair: Takuo Okuchi, Jinhyuk CHOI			
The >3700 km long Great Dyke of Atla Regio, Venus: the longest traced individual dyke in the solar system	Hafida EL BILALI	M316	2024-08-28 09:30	2024-08-28 09:45	796
A role for iron hydrogenation in the layered redox processes of the post-giant impact Earth	Jinhyuk CHOI	M316	2024-08-28 09:45	2024-08-28 10:00	797
Formation and evolution of the protolunar disk	Razvan CARACAS	M316	2024-08-28 10:00	2024-08-28 10:15	799
Crustal extension due to dyke swarm emplacement: Influence on Venusian surface topography including the formation of annular rims/troughs characteristic of coronae	Richard ERNST	M316	2024-08-28 10:15	2024-08-28 10:30	802
Dyke swarm history and associated plume centres of Anala and Irnini Montes in Central Eistla Regio, Venus	AASTHA MISHRA	M316	2024-08-28 10:30	2024-08-28 11:00	800
In-situ high-pressure and high-temperature study of the Fe-S-O-H system: An implication for the thermal evolution of the Martian core	Jeongmin LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	805
Experimental seismic velocity measurements of chlorite and antigorite using the PE press	Nicholas Backhouse	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	806
Numerical simulation of planetary core formation using FEniCS Project for extending 3D modeling	Kyeong-Min LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	808
S5+S6 Meteorites: Probing the Origins and Evolution of our Solar System		Session Chair: Changkun Park			
Collisional erosion of planets recorded by lithium isotopes	Yingkui XU	M315	2024-08-28 08:00	2024-08-28 08:15	809
Petrochemical and shock heterogeneity in Shergotty achondrite	ARINDAM DUTTA	M315	2024-08-28 08:15	2024-08-28 08:30	810
Aluminium-Magnesium Ages of Evolved Achondrites	Zoltan VACI	M315	2024-08-28 08:30	2024-08-28 08:45	811
Maximizing the Value of Meteorite Data for Future Science	Kerstin Lehnert	M315	2024-08-28 08:45	2024-08-28 09:00	813
Chemical evidence for the melting of alkali feldspar in a lunar meteorite DEW 12007	Hyeong Gyu KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	815
Experimental Method for Measuring Cohesion of Regolith via Electrostatic Lofting	Charles T Pett	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	817
S7+S8 Planetary Habitability: From Extremophiles to Potential Life		Session Chair: Scientific Program Committee			

Title	Presenter	Venue	Start	End	Page
Ore prospecting in planetary analog using remote sensing data	Marta CIAZELA	M315	2024-08-28 09:30	2024-08-28 09:45	819
Iron's Role in Astrobiology: The Significance of Ferrihydrite in Martian Habitability	Adomas VALANTINAS	M315	2024-08-28 09:45	2024-08-28 10:00	822
Development of Early Microbial Communities within Newly Emplaced Lava in Iceland: A 3-Year Fixed-site Time-series Study	Nathan Hadland	M315	2024-08-28 10:00	2024-08-28 10:15	824
Geological evidence reveals a staircase pattern in Earth's rotational deceleration evolution	He HUANG	M315	2024-08-28 10:30	2024-08-28 10:45	820
Astrochronology and cyclostratigraphic analysis of Ordovician-Silurian transition —— Case study from JY11-4 borehole in Yangtze Block, Southern China	Shang YUE	M315	2024-08-28 10:15	2024-08-28 10:30	821
Profiling the lipidome of microbial communities in Icelandic and Azorean lava tubes	Joleen M CSUKA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	826
S9+S10 Comparative Planetary Geology Studies		Session Chair: Scientific Program Committee			
GEOLOGIC MAPPING OF LUNAR PYROCLASTIC DEPOSITS IN SINUS AESTUUM, RIMA BODE, AND MARE VAPORUM	Catherine Weitz	M211	2024-08-28 09:30	2024-08-28 09:45	828
Late Drainage Along Samara Valles, West of Jones Crater, Margaritifer Terra, Mars	John GRANT	M211	2024-08-28 09:45	2024-08-28 10:00	830
Enhanced bedrock weathering on Martian hillslopes with Recurring Slope Lineae (RSL)	Amit MUSHKIN	M211	2024-08-28 10:30	2024-08-28 10:45	831
Open mineral identification from CRISM hyperspectral data using an ensemble of Support Vector Machines and Extreme Value Theory	Sandeepan DHOUNDIYAL	M211	2024-08-28 10:45	2024-08-28 11:00	832
Terrestrial hot spring systems as repositories for biosignatures on Earth and Mars	Federica BARILARO	M211	2024-08-28 10:00	2024-08-28 10:15	834
From Jezero Crater to Nili Planum: Tracing the Subsurface Life Potential on Mars	Adomas VALANTINAS	M211	2024-08-28 10:15	2024-08-28 10:30	835
S12+S11+S13+S14 Impact crater, Lunar Science and Exploration		Session Chair: Jaesoo LIM			
(MAPCIS) Massive Australian Precambrian-Cambrian Impact Structure: evidences supporting confirmation for impact designation	Daniel CONNELLY	M311	2024-08-28 08:00	2024-08-28 08:15	837
Mineralogy and chronology of Ca-phosphates in the lunar meteorite SaU_169	Xiaochao CHE	M311	2024-08-28 08:30	2024-08-28 08:45	838
Light noble gases characteristics in Chang'E-5 lunar soil	Junjie LI	M311	2024-08-28 08:45	2024-08-28 09:00	840
Mapping the Geology of Venus as an Engagement Tool for Undergraduate Planetary Science Research	Katherine Janet Boggs	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	841
Platinum Group Element abundances and Re-Os isotopic composition of melt rock/breccia support the impact origin of the Simlipal structure, Singhbhum Craton, India	AJAY Kumar SINGH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	843
The application of ilmenite Crystal Size Distributions in experimental charges to understand the cooling rates of Apollo 11 basalts	Vanesa Mary C	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	845
Bridging Disciplines: A Feasibility Study on Integrating Mathematics and Geology in Education	Lujia PAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	847
Magnetic Susceptibility Instrument for Magnetically Inhomogeneous Granular Mixtures	Charles T Pett	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	849
COMPLEX MAGMA CHAMBER PROCESSES IN THE MOROKWENG IMPACT MELT SHEET, SOUTH AFRICA	SUMAN MONDAL	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	851
The temperature distribution in the mantle of the Moon based on geophysical data and evolutionary model	Ekaterina KRONROD	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	853
Decoding a complex geological record of the Yilgarn Craton using laterite iron crusts enriched with scandium	Daria LONGLEY	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	854
T6 Metamorphism					
S1 Application of thermodynamic modelling in understanding the process of metamorphism		Session Chair: Scientific Program Committee			
[Keynote] Phase equilibria computations in Metamorphic Petrology-Applications and limitations	Somnath Dasgupta	M315	2024-08-27 08:00	2024-08-27 08:15	865
Paleoproterozoic (2.01 Ga) high-pressure granulite facies metamorphism in the Central Zone of the Limpopo Belt (Eastern Botswana/South Africa): geodynamic implications	Reiner KLEMD	M315	2024-08-27 08:15	2024-08-27 08:30	856
Kyanite trace element zoning as a tool for gaining insights into the petrological evolution of migmatites	Sara Nerone	M315	2024-08-27 08:30	2024-08-27 08:45	858
H2O content variation in the metamorphic evolution of shear zones: a case from the Dora-Maira Massif (Western Alps)	Sara Nerone	M315	2024-08-27 08:45	2024-08-27 09:00	859
Indian Scientific Expedition to Bharati research base for constraining Metamorphic Evolution of Larsemann Hills, East Antarctica	ROSAN MALLIK	M315	2024-08-27 09:00	2024-08-27 09:15	863
Pre-Himalayan Metamorphism in the Lesser Himachal Himalaya: Insights from P-T pseudosection, U-Pb dating of zircon and monazite, and Sm-Nd garnet isochron	HIFZURRAHMAN -	M315	2024-08-27 09:15	2024-08-27 09:30	860
Petrogenesis of Maneswar Complex, Rengali Province, India: Implications for tectono-metamorphic evolution along craton-mobile belt margin	PRIYA PACHAURI	M315	2024-08-27 09:30	2024-08-27 09:45	861

Title	Presenter	Venue	Start	End	Page
Comparing qualitative and quantitative isopleth thermobarometry based on garnet composition	Sara Nerone	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	866
Phase equilibria and advanced thermobarometric modellings of Paleoproterozoic metapelites of NW Himalaya, India: Implication for its linkage with the Aravalli Supergroup	BIRAJA PRASAD DAS	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	867
PHASE EQUILIBRIA MODELLING AND PETROLOGY OF PELITIC GRANULITES IN SOUTHEASTERN NIGERIAN BASEMENT COMPLEX: INSIGHTS INTO THE EVOLUTION OF THE TRANS SAHARAN OROGENIC BELT.	Ifeoma Chinwendu AGHAEBITA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	868
Metamorphic P-T paths and timing of garnet-mica schists from the Mianlüe Tectonic Zone: Insight into the early Mesozoic collisional thickening of the South Qinling orogen, Central China	Sang Wan PAK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	869
P-T pseudosection and garnet diffusion modeling of phengite eclogite from Yuka terrane, North Qaidam	Rong-GuoHU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	870
S2 Subduction zone fluids: mineralogical and geochemical effects and geodynamic consequences		Session Chair: Scientific Program Committee			
[Keynote] Formation of abiotic H2 and CH4 in subduction zones	Renbiao TAO	M315	2024-08-27 14:30	2024-08-27 14:45	889
The processes of serpentinization in subduction zones: Reaction rates and hydrogen (H2) generation	Ruifang HUANG	M315	2024-08-27 14:45	2024-08-27 15:00	876
Fluid inclusions of ophicarbonates in Oman and Western Alps ophiolite and carbonation experiments of mantle minerals	Tatsu KAWAMOTO	M315	2024-08-27 15:00	2024-08-27 15:15	882
Hydrogen solubility of stishovite provides insights into water transportation to the deep Earth	Lei Kang	M315	2024-08-27 15:15	2024-08-27 15:30	878
The fate of methane in subduction zone fluids	Lijuan ZHANG	M315	2024-08-27 15:30	2024-08-27 15:45	888
The contribution of serpentinite to crust-mantle interaction and arc magma formation in subduction zones	Yi-Xiang CHEN	M315	2024-08-27 15:45	2024-08-27 16:00	872
Fluid-mediated Cu and Zn isotopic fractionation in subduction zones: Constraints from high pressure veins within eclogites in the Dabie Orogen	Jian HUANG	M315	2024-08-27 16:15	2024-08-27 16:30	885
Halogen cycling at the slab-mantle interface: constraints from metabasites from SW Tianshan, China	Zheng-Hua Pan	M315	2024-08-27 16:30	2024-08-27 16:45	884
Supercritical fluids in subduction zones and their geochemical effects	Ren-Xu Chen	M315	2024-08-27 16:45	2024-08-27 17:00	874
Magnesium isotope constraints on the role of recycled carbonate-rich sediments in the formation of ultrapotassic magmatic rocks at a continental arc setting	chen yu	M315	2024-08-27 17:00	2024-08-27 17:15	873
Imprints of eclogite-facies metasomatism in the North Balkhash ophiolite zone (Central Kazakhstan, west Central Asian Orogenic Belt)	Anfisa SKOBLENKO	M315	2024-08-27 17:15	2024-08-27 17:30	880
"Detrital" zircons in eclogite: their origin and implications for mass transfer	Taehwan KIM	M315	2024-08-27 17:30	2024-08-27 17:45	886
Subducted serpentinite contributes to the formation of arc lavas with heavy Mo isotopic compositions	Fu-Qiang DAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	891
Deciphering the relative timing of deformation, recrystallization and fluid infiltration in the Dalrymple Amphibolite: Implications to the slab-mantle wedge interface	Gabriel Theophilus Vinalay VALERA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	892
Contributions of serpentinizing fluids to the low δ^{26}Mg isotopes of subduction zone fluids: Evidence from jadeitites and jadeite-rich rocks from the Rio San Juan complex, the Northern Dominican Republic	KUN CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	894
Petrological and geochemical diversities of pyroxene pseudomorphs in ultramafic rocks originated from the mantle wedges: Insights into elemental transfer in slab-mantle interfaces	Takumi Wani	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	896
The genesis of metabasic rocks in the Yadong region of the Himalayan orogenic belt	XIN DONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	898
Serpentinization and deserpentinization of the mantle wedge at a convergent plate margin	ZHUANGZHUANG YIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	900
Hydration of the deep mantle by slab-derived fluids: insights from arc-type hornblendites of eastern Arunachal Himalaya, NE India	Amrita DUTT	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	902
Fluid flow and isotopic inheritance in the subducted eclogitic crust recorded by in-situ Rb-Sr isotopes (North Balkhash ophiolite zone, Central Kazakhstan)	Sergei SKUZOVATOV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	903
Mineral assemblage and temperature estimates of continent-derived metapelites and metapsammites in Sibuyan Island, Romblon, Philippines	John Kenneth Beran BADILLO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	905
Tectono-metamorphic events in the west central Philippines: Insights from the metamafic rocks of Tablas Island, Romblon	Andrew Exequiel Sanchez TABILOG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	907
Metamorphic complexes of western and central Mongolia	ERDENEJARGAL CHOINDONJAMTS	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	908
Geochemical evidence from coesite-bearing jadeite quartzites for large-scale flow of metamorphic fluids in a continental subduction channel	Xiao-Ying GAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	909
The effect of argillization and opalization on the properties of andesites and basaltic andesites on the thermal fields of the Kamchatka Peninsula	Ilya BOLSHAKOV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	910
Tracing the incipient melting P-T-t conditions of felsic gneiss in South Altyn Tagh: implications on the exhumation of deep subducted slabs	Yongsheng GAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	912

Title	Presenter	Venue	Start	End	Page
The structure and transport properties of diopside supercritical fluid from machine learning potential	DONG WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	914
Subducted metasedimentary veneer impedes slab–arc carbon recycling	Jilei Li	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	915
Vein-induced carbonatitic metasomatism of eclogites in subduction zones: implications for carbon cycling and mantle isotopic heterogeneity	Weiqiang Ll	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	916
The mechanism for heavy Cr isotopes in some serpentinites and its implications	Ji SHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	917
Origin of fluid beneath the Noto peninsula, Central Japan: Stability of Lawsonite eclogite	Kazuaki OKAMOTO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	918
Four alkaline shifts of metasomatic reactions by a texture analysis for a garnet amphibolite at 1GPa and ~700°C in Oeyama Ophiolite, Japan	Riichi AKAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	919
S3 General Topics		Session Chair: Scientific Program Committee			
Carboniferous, not Paleoproterozoic, eclogite-facies metamorphism in the northern North China Craton as revealed by in-situ garnet Lu-Hf and U-Pb geochronology	YAOQI YAN	M315	2024-08-26 16:00	2024-08-26 16:15	922
Low-pressure, high-temperature metamorphism in the central Mary Kathleen Fold Belt, north-eastern Australia: Tracking an anticlockwise P-T-t path by linking phase equilibrium modelling, microstructures, and in situ geochronology	Juergen REINHARDT	M315	2024-08-26 16:15	2024-08-26 16:30	924
Metamorphic age and potential heat source for the Buchan-type metamorphism in the Wilson Terrane, northern Victoria Land, Antarctica	Yoonsup KIM	M315	2024-08-26 16:30	2024-08-26 16:45	929
Pressure calibration of natural-quartz Raman spectra variation under hydrostatic condition	Kazuaki OKAMOTO	M315	2024-08-26 16:45	2024-08-26 17:00	930
Protracted crustal evolution of the Nigerian Basement Complex: Insights from Neoproterozoic tectono-magmatic overprint and protolith source analysis.	Chinedu Ibe	M315	2024-08-26 17:00	2024-08-26 17:15	921
Synchronous Paleocene (ca. 60 Ma) India-Asia collision indicated by high-pressure metamorphic rocks in the Himalaya	Yanling ZHANG	M315	2024-08-26 17:15	2024-08-26 17:30	926
Exsolution textures of Antiperthite and Mesoperthite in the Zhengjiapo BIF, Changyi Metallogenic Belt, North China Craton: evidence of UHT Metamorphic Overprint	Yanrong CHEN	M315	2024-08-26 17:30	2024-08-26 17:45	928
Fluid-fluxed anatexis of Paleoproterozoic granitic gneiss in the Yeongnam Massif, Korea	Yuyoung LEE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	932
Middle Permian high-pressure rocks preserved in the Southern Beishan Orogenic Belt, NW China: metamorphic evolution and tectonic implication	Wenxuan Li	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	934
Experimental evidence for the exsolution of kyanite from Al-bearing stishovite: Implications for ultra-deep subduction/exhumation of continental crust	Liang Liu	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	935
TIN ORE FORMATIONS OF ZIRABULAK-ZIAETDIN REGION OF UZBEKISTAN	Farrux Raxmatullayev RAXMATULLAYEV	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	937
The metamorphic events registered in the Santander Massif (Colombia)	Luis C.MANTILLA F.	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	938
METAMORPHIC EVOLUTION OF THE UBENDIAN BELT IN NORTHERN MALAWI	Ruth MUMBA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	940
Crustal Thermal transitions and the Rise of the Tibetan Plateau: From Amphibolite to Ultrahigh-Temperature Granulite Facies Crust since the Miocene	XIU-ZHENG ZHANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	941
T7 Volcanology					
S1 Large Igneous Provinces in Space and Time		Session Chair: Hafida EL BILALI			
[Keynote] Dyke swarms of the Indian Shield in space and time: characterizing Large Igneous Provinces, their plumbing system and likely mineral systems	Rajesh Kumar SRIVASTAVA	M316	2024-08-29 14:30	2024-08-29 15:00	947
Record of Archean Large Igneous Provinces (LIPs) and their mafic dyke swarms	Richard Everett ERNST	M316	2024-08-29 15:00	2024-08-29 15:15	954
Neoproterozoic (ca. 830 Ma) carbonatite dykes from Qianlishan in the western North China Craton and their tectonic and metallogenic	Shuan-Hong ZHANG	M316	2024-08-29 15:15	2024-08-29 15:30	944
A new ca. 2.49-2.46 Ga Silicic Large Igneous Province (SLIP) event in the Bastar craton, India	Amiya Kumar SAMAL	M316	2024-08-29 15:30	2024-08-29 15:45	946
Deciphering the Emplacement Mechanism of Paleoproterozoic Mafic Dyke Swarms in the Dharwar Craton: Insights from AMS and Fracture Analyses	SRINJOY DATTA	M316	2024-08-29 15:45	2024-08-29 16:00	945
A comprehensive geochemical study on mafic dyke swarms from the central-western Bastar craton, India, and their link with different Paleoproterozoic large igneous provinces of the Indian Shield	Ankur ASHUTOSH	M316	2024-08-29 16:00	2024-08-29 16:15	955
The Midcontinent Rift System LIP initiated passively — Evidence from diverse mantle source contributions during early rift development	Pete HOLLINGS	M316	2024-08-29 16:30	2024-08-29 16:45	949
Links between plume-generated LIPs and new ocean formation through	Hafida EL BILALI	M316	2024-08-29 16:45	2024-08-29 17:00	951
The Karoo large igneous province contains diamondiferous lamproites	Sebastian TAPPE	M316	2024-08-29 17:00	2024-08-29 17:15	959

Title	Presenter	Venue	Start	End	Page
Early Aptian volcanism of the Kerguelen LIP and its implications for the evolution of the proto-Indian Ocean	Eun Young Lee	M316	2024-08-29 17:15	2024-08-29 17:30	942
The effective elastic thickness of lithosphere for continental large igneous provinces	Qin WANG	M316	2024-08-29 17:30	2024-08-29 17:45	952
Revealing 2.4 LIP in the Belomorian province, Fennoscandian Shield: U-Pb ID-TIMS studies of baddeleyite and baddeleyite-zircon aggregates	Maria Alexandrovna SUKHANOVA	M316	2024-08-29 17:45	2024-08-29 18:00	957
Dyke swarms map of the Indian Shield on 1:25,00,000 scale	Amiya Kumar SAMAL	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	960
Petrological study of the Agulhas Plateau in the Southwest Indian Ocean: Results from core samples drilled during IODP Expedition 392	Kouki MORI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	961
First Report of Carbonate Antecrysts in the Newania Carbonatite, Rajasthan, India: Implications for Carbonatite Petrogenesis	Amritpaul SINGH	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	963
The areal extent of the Qiangtang-Panjal large igneous province	Wei Dan	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	965
Permian-Triassic silicic volcanic province of the West Siberian basin: Evidence for the temporal and genetic relationship with the Siberian Traps	Anton LATYSHEV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	966
Multiple mantle components for alkaline lavas of the Tuli basin, Karoo LIP	Osvaldo González-Maurel	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	967
Late Permian basalts in the eastern part of the Emeishan Large Igneous Province, SW China: Implications for plume–lithosphere interaction	Wenmin HUANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	969
The Late Mesozoic Volcanic Events and Metallogenic Basin Dynamics Mechanism in Eastern Shandong and Adjacent Seas	YanZHANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	956
S2+S5 Cretaceous Volcanism: Global Distribution Bearing on Tectonics of Continents and Oceanic Regions, K-T Boundary and Major Extinction		Session Chair: Scientific Program Committee			
Evidence of prolonged Aptian-Santonian magmatic pulses in the Indian Shield linked with the Marion mantle plume and its role in the breakup of India–Madagascar	Rajesh Kumar SRIVASTAVA	M316	2024-08-29 08:00	2024-08-29 08:15	971
Paleoenvironmental Constraints on Pleistocene Ice Sheets Informed by Glacio-Volcanic Deposits in Northeast Iceland	Cameron Essex	M316	2024-08-29 08:15	2024-08-29 08:30	973
Neoarchean volcanism in the Western Dharwar Craton, India: Petrology, Geochemistry and Tectonic Significance of BADR volcanics from Shimoga basin	Arpita KARMAKAR	M316	2024-08-29 08:30	2024-08-29 08:45	975
Recognition of Hidden Effusive Centers from the Emanating Pattern of Lava Tube and Channels in Deccan Volcanic Province of Western India	ANSHUMAN MISRA	M316	2024-08-29 09:00	2024-08-29 09:15	974
Development of New Concepts in Cretaceous Volcanism during Last Fifty Years in Peninsular India	K S MISRA	M316	2024-08-29 09:15	2024-08-29 09:30	977
Recent Evidence of the Evolution of Pleistocene Volcanism in the Northwestern End of the Central Volcanic Cordillera of Costa Rica, Central America.	Ana Sofia HUAPAYA R.P.	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	979
Block-and-ash flows deposit from 2015 at Volcán de Colima (Mexico): Textural and granulometric characterization as a tool in determining the dynamics and interaction with topography	Laura Fabiola HERNANDEZ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	981
Post-2008 Eruption Volcanic Activities of Cerro Azul Volcano in the Galá pagos Archipelago Estimated Using Time-series InSAR	Seohyeon Kim	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	982
Temporal distribution of the Plagioclase Feldspars in ~1200 m thick lava flow sequence from Deccan traps borehole, Western Deccan Province	Shubham Bharat WAGHMARE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	984
Plio-Pleistocene rear-arc magmatic belt in the Southern Central Andes: the Varvarco Volcanic Field	Sofía Iannelli	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	985
Geochemistry of the Volcanic Rocks of the Central Northeast Foothills of the Tilarán Volcanic Arc, Costa Rica	Martin Rojas Barrantes	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	987
Records of lava-ice interactions during the Pleistocene in the Chiles volcano, Colombia-Ecuador border	CAMILA MARTINEZ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	989
The Late Cretaceous explosive volcanism products in Bolnisi district and associated mineralization: Lesser Caucasus, Georgia	Nino POPKHADZE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	991
Geochemical and geochronological evolution of mafic-felsic volcanic rocks prior to the collision of India and Eurasia: Evidence from the northwestern Ladakh Himalaya, India.	Nongmaithem Lakhan SINGH	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	993
Radiogenic Sr, Nd, Hf and Pb isotope characteristics of Pumice from the Andaman Sea	Prabala Bhaskara RAMA MURTY	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	994
Tertiary and quaternary volcanism of the western part of Senegal: State of research and prospects	Raymond SAGNA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	995
S3 Volcano Geology: role of field work on modern Volcanology		Session Chair: Gianluca Groppelli			
GEOLOGIC MAP OF THE PLEISTOCENE VOLCANO OF MONTE AMIATA (SOUTHERN TUSCANY, ITALY)	Claudia Principe	M316	2024-08-29 09:30	2024-08-29 09:45	1000
Updated post 3 ka BP volcano-stratigraphy of Ulleungdo volcano, South Korea: insights into the Holocene post-caldera eruptions	Ho-Jun AHN	M316	2024-08-29 09:45	2024-08-29 10:00	1001

Title	Presenter	Venue	Start	End	Page
Monitoring magma chamber processes at silicic volcanoes through single zircon mineral chemistry and U-Pb ages in the Sabga Volcanic Complex, Cameroon Volcanic Line	Edith Etakah TIBANG	M316	2024-08-29 10:30	2024-08-29 10:45	997
Preliminary Study of Magma Mixing/Mingling in Pleistocene Volcanic Rocks of the Rakiraki Area, Viti Levu, Fiji	Kamal REGMI	M316	2024-08-29 10:15	2024-08-29 10:30	998
Carbon Isotope Fractionation in Silicate Melt: Window into Carbon	Hyunjoo LEE	M316	2024-08-29 10:45	2024-08-29 11:00	999
Volcano-tectonic activity of Pantelleria Island (Italy) and relationship with the Green Tuff emplacement	Gianluca Groppelli	M316	2024-08-29 10:00	2024-08-29 10:15	1002
Structure and composition of the Late Miocene Goderdzi Volcanic Complex, Lesser Caucasus, Georgia: implication for resurgent caldera formation	Miriani MAKADZE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1003
Correlation of proximal and distal deposits of a caldera-forming eruption based on the variation of juvenile materials: A case study of Toya Volcano, southwestern Hokkaido, Japan	Mitsuhiro Nakagawa	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1005
S4 Volcanism on the Korean Peninsula		Session Chair: Jinhuem PARK			
[Keynote] Hydrovolcanic activity in relation to Quaternary sea levels in Jeju Island, Korea	Young Kwan Sohn	M316	2024-08-30 08:00	2024-08-30 08:15	1008
Morphological analysis of volcanic cones and its implication to Quaternary tectonics of the Jeju Island (South Korea)	Francois HATEGEKIMANA	M316	2024-08-30 08:15	2024-08-30 08:30	1007
Dualistic Bubble Formation in Explosive Silicic Volcanism of Baekdusan	Gi-Bom KIM	M316	2024-08-30 09:15	2024-08-30 09:30	1013
Mantle degassing in South Korea	Hyunwoo LEE	M316	2024-08-30 09:00	2024-08-30 09:15	1012
Triggering of rapid ascent of magma and explosive eruption: The case for the Cretaceous Sinsudo Tuff in the Gyeongsang Basin, Korea	Yong-Un CHAE	M316	2024-08-30 08:30	2024-08-30 08:45	1009
Reconsideration of the magma plumbing system of the Suwolbong tuff ring, Jeju Island, Korea based on rigorous microscopic analysis	Sun Young GO	M316	2024-08-30 08:45	2024-08-30 09:00	1011
Evidence for an upper crustal melt lens beneath Baekdu/Changbaishan Volcano	James HAMMOND	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1014
Evidence for a localised upwelling beneath Baekdu/Changbaishan from seismic imaging and anisotropy	James HAMMOND	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1015
Eruptive and Emplacement Processes of the Namseongri Tuff, southern Jeju Island, Korea	Sunghyun KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1016
A brief introduction of paleomagnetic and rock-magnetic applications for volcanological research in the Korean Peninsula	Hyeon-Seon AHN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1018
Variation of Eu isotope ratio in basaltic rocks in Jeju Island, Ulleung Island, Baekdu Mountain in Korea	Seung-gu LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1019
Three-dimensional resistivity structure of Nari Caldera on Ulleung Island, Korea.	Kiyeon KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1017
T8 Petrology					
S1 Architecture and Thermal Structure of Translithospheric Magmatic Systems		Session Chair: Georg Zellmer			
[Keynote] Crystal Size Distributions (CSDs) in lava samples: a case study on Ruapehu volcano, Southern Taupo Volcanic Zone (STVZ), New Zealand.	Silvia Catalina MORENO ALFONSO	M216	2024-08-28 16:00	2024-08-28 16:15	1022
Plutonic Nature of a Transcrustal Magmatic System: Evidence from Ultrahigh Resolution Sr-Disequilibria in Plagioclase Microantecrysts from the Southern Taupo Volcanic Zone, New Zealand	Georg ZELLMER	M216	2024-08-28 16:15	2024-08-28 16:30	1021
Intense fractional crystallization dominated by amphibole in continental arc: A highly efficient way to generate felsic continental crust	JING RAN	M216	2024-08-28 16:30	2024-08-28 16:45	1023
Current understanding of lithospheric mantle evolution beneath Peninsular India	Sebastian Tappe	M216	2024-08-28 16:45	2024-08-28 17:00	1025
The role of lithospheric mantle in the formation of Earth's crust, gold and REE mineralization	Shanshan Li	M216	2024-08-28 17:00	2024-08-28 17:15	1027
Using mineral records to unravel magmatic roots beneath sibling volcanoes: A case study at Middle Sister and South Sister volcanoes, Oregon Cascades, USA	May Sas	M216	2024-08-28 17:15	2024-08-28 17:30	1029
Multi-component Magmas of Middle Sister and South Sister in the Three Sisters (Klah Klahnee) Volcanic Complex, Oregon Cascades, USA	May Sas	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1031
Petrologic study of the youngest stage lavas of Zao Volcano, NE Japan	Kanako OKI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1033
Maturation of continental arc crust via mush remobilization during magmatic flare-up	Long CHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1035
S2 Granitoids and their enclaves		Session Chair: Scientific Program Committee			
[Keynote] Petrogenesis of episodic volcanic-intrusive rocks in SE China: crystal-melt segregation and magma mixing	Xisheng XU	M216	2024-08-27 14:30	2024-08-27 14:45	1037
Genesis and Evolution of Zoned Magmatic Enclaves in Cretaceous Granitoid: A Case Study from Taejongdae, Busan	Mohammed S. M. Adam	M216	2024-08-27 14:45	2024-08-27 15:00	1036
Mafic magmatic enclaves in Zao Volcano Stage III products, NE Japan: Evidence of conversion of magma feeding system	Masao Ban	M216	2024-08-27 15:00	2024-08-27 15:15	1039
Variscan magmatism with linkage to slab-breakoff? Implication from age data and mineralogy in the Western Carpathians granitic rocks	igor Broska	M216	2024-08-27 15:15	2024-08-27 15:30	1040

Title	Presenter	Venue	Start	End	Page
Origin and evolution of Fe-Ti oxides in leucogranites of Muglib and Pangong regions of Ladakh Trans-Himalaya, India: Insights from textural and chemical features of manganoan-ilmenite and re-equilibrated biotite	Ravi Ranjan Kumar	M216	2024-08-27 15:30	2024-08-27 15:45	1042
Mafic-felsic magma interaction of granitoids and microgranular enclaves in Lohit Plutonic Complex, Arunachal Trans-Himalaya, Northeast India: constraint from field, petrography, mineralogy, geochemistry and U-Pb SHRIMP chronology.	DIEZENEINO MEYASE	M216	2024-08-27 15:45	2024-08-27 16:00	1044
Petrogenesis of Precambrian granitic suites around Ropp Complex: Constraints from zircon U-Pb-Lu-Hf Isotopes, mineral chemistry, and whole-rock geochemistry	Kayode Abdulgafar AMUDA	M216	2024-08-27 16:15	2024-08-27 16:30	1046
Geochemistry, zircon U-Pb geochronology, and Lu-Hf-O isotopes of Paleoproterozoic granite gneisses from Askot-Chiplakot klippe, Kumaun Lesser Himalaya, India: Insight into petrogenesis and evolution of north Indian continental lithosphere	Kapil Singh PANWAR	M216	2024-08-27 16:30	2024-08-27 16:45	1050
Magmatic evolution and geochronology of Mesoproterozoic A-type Darsi granite pluton from Nellore Schist Belt, Southeast India	NARSHIMHA CHINTHAPALLY	M216	2024-08-27 16:45	2024-08-27 17:00	1038
Microgranular enclaves in granitoids are products of mafic to hybrid magma globules mingled and undercooled into partly crystalline host granitoids: Distinct field and microstructural evidences from calc-alkaline granitoid complexes	Santosh KUMAR	M216	2024-08-27 17:00	2024-08-27 17:15	1048
Boundary issue of the Cretaceous granitoid realm in between the Karakoram terrane and the Ladakh magmatic arc along Shyok Suture Zone, Ladakh Trans-Himalaya, India	SITA BORA	M216	2024-08-27 17:15	2024-08-27 17:30	1052
***Geochemical signature of Tinkoto, Tiguida, Koulountou and Dioudioukounkou plutonic masses of the transitional zone between volcanic belt / Dialé basin (Kedougou-Kenieba Inlier South-Est Senegal/West Africa Craton*)**	MAME CODOU NDIAYE	M216	2024-08-27 17:30	2024-08-27 17:45	1053
Genesis of tonalite-granodiorite batholith during subduction to accretion period of the Altai orogen (NW China) and its implications for continental crustal growth	Jianjun ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1054
Silicic microgranular enclaves from the Port Mouton pluton of the Northern Appalachians: implications for the development of the peripheral plutons of the Meguma terrane	Greg Gregory SHELLNUTT	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1055
Geo-characterization of Late Cretaceous mafic microgranular enclaves and host granites: A case study in the Eonyang granite, South Korea	Hui Je JO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1056
Apatite geochemical indicators for magma mixing and fractional crystallization	BaoQuan ZHOU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1057
Early Cretaceous high-δ56Fe rhyolites in central Tibetan plateau: Insights into genesis of A-type magmas	Lu-Lu HAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1059
Early Cretaceous fayalite- and ferrosilite-bearing rhyolitic porphyries and associated biotite-bearing rhyolitic porphyries from the Baishuizhai area, South China: high-temperature crustal melting and magmatic evolution	Xiao LIU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1060
Late Mesozoic high Ba-Sr granitoid in the Xiao Qinling area of Eastern Qinling Orogen, Central China: Petrogenesis and tectonic setting	Chengli ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1061
The extensional tectonic environment within the Urumieh-Dokhtar magmatic belt, NW Iran	REZA MONSEF	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1062
Granitoids of the north of the Urals: U-Pb geochronology (SIMS, LA-ICP-MS, ID TIMS) and isotope geochemical (OZrn, Sm-Ndwr, Lu-HfZrn) characteristics	Oksana Vladimirovna UDORATINA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1063
Formation and tectonic implication of the late Mesozoic Yunmengshan batholith, North China Craton: new constraints from zircon Hf-O isotopes and apatite geochemistry	Jin-Feng SUN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1065
Tectonic understanding of Syenites and Quartz Syenites from Peralimala and Angadimogar plutons, Kerala, India	SAI KRISHNA PRIYA VALLURI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1066
A Method for Calculating Magma Oxygen Fugacity with Uraninite in Granites	Jian GUO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1068
Petrogenesis of mafic enclaves hosted in the Zouzan pluton, Eastern Iran: Insight from the U-Pb zircon geochronology, whole-rock Nd-Sr isotopes, and elemental geochemistry of amphibole and apatite	Santosh KUMAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1070
An amphibolitic source for "adakitic" I-type plutons in continental collision zones	Qiwei LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1072
S3 Crust-Mantle interactions through time and the role of fluids		Session Chair: Sarajit Sensarma			
[Keynote] The Panjal Traps: a synthesis	Greg Gregory SHELLNUTT	M216	2024-08-27 08:00	2024-08-27 08:15	1090
Petrological and geochemical characteristics of the mafic-ultramafic complexes in the Bhavani Shear Zone, South India: implications for crustal evolution.	ABEENA PV	M216	2024-08-27 08:15	2024-08-27 08:30	1073

Title	Presenter	Venue	Start	End	Page
Geochemical characteristics of exsolved deep crustal aqueous fluid in a granitic system: Insights from the quartz reefs in the Bundelkhand craton, India	DIVYANSHI SHUKLA	M216	2024-08-27 08:30	2024-08-27 08:45	1075
Intra-volcanic chain B isotope variations: a case study from the Chilean Central Andes	Osvaldo González-Maurel	M216	2024-08-27 08:45	2024-08-27 09:00	1077
The ~2.5 Ga peraluminous monzo-granite (north-central India) with superchondritic Zr/Hf and OIB-like Nb/Ta: constraints for role of mantle fluid in crustal evolution and crust-mantle interactions	Sarajit Sensarma	M216	2024-08-27 09:00	2024-08-27 09:15	1078
Carbon-sulfur relationships in magmatic sulfide deposits: Implications for metal transfer between the mantle and crust	Shelby CLARK	M216	2024-08-27 09:15	2024-08-27 09:30	1080
Whole rock geochemistry and isotopic constraints on the mafic-ultramafic rocks of the Madawara Igneous Complex, Bundelkhand Craton (central	Abhishek Kumar PANDEY	M216	2024-08-27 09:30	2024-08-27 09:45	1084
Formation of amphibole rich selvege in high P mafic granulite and its relation with the regional hydration of CGGC	Somdipta CHATTERJEE	M216	2024-08-27 09:45	2024-08-27 10:00	1082
Melt inclusions study on Chamundi granite from southern India: Entrapment conditions and compositions	MOHD AQIB	M216	2024-08-27 10:00	2024-08-27 10:15	1088
PETROGENESIS OF MIGMATITES AND LEUCOGRANITE FROM MAIN CENTRAL THRUST ZONE IN AND AROUND MUNSIARI, KUMAUN HIGHER HIMALAYA	CHITRA JOSHI	M216	2024-08-27 10:15	2024-08-27 10:30	1086
New occurrence of carbonatite in the Kudakkal area of Pakkanadu-Mulakkadu Alkaline Complex, Tamilnadu, Southern India.	RAJENDRA PRASAD KANCHI	M216	2024-08-27 10:30	2024-08-27 10:45	1087
Molybdenum isotopes in intraplate basalts record slab-mantle interactions in Earth's deep mantle	WEI FANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1091
Geochemical characterization of Jonnagiri greenstone belt of eastern Dharwar craton, India: Insight into the crustal evolution of Jonnagiri greenstone terrane.	Saumyodeep DAS	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1092
Subduction of an oceanic plateau and its effect on magmatism through the analysis of melt inclusions: The case of the Hikurangi plateau subduction in the Kermadec arc	Raimundo Brahm	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1094
THE USE OF AEROHYPERSPECT DATA FOR THE DETECTION OF HYDROTHERMAL-METASOMATIC ROCKS AS INDICATORS OF SOLID MINERALS Kirsanov A.A. Lipiyainen K.L., Smirnov M.Yu., Kirsanov G.A., Khimchenko P.V., Tkachenko M.A. (Karpinsky Institute, St. Petersburg, RUSSIA)	Aleksaandr Andreevich KIRSANOV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1095
S4 Oceanic lithosphere evolution: crust-mantle geodynamics to melt processes and reservoirs.		Session Chair: Scientific Program Committee			
[Keynote] Oceanic propagators and the formation of oceanic crust in divergent margins	Webster Ueipass Mohriak	M216	2024-08-28 17:30	2024-08-28 17:45	1097
Significance of Chrome-spinel chemistry in mafic-ultramafic rocks of Pauni and Taka areas, Western Bastar craton, Central India: Implication for their tectonic setting	RAJKUMAR MESHRAM	M216	2024-08-28 17:45	2024-08-28 18:00	1098
A Study on the Volatiles of Monogenetic Volcanoes, Jeju Island, South Korea	MINJAE KANG	M216	2024-08-28 18:00	2024-08-28 18:15	1100
Trindade-Martin Vaz Archipelago petrological evolutionary insights recorded in fassaitic greencore clinopyroxene and REE evolutionary trends	Anderson SANTOS	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1102
The geochemical nature of serpentinites from the Mashhad mafic-ultramafic complex as an evidence for Palaeotethys oceanic crust subduction in NE Iran	KOUROSH MOHAMMADIHA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1103
S5 Ophiolite: A window to the oceanic mantle across the geological time		Session Chair: Scientific Program Committee			
Microdiamonds in Oceanic Mantle and Continental Volcanic Rocks Provide Significant Clues for the Earth's Two-Way, Deep Recycling System	Jingsui YANG	M216	2024-08-28 08:30	2024-08-28 08:45	1108
Ophiolites in the westernmost South Tien Shan: geochemical characterization and tectonic settings.	Bakhtier NURTAEV	M216	2024-08-28 09:00	2024-08-28 09:15	1104
Tectono-magmatic and metamorphic development of Shyok Ophiolite Belt from Ladakh Trans-Himalaya, India: Insights from microstructures, phase petrology, and P-T trajectory	Ravi Ranjan Kumar	M216	2024-08-28 09:15	2024-08-28 09:30	1110
Investigating Ca-Mg ionic exchange in Macquarie Island unobducted abyssal serpentinites	Cesare ALBASIO LODI-CUSANI	M216	2024-08-28 09:30	2024-08-28 09:45	1111
The origin of the DUPAL anomaly in the Tethys mantle domain	XIJUN LIU	M216	2024-08-28 09:45	2024-08-28 10:00	1106
Melts of sediment in the mantle wedge of the Neoproterozoic Fuchuan Ophiolite and the mark of subduction initiation	Wei WANG	M216	2024-08-28 10:00	2024-08-28 10:15	1116
New Data on Ophiolites of Western Chukotka, Northeastern Eurasia	Tatiana PILITSYNA	M216	2024-08-28 10:15	2024-08-28 10:30	1117
Identification of ca. 520 Ma MOR-type ophiolite suite in the inner Cathaysia Block, South China: Evidence from shearing-type oceanic plagiogranite	Longming LI	M216	2024-08-28 10:30	2024-08-28 10:45	1113
Neo-Tethyan ophiolites of Iran: formation of nascent oceanic lithosphere above double subduction	Iman MONSEF	M216	2024-08-28 10:45	2024-08-28 11:00	1115
PGE geochemistry of Macquarie Island basaltic glasses and picrites	Gyuchan PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1119
Early Neoproterozoic oceanic crust fragments in the Lhasa Terrane, Tibet	Peiyuan HU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1120
Tectonized Neotethyan lithosphere in southeastern Tibet: Results of the Luobusa ophiolite drilling	XiangzhenXU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1121

Title	Presenter	Venue	Start	End	Page
Ophiolites record plume-ridge interaction and two-stage oceanic crust accretion of the Meso-Tethys Ocean in the Central Tibetan Plateau	Yue RANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1123
Mantle heterogeneity caused by melt addition to mid-ocean ridge peridotite: Evidence from the Mid-Ocean Ridge Taitao ophiolite, southern	Weiwei WU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1125
Exhumation of mantle peridotite in an embryonic oceanic basin at slow to ultraslow spreading ridge within the Dahomeyide belt in Ghana, West Africa	Daniel KWAYISI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1126
Tectonomagmatic evolution of mantle complexes of the North Balkhash and Dzhalair-Naiman ophiolite zones (central and south Kazakhstan, western part of the Central Asian Orogenic Belt)	Aleksandra MILYUKOVA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1127
Olivine fabric and tectonic evolution of Indus-Yarlung suture zone: Insight from the Indus-Yarlung ophiolitic peridotite in the Tibetan Plateau	YU YANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1129
Geochemical study of ultrahigh pressure serpentinites from Chinese southwestern Tianshan and its implications	Tingting SHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1130
Petrogenesis of chromitites in the Bulqiza ophiolite massif, Albania and its records of Ti metasomatism	Tian QIU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1131
A case for subduction initiation in the Proto-South China Sea? Insights from the volcanic geology, petrology, and geochemistry of the Southern Palawan ophiolite	Nikko Manaig BALANIAL	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1132
Juxtaposed Cenozoic and Mesozoic ophiolites in Palawan island, Philippines: Implications for the evolution of western Philippines	Betchaida PAYOT	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1134
Petrography and geochemistry of intrusive rocks in northern Zambales and Pangasinan: Constraints on the evolution of northern Luzon	Mariz Lacson ALCANCIA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1135
Subduction initiation beneath an attenuated continental margin: Insights from the Timor ophiolite	Yu-Chin Lin	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1137
The Ginebra Ophiolithic Complex: Origin and evolution of an Ophiolite in Colombia from geochemistry and U-Pb geochronology.	Jonathan Adolfo HERNANDEZ PRIETO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1138
S6 The petrological and related tectonic interpretations of Northeast Asia		Session Chair: Scientific Program Committee			
[Keynote] East Asian Blocks: From Breakup of Rodinia to Assembly of Pangea	Guochun ZHAO	M216	2024-08-29 08:00	2024-08-29 08:30	1140
Petrogenesis of the circum-cratonic Triassic syenite province from the North China	Xu LIU	M216	2024-08-29 08:30	2024-08-29 08:45	1151
Oceanic isolation of the Paleo-Tethys from the Panthalassa in the leadup to the Permian mass extinction: Consistent evidence from metamorphism in East Eurasia	lei Zhao	M216	2024-08-29 08:45	2024-08-29 09:00	1165
Triassic tectonic response of overriding North China block to the South China block continental deep subduction	Lingtong MENG	M216	2024-08-29 09:00	2024-08-29 09:15	1160
Zircon U–Pb ages and Lu–Hf isotopes of the Paleozoic Maizuru Granites, Southwest Japan: Implications for the tectonic correlation between the Proto-Japan and Northeast Asia	Kenta KAWAGUCHI	M216	2024-08-29 09:15	2024-08-29 09:30	1148
The review on the Permo-Triassic continental collision process in the Northeast Asia during the final amalgamation stage of Pangea supercontinent and the geological correlations between Korea, China, and Japan.	Chang Whan OH	M216	2024-08-29 09:45	2024-08-29 10:15	1142
Origin and evolution of the Maizuru Belt, Southwest Japan: Implications for the crustal rearrangement tectonics along the Northeast Asian continental margin	Kenta KAWAGUCHI	M216	2024-08-29 10:15	2024-08-29 10:30	1152
Paleozoic tectonic evolution of the Guryong Group from detrital zircon records: Implications for the tectonic affinity of the eastern Gyeonggi Massif, Korean Peninsula	Ji Wan JEONG	M216	2024-08-29 10:30	2024-08-29 10:45	1154
Petrogenesis and structural analysis of pillow-like metabasalt rocks in Shangying in North China Craton defines Neoarchean fore-arc ophiolitic mé lange in accretional wedge	Zhiyuan CHEN	M216	2024-08-29 10:45	2024-08-29 11:00	1166
Tectonic and metallogenic evolution of the North China (Sino-Korean) Craton and the connection to the East Asian Continent	Mingguo ZHAI	M216	2024-08-29 14:30	2024-08-29 15:00	1144
Early to Late Mesozoic Tectonic Evolution and Associated REE Mineralization in Southern Mongolia: A Comparative Study of the Mushgai-Khudag and Lugiin Gol REE Deposits	Otgon-Erdene DAVAASUREN	M216	2024-08-29 15:00	2024-08-29 15:15	1146
Geology of Northeast Asian depicted by the Tanlu fault	Peng PENG	M216	2024-08-29 15:15	2024-08-29 15:30	1164
Discovery of the Oldest Rocks in Eurasia and its Implication for the Origin of the First Crust on the Earth	Xiao-Fei Qiu	M216	2024-08-29 15:30	2024-08-29 15:45	1163
The tectonic evolution from the Archean to Triassic in the north central Gyeonggi Massif (Hongcheon-Chuncheon area) in the Korean Peninsula, and its application to the tectonic evolution of the North China Craton	min su Kang	M216	2024-08-29 15:45	2024-08-29 16:00	1168
Late Tonian (ca. 780–750 Ma) bimodal magmatism in the Ogcheon Metamorphic Belt, Korea, at the eastern margin of North China Craton	Moonsup Cho	M216	2024-08-29 16:15	2024-08-29 16:30	1150

Title	Presenter	Venue	Start	End	Page
lithofacies paleogeography of the Upper Cambrian-Lower Ordovician in Jiyang Sub-basin of North China Plate: An evolution driven by Huaiyuan movement, climate and see-level	Hao GUO	M216	2024-08-29 16:30	2024-08-29 16:45	1161
Ages, Geochemical Characteristics and Tectonic Environment of Mesozoic Diorites in the Central Sulu Orogenic Belt	Shikuo LU	M216	2024-08-29 16:45	2024-08-29 17:00	1158
Cretaceous two stage extensional tectonics in Northeast Asia and its geodynamics	Wei LIN	M216	2024-08-29 17:00	2024-08-29 17:15	1159
Early Paleoproterozoic magmatism in the southern Trans-North China Orogen	Xiaoping LONG	M216	2024-08-29 17:30	2024-08-29 17:45	1156
Cenozoic intracontinental tectonics of Mongolia: A synthesized review	Ulambadrakh KHUKHUUDEI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1169
Petrogenesis of Paleoproterozoic granitic gneiss in the Geumsan area, Korea, and its tectonic implications for Northeast Asia	Shuhan PAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1172
Geochronological and geochemical evidence of the Ordovician magmatism in the Lake Zone, Western Mongolia	Batkhishig Bayaraa	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1174
Reporting the geochronology of the igneous rocks of the southern Jeonju area, located in the southwestern part of the Okcheon metamorphic belt, Korea	Hawon YUN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1176
Six subduction-accretionary mafic zones identified in the Altai orogenic belt, Xinjiang, China	Liu YONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1177
High-temperature and high-pressure metamorphism and anatectic events in the Khondalite Belt	Shuhan PAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1170
S7 General Topics		Session Chair: Scientific Program Committee			
Carbonatization and silicification of ophiolitic ultramafic rocks and formation of gold-bearing listvenites in the Arabian-Nubian Shield	Mokhles Kamal AZER	M216	2024-08-30 08:00	2024-08-30 08:15	1179
Carbonatite, ultramafic breccia, syenite, and alkaline basalts from the igneous and sedimentary association of the Bolivian rift	Ramiro Matos	M216	2024-08-30 08:15	2024-08-30 08:30	1183
Determination of low-content Ti in zircon by LA-ICP-MS/MS	junlong NIU	M216	2024-08-30 08:30	2024-08-30 08:45	1189
Controlling Factors of Granite Chemical Diversity and Implications for Early Crustal Evolution: Migmatites from the Southwestern Daqingshan Complex, North China Craton	Xingzhou JIANG	M216	2024-08-30 08:45	2024-08-30 09:00	1190
Updates on the IUGS Task Force on classification and nomenclature of igneous rocks	Michele LUSTRINO	M216	2024-08-30 09:00	2024-08-30 09:15	1200
A tale of two metamorphic belts in eastern Taiwan: petrological characteristics	Chin-Ho TSAI	M216	2024-08-30 09:15	2024-08-30 09:30	1195
Revisiting the crustal growth of the eastern Central Asian Orogenic Belt: Insights from the Erguna Massif and Duobaoshan area	Chenyang SUN	M216	2024-08-30 09:45	2024-08-30 10:00	1202
Pb isotope disequilibrium in metasediment-derived granitic melts	Lingsen ZENG	M216	2024-08-30 10:00	2024-08-30 10:15	1184
An improved Faraday cup configuration for Sr isotopic analysis using LA-MC-ICP-MS and its applying on rich-REE apatite	Xirun Tong	M216	2024-08-30 10:15	2024-08-30 10:30	1199
The significance of isotopic decoupling in the mafic-ultramafic layered sequence of the Bushveld Complex, South Africa	Peace ZOWA	M216	2024-08-30 10:30	2024-08-30 10:45	1187
Chronology and geochemistry of Triassic sanukitoids in Funing area, South China: Implications for petrogenesis and geodynamic processes	Zhenglin LI	M216	2024-08-30 10:45	2024-08-30 11:00	1185
Petrogenesis of the Early to Middle Miocene Mafic Volcanism of the Huantraico Sequence, Argentina	Carina GRECO	M216	2024-08-30 13:45	2024-08-30 14:00	1197
Early-mid Cenozoic extensional arc volcanism of the North Patagonian and the Southern Central Andes (33-43°S)	Lucia FERNANDEZ PAZ	M216	2024-08-30 14:00	2024-08-30 14:15	1191
Chromite formation during the ascent of orthopyroxene-bearing magmas produced by incongruent melting of garnet + clinopyroxene + olivine assemblages in the upper mantle: An experimental investigation	Tahnee OTTO	M216	2024-08-30 14:15	2024-08-30 14:30	1204
Petrology and Geochemical Studies of late Cenozoic basic-intermediate volcanic rocks Southwest of Ghezel- Ozan (NW Iran)	Hamoon MEMARIAN	M216	2024-08-30 14:30	2024-08-30 14:45	1178
Signature of Himalayan Orogenesis in Quaternary Sediments, Lalmonirhat District, Bangladesh: Evidence from Petrography and Mineral Chemistry	ISMAIL HOSSAIN	M216	2024-08-30 14:45	2024-08-30 15:00	1181
Petrological characteristics of the volcanic rocks of the Pugo Formation and Zigzag Formation: Insights on the arc evolution of the Central Cordillera, Philippines	ARA JOY APONGAN ABATAYO	M216	2024-08-30 15:00	2024-08-30 15:15	1193
Petrological and geochemical characteristicsof a suite of calc-alkaline granite from Mercara Shear Zone, West Dharwar Craton, India: Implications for tectono-magmatic process from a paleo continental arc setting & evidence of deep crustal melting.	Rigzin NORBOO	M216	2024-08-30 15:15	2024-08-30 15:30	1196
Geochemistry and petrogenesis of Janga Iron-Copper skarn deposit, Kerman province	Maliheh NAZARI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1206
Eoarchean crustal evolution of the North China Craton revealed by U-Pb ages, trace elements and Hf-O isotopes of detrital zircons from the Caozhuang quartzite	Hao Wang	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1207
Petrological and geochronological characteristics of the Bargilt Fe deposit in Mongolia	OYUNGEREL SODNOM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1209

Title	Presenter	Venue	Start	End	Page
Petrography and Geochemistry of Metamorphic Rocks in Logbadjeck Quarries (Littoral Region, Cameroon): Environmental Impact	Nkeng Enstein FORCHENALLAH	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1210
Syn-collisional crust-mantle interaction in Himalayan passive continental margin: a response to lithospheric flexure	Lin MA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1212
Late Ediacaran Magmatic Activity in the Southern Dom Feliciano Belt (Northeastern Uruguay): Insights from U-Pb Zircon Dating and Hf Isotopic Composition of Dikes	Elena Peel	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1214
A Preliminary Study of the Geostandards of the Granites and Obsidians using Neutron Activation Analysis and Electron Probe Micro Analysis	JIN MI-EUN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1216
Episodic continental evolution of the paleo-Pacfic margin along East Gondwana	Giun HAN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1217
Sr–Nd–Hf isotope and trace-element constraints on the origin of the HIMU reservoir of mafic-ultra mafic intrusions, Pechenga Greenstone Belt: A Potential mantle plume source in the asthenosphere	Sakine MORADI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1218
Protolith and metamorphic ages of eclogites from the Eastern Alps	Ruihong Chang	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1220
Proterozoic Zircons in Neogene Semporna Peninsula volcanic rocks and its indication of ancient continental crust in Northeastern Borneo	In-Hye MOON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1222
Age and Petrogenesis of appinite suites and high Ba-Sr granites in Chuncheon at the central Gyeonggi Massif, Korea	Tahnee OTTO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1223
T9 Structural Geology					
S1 3D geological mapping: international status, barriers, and perspectives of geomodelling		Session Chair: Philippe Calcagno			
[Keynote] Geomodelling by geological survey organisations: game changers, perspectives and challenges	Michiel Jan VAN DER MEULEN	C101	2024-08-27 08:00	2024-08-27 08:15	1235
Good Practices and Current Challenges of 3D Geological Modelling at the Czech Geological Survey	Ondřej ŠVAGERA	C101	2024-08-27 08:15	2024-08-27 08:30	1226
Construction of jurisdictional, federal, and multinational 3D geology to facilitate digital twins needed to address societal needs	Harvey Harvey Thorleifson	C101	2024-08-27 08:30	2024-08-27 08:45	1228
The Loop Project - an open-source platform for 3D geological modelling: towards better management of underground resources	Laurent AILLERES	C101	2024-08-27 08:45	2024-08-27 09:00	1229
LoopResources: Using structural frames for geostatistical simulations of geological resources.	Lachlan GROSE	C101	2024-08-27 09:00	2024-08-27 09:15	1231
Geomodelling in Europe: Sharing practices and open-sourcing tools among Geological Surveys	Laure PIZZELLA	C101	2024-08-27 09:15	2024-08-27 09:30	1232
3D Geological Modeling at BRGM (French Geological Survey)	Stephan Steuer	C101	2024-08-27 09:30	2024-08-27 09:45	1234
Heterogeneous internal architecture and engineering properties in an exhumed crustal scale strike-slip fault zone	Namgwon KIM	C101	2024-08-27 09:45	2024-08-27 10:00	1236
Germany 3D - Overview of 3D modelling activities of the German geological survey BGR	Stephan Steuer	C101	2024-08-27 10:00	2024-08-27 10:15	1238
Context is Everything: Leveraging a Common Reference Geological Model to Enhance Modeling Efficacy and Accuracy – A Case Study from Poland.	Zbigniew MALOLEPSZY	C101	2024-08-27 10:15	2024-08-27 10:30	1239
Role of basement tectonics and structural features in the seepage potential at the Cham –e Shir dam site, SW Iran	Arash Barjateh	C101	2024-08-27 10:30	2024-08-27 10:45	1224
Research on Key Technologies of 3D Geological Model Rendering in Cloud Environment	Yue SONG	C101	2024-08-27 10:45	2024-08-27 11:00	1225
Key Technologies for Geologic Modeling of Complex Fault Block Oil Reservoir	Xing DENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1241
S2 Shear Zone Tectonics		Session Chair: Durga Prasanna MOHANTY			
Syn-kinematic granite emplacement in a transpressional corridor and its influence on the formation of dome-and-basin fold interference patterns	Gideon Rosenbaum	C101	2024-08-26 16:00	2024-08-26 16:15	1242
Shear Zones of Southern Granulite Terrane, India: Networks and complications	Durga Prasanna MOHANTY	C101	2024-08-26 16:15	2024-08-26 16:30	1247
Structural analysis of Riedel synthetic shears influenced by the thickness of the brittle layers: the lesson from analog modeling with PIV technique	Marilia Barbosa VENÂNCIO	C101	2024-08-26 16:30	2024-08-26 16:45	1259
Kinematic vorticity and deformation thermometry analyses of the exhumed mylonites from the Xiaohe ductile shear zone in the sourthern Xiaoqinling gold province, North China	Hui-Min MA	C101	2024-08-26 16:45	2024-08-26 17:00	1248
Stages of Shear Zone Evolution in an Isotropic Medium: An Account of Fluid Induced Rheological Transformation in ~2.6 Ga Bundelkhand Granitoids of India	SAYAN MAITY	C101	2024-08-26 17:00	2024-08-26 17:15	1243
Structural investigation in the Madurai Block of Southern Granulite Terrane, India: Insights from Shear Zones	JOHN DSOUZA	C101	2024-08-26 17:15	2024-08-26 17:30	1245
Deep crustal expressions of exhumed continental-scale fault zone systems: Shear zone nucleation and initiation on rheological boundaries	Shuyun CAO	C101	2024-08-26 17:30	2024-08-26 17:45	1250
Polyphase deformation derived from meso- and microstructural observations along the brittle-viscous shear zone in the Hamyang, Korea	Sang Yeol Bae	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1251
Importance of Mechanical Anisotropy on Strain Partitioning across a Transpressional Shear Zone (Okdong Fault) in Korea	Jinhyeon SO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1252

Title	Presenter	Venue	Start	End	Page
Strain partitioning and Construction of Wuliangshan Coherent Fault System in Biluoxueshan-Chongshan shear zone, SW Yunnan in China	QIANQIAN Guo	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1253
The role of long-lived shear zones in reconstructing the tectonic and deformational history of ancient active margin systems – the case of the Clarke River Shear Zone (NE Australia)	Raiza Toledo Rodrigues	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1255
Delineation of a new Crustal-Scale Shear Zone in the Northern Bundelkhand Craton: The ~E-W trending Datia Shear Zone	AISHWARYA MOHAN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1256
Middle-lower crustal flow response to the India-Eurasia collision: structural evidence from the Chong Shan tectonic belt within the Sundaland block	Xiaoyu Chen	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1258
Southern West African Craton Strain Field derived from integrated structural mapping approach : tectonic and kinematic significance of shear zones	Kalidou TRAORE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1260
EXTERNAL VS. INTERNAL REFERENCES FOR KINEMATIC ANALYSIS OF A TRANSPRESSIVE SHEAR ZONE	SUSHMITA BHATTACHARJEE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1261
S3 Modern techniques for understanding faults and their effects on fault activity and fluid flow		Session Chair: Ho Gong-Ruei			
[Keynote] Illuminating fault zone structures in depth by dense seismic array	Haijiang Zhang	C101	2024-08-29 08:00	2024-08-29 08:20	1268
100Ma of slip events in the core of the Highland Boundary Fault, Scotland: implications for earthquake slip.	Zoe SHIPTON	C101	2024-08-29 08:20	2024-08-29 08:35	1269
Analysis of Subsurface Fault Systems Using Audio-Magnetotelluric Surveys in the Western Ilan Plain of Northeast Taiwan	Ping-Yu CHANG	C101	2024-08-29 08:35	2024-08-29 08:50	1263
How good is your fracture model? Examining how interpreter experience and approaches affect fracture model variability.	Leila Evans	C101	2024-08-29 08:50	2024-08-29 09:05	1265
Exploring the significance of favourable and unfavourable structures in Orogenic gold deposits through a numerical modelling approach	SWARNENDU BHUYAN	C101	2024-08-29 09:05	2024-08-29 09:20	1267
Fluid flow characteristics based on topological analysis of a fracture system in Sinseondae area, Geoje Island, Korea	Goeun KIM	C101	2024-08-29 09:20	2024-08-29 09:35	1262
Fractured feldspar clast as paleostress marker	Tridib Kumar MONDAL	C101	2024-08-29 09:35	2024-08-29 09:50	1264
Quantitative evaluation of fault connectivity and its petroleum significance based on topological analysis: a case study from the well H area, southern Sichuan Basin	jingru zhao	C101	2024-08-29 09:50	2024-08-29 10:05	1270
The Role of Thermal Buoyancy on the Permeable Faults: Insights from the Lattice Boltzmann Models	Soojung AN	C101	2024-08-29 10:05	2024-08-29 10:20	1271
The Orogenesis and Metamorphic Fabrics in the Western Pacific Subduction Zones since late-Miocene, the rock recored from strike-slip to collision	Gong-Ruei HO	C101	2024-08-29 10:20	2024-08-29 10:35	1272
ROOTLESS ORE DEPOSITS OF TIEN-SHAN	GENNADY ERMOLAEV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1273
Mapping gas hydrate and fluid flow indicators: potential linkage with the occurrence of slope instability processes in the northern Bay of Bengal, offshore Bangladesh	Vanessa MONTELEONE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1275
Microstructure of the fault rock drill cuttings from the enhanced geothermal system site in Pohang, South Korea: evidence of frictional melting	Sejin JUNG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1277
Investigation of seismic and aseismic slip behavior of large thrust and strike-slip faults through the integration of structural mapping, microstructural characterization, thermometric and stable isotopic analyses and numerical simulations (Ligurian Alps, Italy; Carg Project)	Silvio SENO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1278
Heterogeneity of burial-related fracture networks and its effect on strata permeability: Insights from a volcano-sedimentary sequence in Wido Island, Korea	Sodam PARK	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1280
The impact of dykes and large planar surfaces in the connectivity of fractured basalts of the Paraná-Etendeka Province, Southern Brazil	Francisco TOGNOLI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1281
S4 Fault damage zones in active and fossil faults		Session Chair: Fabrizio Agosta			
[Keynote] Fossil traces of co-seismic fluid flow in seismically active fault zones: studying the past to understand the present and possibly predict the future.	Luca SMERAGLIA	C101	2024-08-29 14:30	2024-08-29 14:45	1285
Architecture and properties of active faults, insights from active faults in southern Spain	Anita Torabi	C101	2024-08-29 14:45	2024-08-29 15:00	1284
Geometric characterization of Baza and Galera active faults, Baza Basin, southern Spain	Ofelia SILIO	C101	2024-08-29 15:00	2024-08-29 15:15	1287
Architecture of active and fossil fault zones in sedimentary rocks: Lessons from integrated structural, geomechanical and mineralogical analyses	Abhisek BASA	C101	2024-08-29 15:15	2024-08-29 15:30	1289
Multidimensional structural analysis of the reservoir-scale fault damage zones flanking the eastern side of the High-Agri-Valley Basin, southern Italy	Fabrizio AGOSTA	C101	2024-08-29 15:45	2024-08-29 16:00	1294
Characteristics of fault zone structure and the relationship with hydrocarbon migration and accumulation: a case study of Qiongdongnan Basin, South China Sea	Yannan DU	C101	2024-08-29 16:00	2024-08-29 16:15	1296
The western central African passive margin seismicity	Hardy NKODIA	C101	2024-08-29 16:15	2024-08-29 16:30	1293
The Dauki fault zone architecture and its implications for the evolution of the Shillong Plateau, Meghalaya	Vinee SRIVASTAVA	C101	2024-08-29 16:30	2024-08-29 16:45	1291

Title	Presenter	Venue	Start	End	Page
Damage Asymmetry and Earthquake Rupture Propagation	Young-Seog KIM	C101	2024-08-29 16:45	2024-08-29 17:00	1283
Brittle Deformation History based on Kinematic Analysis in Igidae, SE Korea	유비 오	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1297
Fault reactivation and vein localization along dikes in granitic rock, Gyeongju, Southeast Korea	Sehyeon GWON	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1298
Structural heterogeneities in exhumed fault core: result from Great Glen Fault, Scotland	Namgwon KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1299
Controls of deep strike-slip fault on fractures in the Tarim Basin, Northwest China: Insight from finite element numerical simulation	Yichen SONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1300
Quantitative characterization method of ultra-deep strike-slip fault damage zone based on facies-controlled seismic inversion	Lu LIU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1301
S5 Active faulting behavior, earthquake hazards zonation and urban prevention strategies: Field observation, data process and scene simulation		Session Chair: Scientific Program Committee			
Earthquakes and neotectonics in cratonic Australia	Haibin YANG	C101	2024-08-27 14:45	2024-08-27 15:00	1303
Multi-phase non-coaxial orogenic growth: propagation of the Longmen Shan thrust belt on the eastern margin of the Tibetan Plateau	Zhicheng ZHOU	C101	2024-08-27 15:00	2024-08-27 15:15	1306
Hunting for an invisible Holocene fault beneath an urban region using historic aerial photos	Junjie REN	C101	2024-08-27 15:15	2024-08-27 15:30	1309
Progress of active fault surveying and its frontier problems in China	Xiwei XU	C101	2024-08-27 15:30	2024-08-27 15:45	1310
Probabilities Seismic Hazard Modeling inferred from the newest fault slip rates and its effect on the Landslide Risks in the Eastern Tibet Region	Jia CHENG	C101	2024-08-27 15:45	2024-08-27 16:00	1313
Irregular Earthquake Recurrence of the Northern Kongur Shan Extensional System, NE Pamir: Constraints from Multiple Paleoseismic Methods	Jin GE	C101	2024-08-27 16:00	2024-08-27 16:15	1315
Paleoseismic investigating understanding “Whether the historical 1505 central Himalaya earthquake produced surface rupture??”	Shreya Arora	C101	2024-08-27 16:15	2024-08-27 16:30	1316
Structural characteristics of thrust system in the piedmont zone of middle part of Longmen Mountains during the Indosinian period	Na ZHENG	C101	2024-08-27 16:30	2024-08-27 16:45	1302
Active Son-Narmada-South Fault as major threat to dams in central India	VAIBHAVA SRIVASTAVA	C101	2024-08-27 16:45	2024-08-27 17:00	1305
Surface Ruptures of the February 6, 2023 Earthquake Sequence, eastern Tü rkiye	Tim Kusky	C101	2024-08-27 17:00	2024-08-27 17:15	1307
Anatomy of intracratonic Gondwana rift basins of Peninsular India: An integrated gravity, magnetic and remote sensing approach	SWARNAPRIYA CHOWDARI	C101	2024-08-27 17:15	2024-08-27 17:30	1312
Transient response of semi-elliptical hill with an elliptical tunnel under blasting and seismic loading	Hao Luo	C101	2024-08-27 17:30	2024-08-27 17:45	1317
Morphotectonic studies and identification of active faults in Qazvin city up to a radius of 50 km from its center.	Maliheh Norouzi	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1318
New insight into the mechanism and evolution of HorseTail splay folds: A case study from the Huayingshan fold belt(South China)	Zhang-peng LIU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1319
Bonded nanoparticles restrengthen faults during earthquake slip	Jianhua HUANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1320
Seismogenic structures of the 2022 M6.1 Lushan earthquake and M6.0 Maerkang earthquake sequence in western Sichuan, China	Chuanyou LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1321
3D modeling and seismic capablity assessment of the east margin fault of Daxing uplift in North China Plain	Zhengfang LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1323
Evidence of Quaternary surface rupturing in the southernmost end of the Yangsan fault and deterministic seismic hazard assessment in the Busan metropolitan area	Hyunjee LIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1325
Mechanism analysis of underground powerhouse structure-stress-controlled collapse in fractured rock mass: microseismic monitoring and numerical investigation	Yuepeng SUN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1327
The Characteristics of Geostress Field and Fault reactivation analysis Assessment in the Cucumber Mountain Area, southern Sichuan Basin	Zifan Zhu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1328
S7 Himalaya, Karakoram and Tibet: the geology and tectonics of a giant orogen		Session Chair: Scientific Program Committee			
[Keynote] Utilizing Multi-Mineral Multi-System Petrochronology to Unravel the Tectonic Development of the Himalaya	John COTTLE	C101	2024-08-28 14:30	2024-08-28 14:45	1334
Deformation-Time Constraints on the South Tibetan Detachment System in the Cuona area, eastern Himalaya	Hanwen DONG	C101	2024-08-28 15:00	2024-08-28 15:15	1331
Spatial and temporal stress variations along a continental megathrust: case study of the Himalayan Main Central Thrust	Djordje GRUJIC	C101	2024-08-28 14:45	2024-08-28 15:00	1344
Constraining the evolution of shear zones in the Himalayan mid crust in Central Nepal: implications for the exhumation of the Himalayan metamorphic core	Rodolfo CAROSI	C101	2024-08-28 15:15	2024-08-28 15:30	1332
The geodynamics of long-term convergence, Indian continental subduction and indentation at the India-Eurasia collision zone	Wouter Pieter SCHELLART	C101	2024-08-28 15:30	2024-08-28 15:45	1335
Break-up of Pangaea and Gondwana Reflected in the Tectonics of the Eastern Himalayan Syntaxis	Neptune Srimal	C101	2024-08-28 15:45	2024-08-28 16:00	1337

Title	Presenter	Venue	Start	End	Page
COMPLEX THICK- AND THIN-SKINNED THRUSTING WITHIN THE NW QAIDAM BASIN, TIBET, CHINA – OR HOW TO SALT THE DESERT	Piotr KRZYWIEC	C101	2024-08-28 16:00	2024-08-28 16:15	1342
Wedge-scale deformation in the Himalaya through time	Malay MUKUL	C101	2024-08-28 16:15	2024-08-28 16:30	1343
Unveiling the Hidden Dynamics: A Comprehensive Exploration of the Greater Himalayan Out-of-Sequence Thrust and Active Faults in the Sutlej River Section, India	RAJKUMAR GHOSH	C101	2024-08-28 16:45	2024-08-28 17:00	1329
Himalayan Influence Tectonic and Exhumation history of the Shillong Plateau and Mikir Hills, NE-India: Constraints from Low-temperature Thermochronological Analysis	RAMESH CHANDRA PATEL	C101	2024-08-28 17:15	2024-08-28 17:30	1339
Tectonic collision of Indian-Asian plates and the evolution of Himalaya foreland basin	KUN YU	C101	2024-08-28 17:30	2024-08-28 17:45	1341
Effects of structural position on the progressive evolution of internal shear zones from the Himalaya: Insights into orogenic wedge evolution	Kathakali BHATTACHARYYA	C101	2024-08-28 18:15	2024-08-28 18:30	1346
Magmatic and metamorphic evolution of the Late Cretaceous Muslim Bagh Ophiolite, western Pakistan: Implications for ridge subduction after subduction initiation	Takeshi IMAYAMA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1347
Neo-Tethyan subduction records in West Sulawesi, Indonesia	Xiaoran Zhang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1348
Cenozoic kinematic evolution of the Qilian Shan, northern Tibetan plateau: implication for the intraplate deformation	Bing LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1349
Kinematics and deformation conditions of the Chongshan strike-slip shear zone on the southeastern Tibetan plateau	Wenyuan LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1350
K-Ar dating of authigenic illite-bearing fault gouge constraints on Cenozoic multiple reactivation of the Lancangjiang Fault, SE Tibetan Plateau and its Tectonic Implications	Kui TONG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1351
Structural analysis, Geochronology and Thermochronology studies of the middle segment of the Xianshuihe-Anninghe-Xiaojiang Fault system: Implications for multiple-stage growth of the SE Tibetan Plateau margin	Zhiwu LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1353
Mechanism for the Uplift of Gongga Shan in the Southeastern Tibetan Plateau Constrained by 3D Magnetotelluric Data	Feng JIANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1355
Cenozoic tectonomagmatic history of South Tibetan Detachment System (STDS), Dhauliganga valley, NW Himalaya	GARGI GIRISH DESHMUKH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1356
Development Process of the West Kunlun Orogenic Belt Under the Control of Tethyan Evolution: Constraints from Detrital Zircon U-Pb Chronology of the West Kunlun Foreland Belt	Yang GAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1358
S8 From microscale to macroscale: multidimensional exploration in structural geology and tectonics	Session Chair: Rodolfo Carosi, Takeshi Imayama, Shuyun Cao, Oliver Lacombe				
[Keynote] Multiscale modern structural geology in metamorphic basements: exploring processes from the map to the atomic scale	Michele Zucali	C101	2024-08-28 08:00	2024-08-28 08:15	1368
EBSD-based microstructural characterization of the (ultra-) high pressure eclogite and retrogressed amphibolite from the Tso Morari Crystalline Complex in Ladakh, India	Dripta DUTTA	C101	2024-08-28 08:15	2024-08-28 08:30	1360
Nanogeoscience：A developing interdisciplinary	Yiwen JU	C101	2024-08-28 08:30	2024-08-28 08:45	1362
The effect of inherited basement strike-slip structures on rift basin architecture: insights from analog modeling and PIV analysis	Marilia Barbosa VENÂNCIO	C101	2024-08-28 08:45	2024-08-28 09:00	1363
Long-term stability of the Siberian craton: from “hot anchor” to “cold anchor”	Qin WANG	C101	2024-08-28 09:00	2024-08-28 09:15	1364
Microscopic Kinematic Indicators in the Achankovil Shear Zone, South India and its Tectonic Implications	Pratheesh PRABHAKARAN NAIR	C101	2024-08-28 09:15	2024-08-28 09:30	1367
Influence of salt diapir on the fault activity of subsalt units in salt-bearing fold-and-thrust belts: insight from natural example and numerical simulation	Wei WANG	C101	2024-08-28 09:30	2024-08-28 09:45	1370
Site investigation in a tunnel for unrevealing earthquake nucleation or "Finding the needle in the haystack"	Alba ZAPPONE	C101	2024-08-28 09:45	2024-08-28 10:00	1373
Microscale to mesoscale structures to constrain shear zone kinematics, a case study from the Shillong Plateau, NE India	SURAJIT MISRA	C101	2024-08-28 10:00	2024-08-28 10:15	1366
Graphitic material in fault zones: Implications for tectono-thermal evolution and carbon cycle	Shuyun CAO	C101	2024-08-28 10:15	2024-08-28 10:30	1372
Geometric and kinematic characteristics of along the strike-slip fault system: An example from the Yongdong fault system in central part of the Korean Peninsula	Kim JUN-YEOP	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1375
Progressive evolution of a type II shear zone: the Ferriere-Mollières Shear Zone (Argentera Massif, Western Alps, Italy)	Matteo Simonetti	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1377
Newly identified fold-and-thrust structures in the Ulsan Block of the Cretaceous Gyeongsang Basin, SE Korea, and their formation timing	Hyewon LIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1379
HT-LP extensional shear zones in the Metamorphic core of the Himalaya: preliminary ages, strain and P–T conditions	Salvatore IACCARINO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1381

Title	Presenter	Venue	Start	End	Page
Mapping polycyclic and monocyclic basement's units, and their relationships with oceanic-derived units, in the Western Alps: preliminary data from the Northern Dora Maira Massif	Salvatore IACCARINO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1382
Structure characteristics and its insights on shale gas exploration: an example from the Luzhou area, southern Sichuan Basin, China	zhengshuo MIAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1386
Crustal tectonic fabric in the Iberian Variscan slate belt: strong seismic anisotropy of slaty rocks partially preserved during homoaxial re-folding	Victor CARDENES	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1384
S9 Fault zones and fluid interactions, key structures for energy				Session Chair: Luca Smeraglia	
[Keynote] Reconstructing past fluid migrations in fold-and-thrust belts and forelands using geochemistry	Nicolas Beaudoin	C101	2024-08-30 09:30	2024-08-30 09:45	1401
Distributed faulting and fault growth by segment linkage in stratigraphic multilayers	Rob BUTLER	C101	2024-08-30 09:45	2024-08-30 10:00	1390
Preliminary data on fluid flow along the seismically active Yangsan fault	Luca SMERAGLIA	C101	2024-08-30 10:00	2024-08-30 10:15	1392
Synkinematic hydrothermal silicification in active normal faults: implications on the permeability structure of silicified faults	Luigi BERIO	C101	2024-08-30 10:15	2024-08-30 10:30	1396
Fluids and deformation processes at shallow subduction megathrust: hints from ancient analogues	Francesca REMITTI	C101	2024-08-30 10:30	2024-08-30 10:45	1398
Permeability structures of fault zones in low porosity carbonates	Fabrizio AGOSTA	C101	2024-08-30 10:45	2024-08-30 11:00	1388
Multistage structural controls on hydrothermal vein system development in epithermal mineral deposits: A case study of the Tieluping Ag–Pb–Zn deposit, East Qinling, China	Xinming ZHANG	C101	2024-08-30 13:45	2024-08-30 14:00	1394
Scale-dependent fracture patterns and flow in low-enthalpy geothermal targets: the role of diagenesis and contingent nodes	Stephen Laubach	C101	2024-08-30 14:00	2024-08-30 14:15	1402
Deciphering fluid sources and pathways of hydrothermal Ba-F mineralisation in western Bastar craton, central India: Using mineral system approach by combining structure, fluid, Sr- and S-isotope geochemistry	Muduru Lachhana Dora	C101	2024-08-30 14:15	2024-08-30 14:30	1399
Structural diagenesis of deep-buried carbonates controlled by strike-slip faults: an example from the Sinian Dengying Formation in Central Sichuan Basin	Shangzi LIANG	C101	2024-08-30 14:30	2024-08-30 14:45	1387
Infiltration of illuvial clays along the near-surface slip zone	Youngbeom CHEON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1403
The mechanism and its geological significance of Mesozoic red sandstone bleaching in Luxi block, North China Craton	Li LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1404
Identification of fault that triggered the 2017 Mw 5.4 Pohang Earthquake using the geothermal borehole (PX-2) cuttings	Hyunjee LIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1406
Pseudotachylytes in Gyeongju City, Jiri Mountain, and Maemul Island of Southeastern Korea: Its Occurrence and Characteristics	Hee-Cheol KANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1408
Determining the timing of fault activity using fluid behavior characteristics	TAE-HO LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1410
Pressurization and injection of fault materials and fluids during the long-term seismic cycle, the intraplate Yangsan fault, SE Korea	Chang-Min KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1411
Three-dimensional structural and parametric models focused on finding the leads for different applications connected with energy acquisition in NW part of Poland.	Rafał Laskowicz	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1412
S10 Geological architecture and active tectonics of Central and Eastern Himalayas				Session Chair: Scientific Program Committee	
Active fault mapping, structural framework, kinematics, and segmentation – An appraisal of the Chittagong Coastal Fault along the outer Indo-Burman Ranges	Md. Sakawat Hossain	C101	2024-08-30 08:00	2024-08-30 08:15	1416
Slab tear and its corresponding crustal deformation of subducted Indian lithosphere in the Eastern Himalayan Syntaxis region	Bo ZHANG	C101	2024-08-30 08:15	2024-08-30 08:30	1418
Landform Evolution of the Brahmaputra, Padma and Meghna interfluve, Bengal Basin, Bangladesh – A Pedological Approach	Md. Sharif Hossain KHAN	C101	2024-08-30 08:30	2024-08-30 08:45	1414
Investigating the relative roles of structural and mechanical (lithology, bed thickness) controls in fracturing in frontal thrust sheets: Insights from fracture characterization and attribute study, Eastern Himalaya, Sikkim	Kathakali BHATTACHARYYA	C101	2024-08-30 08:45	2024-08-30 09:00	1419
Petrotectonic framework of the Siwalik Group in northern part of the Chitwan Dun Valley, Central Nepal	Niraj Singh Thakuri	C101	2024-08-30 09:00	2024-08-30 09:15	1420
Miocene paleo-elevation constraints in the Tibetan Plateau: constraints of deuterium isotope from the Greater Himalayan Complex	Wentao GUO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1421
Mantle flow in the southeastern Tibet Plateau since the Eocene: From a geochemical perspective	Ziqing LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1422
S11+S6 General Topics				Session Chair: Scientific Program Committee	
Internal characteristics and main influencing factors of buried hill faults in the south Fault zone of Zhu III sub-basin, Pearl River Mouth Basin, China	zedong LIU	C109	2024-08-30 14:30	2024-08-30 14:45	1425
Analogue Modeling of Rift Evolution in the Central Africa Bongor Basin: A Dynamical Analysis from Dual Rifting to Reversal Processes	Yanjie GAO	C109	2024-08-30 14:45	2024-08-30 15:00	1426
The exhumation history of Qiangtang Basin since the Cretaceous and its control of hydrocarbon accumulation	Qingqing LEI	C109	2024-08-30 15:00	2024-08-30 15:15	1427

Title	Presenter	Venue	Start	End	Page
Zircon U-Pb geochronology of the weathering crust from Permian Maokou Formation, Western Hubei Province and its indication for Emeishan volcanic activity	Yaxian GAO	C109	2024-08-30 15:15	2024-08-30 15:30	1428
Development Characteristics and Formation Evolution of Cambrian Strike-Slip Faults in the Gaoshiti-Moxi Area, Sichuan Basin, SW China	Ruifeng Wang	C109	2024-08-30 15:30	2024-08-30 15:45	1429
Structural characteristics and development model of fluid diapirs within the structural transition zone, northern South China Sea	Yang QIN	C109	2024-08-30 15:45	2024-08-30 16:00	1431
The impact of fracture development patterns under tectonic influence on hydrocarbon productivity in the Bozi-Dabei region	冠南 仲	C109	2024-08-30 16:00	2024-08-30 16:15	1433
Characteristics of the Meso-Cenozoic fracture system in the Xihu Sag and its control of the basin	Jinhang Zheng	C109	2024-08-30 16:15	2024-08-30 16:30	1434
Characteristics of Unconformity and its Control on Buried Hill Hydrocarbon Reservoirs: A Case Study from the Qiongdongnan Basin, South China Sea	Yanying LI	C109	2024-08-30 16:30	2024-08-30 16:45	1436
The in situ stress field and microscale controlling factors in the Bozhong depression, Bohai Bay Basin	Guanjie ZHANG	C109	2024-08-30 16:45	2024-08-30 17:00	1437
Characterization of the Deformation and Formation Evolution of Mud Diapir Structure in the Rel Del Rey Basin, Niger Delta	Jixin ZHANG	C109	2024-08-30 17:00	2024-08-30 17:15	1439
The development characteristics and genetic mechanisms of inversion tectonics in the northern part of the Yinggehai Basin	qingbo WU	C109	2024-08-30 17:15	2024-08-30 17:30	1440
New lithostructural map of the Doropo region, northeast Côte d'Ivoire: insight from structural and aeromagnetic data	ZIANDJEDE HERVE SIAGNE	C109	2024-08-30 17:30	2024-08-30 17:45	1423
Quantitative prediction of tectonic fracture in Puguang gas field based on stress genesis	Hui LI	C109	2024-08-30 17:45	2024-08-30 18:00	1424
GEOLOGICAL ANALYSIS OF THE DEVONIAN COMPLEX IN THE SOUTHERN PART OF THE CASPIAN BASIN (KAZAKHSTAN)	Aliya ABLIGAZIYEVA	C109	2024-08-30 18:15	2024-08-30 18:30	1438
Boundary effects in the evolution of the deformation and stress field of southern Andean plateau, southern central Andes (26°30´–27°30´S)	Rodrigo QUIROGA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1445
Fractal Dimension Analysis in Breccias of the Colombian Emerald Belts	Camilo Andrés BETANCUR	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1447
The 'fault-controlled-fluid' diapir in Yinggehai Basin : a new understanding based on OBN data	Chenxi Chen Ma	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1448
New understanding of the evolution and structural deformation of the northern Neuquén Andes (37-38°S)	Lucía JAGOE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1450
Thermokinematic 2D restoration of the Marañón Fold and Thrust Belt in the Andes along the Puchca Valley, Perú.	CRISTIAN MIGUEL MACHACA SARDON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1452
New Understanding of Late Mesozoic Structural Deformation in the South Yellow Sea Basin and Its Significance for Oil and Gas Exploration	Huang ZHEN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1453
Effect of tectonic extrusion on the physical properties of clastic reservoirs*: *Based on physical simulation experiments	Yumeng Song	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1455
A Preliminary Study on the Sediment Source of the Maérzheng Formation in the Southern Margin of the East Kunlun Region, China	Lei PEI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1442
Tectonic significance of the Early Paleozoic ophiolite in the Central East Kunlun orogenic belt ， China	Lei Pei	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1443
Early Cretaceous lithospheric thinning of the North China craton: Insights from mantle-derived mafic dyke swarms in Jiaodong peninsula	Lei JI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1456
Analysis of effects of activities of Zahedan and Nosratabad faults on deformation and displacement dikes into zahedan poloton.(southeast of iran))	Zahra IRANI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1441
T10 Geomorphology					
S1+S6 Understanding Cover and its links with basement geology through Earth's history		Session Chair: Scientific Program Committee			
Neotectonics, geochemical dispersion processes and mineral exploration: linking basement and surface in regions of cover	Ignacio Gonzalez-Alvarez	M213	2024-08-30 13:50	2024-08-30 14:05	1457
Deciphering long-term geomorphological evolution through morphometric analysis of the Côa River drainage network (northeast Portugal)	Luca DIMUCCIO	M213	2024-08-30 14:05	2024-08-30 14:20	1458
The history of the most typical world's great rivers: the evolution of the Yangtze and Yellow rivers controlled by the Himalayan orogeny	Liankang YANG	M213	2024-08-30 14:20	2024-08-30 14:35	1460
Full-length Hiking Expedition along the Yellow River and Yangtze River, Discovery of Their earliest Sedimentary Layer, and Confirmation of a Complete Developmental Historical Profile	Liankang YANG	M213	2024-08-30 14:35	2024-08-30 14:50	1461
Danxia Landform research in China: Tectonic significance, fracture mechanisms and controlling factors	Fang REN	M213	2024-08-30 14:50	2024-08-30 15:05	1462
Controls of tectono-pluviometric forcing on landscape dynamics and seismicity in Java	Benjamin SAUTTER	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1463
Relationship between development periods of coastal sand dunes and climate-environmental factors	Min HAN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1464
Decadal and Millennium Scale Gully Expansion Rates, Mthatha, Eastern Cape, South Africa	Debbie Claassen	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1465

Title	Presenter	Venue	Start	End	Page
Karst morphologies in the foreland of the West-Congo belt, Republic of Congo: evidence of cone karst in the Madingou region	Nicy Tchiguina BAZEBIZONZA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1467
S2 'Landslides and climate changes' (IAG Co-Sponsored Session)		Session Chair: Scientific Program Committee			
Tackling Mediterranean Hurricanes through artificial intelligence in a near-future climate projection	Giovanni SCARDINO	M213	2024-08-30 08:00	2024-08-30 08:15	1468
Arctic landscape evolution in the warming climate of Svalbard: Permafrost degradation as a major driver of rock slide activity.	Dirk KUHN	M213	2024-08-30 08:15	2024-08-30 08:30	1471
Short-Term Climate Change (1981-2021) Impact on Landslide Events in South Sikkim, India	Ria NASKAR	M213	2024-08-30 08:30	2024-08-30 08:45	1473
Investigating the response of slow-moving landslides to climate and environmental changes in the Northern Apennines (Italy)	Vittoria VANDELLI	M213	2024-08-30 08:45	2024-08-30 09:00	1474
River bank falls of Anavilhanas extreme events in Negro river, Amazon state, Brazil	Cleide RODRIGUES	M213	2024-08-30 09:00	2024-08-30 09:15	1476
Detailed Survey and Quantitative Risk Assessment of Landslides in Mountainous Village: A Case Study in Jingyang Town, Hubei Province, China	Lei Liu	M213	2024-08-30 09:15	2024-08-30 09:30	1478
Impacts of rainfall-triggered landslides in New Zealand: déjà vu all over again	Martin Brook	M213	2024-08-30 09:30	2024-08-30 09:45	1479
Sea level rise and the 'hidden' landslides on the NW coast of Malta	Mauro SOLDATI	M213	2024-08-30 09:45	2024-08-30 10:00	1480
Climate change versus anthropic induced reactivation of slow-moving landslides in temperate environments	Mihai Niculiță	M213	2024-08-30 10:00	2024-08-30 10:15	1470
S4 Exploring high-resolution spatial and temporal data to resolve geologic and geomorphic processes		Session Chair: Scientific Program Committee			
Late Quaternary slip rate of the strike-slip faults on the eastern margin of the Qaidam Basin and its implication on the northeastern margin of the Tibetan Plateau	Guodong BAO	M213	2024-08-29 14:30	2024-08-29 14:45	1481
Optimization of InSAR based coseismic slip modeling for moderate earthquakes accounting for fore-aftershock sequence	Lejun LU	M213	2024-08-29 14:45	2024-08-29 15:00	1484
Field and UAV surveys of the northern Xainza rift, south-central Tibet: EW extension rates and earthquake hazard assessment	Marie-Luce CHEVALIER	M213	2024-08-29 15:00	2024-08-29 15:15	1485
Surface Rupture and Slip Distribution along the Chenghai fault mapped from airborne LiDAR data and its tectonic implications	Haomin Ji	M213	2024-08-29 15:15	2024-08-29 15:30	1486
Global basic landform mapping using 30-meter DEM for geologic and geomorphic research	Xingyu Zhou	M213	2024-08-29 15:30	2024-08-29 15:45	1488
Quantitative Assessment on Relative Tectonic Activity along Western Mae Chan Fault Zone, Northern Thailand	PICHAWUT MANOPKAWEE	M213	2024-08-29 15:45	2024-08-29 16:00	1490
Slip partitioning of the left-step Wulan segment along the right-lateral strike-slip Elashan fault	Jinrui LIU	M213	2024-08-29 16:00	2024-08-29 16:15	1492
Spatial Distribution and Regional Tectonic Significance of the Newly Discovered Kalawenguquan Fault in the Interior of the Tian Shan	Zhongtai HE	M213	2024-08-29 16:30	2024-08-29 16:45	1483
DATING ABANDONED ALLUVIAL SURFACES USING CALIBRATED MODELS OF GULLY INCISION	Amit MUSHKIN	M213	2024-08-29 16:45	2024-08-29 17:00	1493
Large-scale Traps Development and Hydrocarbon Accumulation along Transition Surfaces in Lacustrine Basin	Zhanlong Yang	M213	2024-08-29 17:00	2024-08-29 17:15	1494
New evidence of late Quaternary tectonic activity along the eastern margin of the Qaidam Basin	Zhikun REN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1495
Coseismic deformation of the 1976 Ms 7.3 Chaldiran earthquake in eastern Turkey measured by satellite imagery, in comparison with field measurements	Yu ZHOU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1497
Coseismic slip distribution of the 2023 earthquake doublet in Turkey and Syria from joint inversion of Sentinel-1 and Sentinel-2 data: An iterative modeling method for mapping large earthquake deformation	Jianlong Chen	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1498
Long-term influence of seismic activity on hot spring observation	Tian LEI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1499
Application of geological and geomorphological data in ground motion simulation	Jiangyi LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1500
A study on high-resolution 3D seismic velocity structure in southern Sichuan basin, China, using a local temporary network	Yang ZANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1501
Relationship between seabed geomorphology and flexural subsidence in the Sibari and Corigliano basin (Southern Italy)	Nora Markezic	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1502
Application of Acoustic Classification for Seabed Characteristics of Spratly Islands in the South China Sea	Yin Hsuan Liao	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1503
S5+S3 The role of climate, tectonics and surface processes in landscape evolution of the Himalayan-Tibetan orogen		Session Chair: Scientific Program Committee			
Investigation of the genesis and development of the late Pleistocene paleosols for the reconstruction of the geomorphic evolution of the loess deposits near Gorgan, Iran	Sahar MALEKI	M213	2024-08-29 08:00	2024-08-29 08:15	1505
Multi-phase drainage rearrangement in response to geodynamic mechanism transition in southeastern Tibet	YONG ZHENG	M213	2024-08-29 08:15	2024-08-29 08:30	1514

Title	Presenter	Venue	Start	End	Page
Tectonic Segmentation along the Himalayan Arc from Geomorphic Analysis and its implication on the Strength of the underthrusting Indian Lithosphere	Raj Sunil KANDREGULA	M213	2024-08-29 08:30	2024-08-29 08:45	1510
Geomorphological evidence of neotectonic activity in the Ganga-Brahmaputra plains: A review	CHINMAY DASH	M213	2024-08-29 08:45	2024-08-29 09:00	1515
Understanding the Long-Term Impacts of Human Activities and Climate Change on the Krishna-Godavari Delta through Remote Sensing	RESHMA KADAKATH NARANTHATTA	M213	2024-08-29 09:00	2024-08-29 09:15	1508
Mangroves ecosystem metamorphosis impacted by climate change in Indus Delta	Ping YIN	M213	2024-08-29 09:30	2024-08-29 09:45	1517
Sediment characteristics and carbon stock in mangroves of Mahanadi delta in western Bay of Bengal	KAKOLI BANERJEE	M213	2024-08-29 09:45	2024-08-29 10:00	1520
Identification and classification of the Salehyeh wetland sediments and assessment of possible contamination markers (toxic elements)	Nayerehsadat BAYAT GHIASI	M213	2024-08-29 10:00	2024-08-29 10:15	1507
The climate-tectonic interplay in Ladakh, NW Himalaya (India)-Records during the Quaternary Period	Binita PHARTIYAL	M213	2024-08-29 10:15	2024-08-29 10:30	1511
Quaternary Tectonism and Channel Migration in the Banas River, Western India M.R. Resmi and Manisha Gupta	Resmi M.R	M213	2024-08-29 10:30	2024-08-29 10:45	1519
Tectonic landforms and Morphometric analysis of the frontal part of the Belt of Schuppen: Focus on Naga Thrust	SENTISENLA JAMIR	M213	2024-08-29 10:45	2024-08-29 11:00	1513
Sustainable Habitability of the Mountain Valley Systems under Emergent climatic transition: A case of the Himalaya	Satish Jagdeo SANGODE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1522
The Ganga Plain rupture cyclicity deduced from the terminal fans; and its coherency with the Himalayan earthquake cycles	PITAMBAR PATI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1523
The enigmatic Sarasvati River: Unravelling the mystery through space and time-A multidisciplinary approach	HARSH TEWARI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1524
Comparative analysis of sea level changes along the South Sea coast in South Korea during the Holocene Thermal Maximum	JUNGHYUNG RYU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1526
T11 Paleontology and Paleoanthropology					
S1 Cambrian Explosion and Co-evolution of environment		Session Chair: Scientific Program Committee			
[Keynote] Isoxys volucris from the lower Cambrian Sirius Passet lagerstätte: a spiny solution to avoid predators	Arne Thorshøj NIELSEN	C201-202	2024-08-27 08:00	2024-08-27 08:15	1560
Kuanchuanpu biota – An early Cambrian Orsten-type Lagerstätte yielding the earliest ecdysozoan body fossils	Huaqiao ZHANG	C201-202	2024-08-27 08:15	2024-08-27 08:30	1527
Adaptive specialization of hexactinellid sponges from the early Cambrian black shales of southern China	Hao YUN	C201-202	2024-08-27 08:30	2024-08-27 08:45	1528
Cambrian small skeletal fossil bioprovinces and their application to test paleogeographic models	Michael STEINER	C201-202	2024-08-27 08:45	2024-08-27 09:00	1531
Chronology of the Ediacaran-Cambrian Boundary：Discussion with new data from Aksu area of Xinjiang Province, China	Ben YANG	C201-202	2024-08-27 09:00	2024-08-27 09:15	1533
TriBE: An international working group dedicated to understanding the early Palaeozoic dispersal and radiation of trilobites, and first results on trilobite palaeobiogeographical patterns	Harriet Bethany B. DRAGE	C201-202	2024-08-27 09:15	2024-08-27 09:30	1538
Crown group sponges from the Nama Group of Namibia, and the evolution of spiculogenesis across the Ediacaran-Cambrian transition	Alex George LIU	C201-202	2024-08-27 09:45	2024-08-27 10:00	1540
Ediacaran chronostratigraphy: falling into place or falling into pieces?	Dmitrii GRAZHDANKIN	C201-202	2024-08-27 10:00	2024-08-27 10:15	1542
Preservation of arthropods and microbes in Cambrian Orsten Lagerstätten	Nikita SOZONOV	C201-202	2024-08-27 10:15	2024-08-27 10:30	1544
Putative soft-bodied structures in early Cambrian Orsten-type fossil lagerstätten of the Yangtze Platform	Yuqian CHEN	C201-202	2024-08-27 10:30	2024-08-27 10:45	1552
The structural diversity of mollusk shells in early Cambrian	Luoyang LI	C201-202	2024-08-27 10:45	2024-08-27 11:00	1554
Systematics of the Redlichiidae (Redlichiida, Trilobita) and related groups	Zhixin SUN	C201-202	2024-08-27 14:30	2024-08-27 14:45	1541
The anterior sclerite in early arthropods	Mengxiao YU	C201-202	2024-08-27 14:45	2024-08-27 15:00	1537
Ventral Morphology and Their Ecological Implications of Two Xandarellids from Chengjiang Biota, China	Maoyin ZHANG	C201-202	2024-08-27 15:00	2024-08-27 15:15	1535
3D morphologies of the early Cambrian Chengjiang arthropods	Yu LIU	C201-202	2024-08-27 15:15	2024-08-27 15:30	1534
Spatially and temporally dynamic marine redox state through late Ediacaran-early Cambrian: evidence from carbonate I/Ca proxy	Ruliang HE	C201-202	2024-08-27 15:30	2024-08-27 15:45	1536
Morphological comparison with Cambrian relatives reveals the evolution of tardigrades	Ji-Hoon Kihm	C201-202	2024-08-27 15:45	2024-08-27 16:00	1557
Evolution in Polar Ecosystems: The Early Ordovician of Morocco and France	Gaëtan JM POTIN	C201-202	2024-08-27 16:15	2024-08-27 16:30	1556
Cambrian Burgess Shale-type fossil Lagerstätten of North China	Pingli WANG	C201-202	2024-08-27 16:30	2024-08-27 16:45	1555
Complete radiodonts from the early Cambrian Chengjiang fauna: implications on radiodont evolution	Han ZENG	C201-202	2024-08-27 16:45	2024-08-27 17:00	1549
A tiny Cambrian euarthropod illuminates the early evolution of mandibulates	Yao Liu	C201-202	2024-08-27 17:00	2024-08-27 17:15	1548
Taxonomic revision of Dickinsonia Sprigg	Nikita SOZONOV	C201-202	2024-08-27 17:15	2024-08-27 17:30	1546
Continental weathering during the Great late Ediacaran Glaciation revealed by Mg isotope	TIANZHENG HUANG	C201-202	2024-08-27 17:30	2024-08-27 17:45	1567

Title	Presenter	Venue	Start	End	Page
Phosphatised calcified cyanobacteria at the terminal Ediacaran and the earliest Cambrian transition stage: Response to the paleoenvironment	Xiao MIN	C201-202	2024-08-27 17:45	2024-08-27 18:00	1530
Preliminary study on Cambrian shell fossils from the Xiweikou Section in Yuncheng, Shanxi , China	Zhao Wang	C201-202	2024-08-28 08:00	2024-08-28 08:15	1558
Comparison of mineralized skeleton and microstructure of early Cambrian tubular animals	Jingliang ZHAO	C201-202	2024-08-28 08:15	2024-08-28 08:30	1562
Shallow water fauna from deep-water deposits, in the Zhaolaoyu Formation, late Ordovician at Fuping area, southern Ordos Basin	Caibin ZHANG	C201-202	2024-08-28 08:30	2024-08-28 08:45	1564
Evolutionary significance and biological affinities of Ediacaran to Cambrian tubular fossils	Yuze WANG	C201-202	2024-08-28 08:45	2024-08-28 09:00	1565
Did ctenophores construct colonies in the Ediacaran?	Vladislav DESIATKIN	C201-202	2024-08-28 09:30	2024-08-28 09:45	1550
Characterisation of Carbon isotope of the Cambrain Jialao Formation, Jianhe County, Guizhou Province, China	Zhen LI	C201-202	2024-08-28 09:45	2024-08-28 10:00	1559
Morphogenesis simulations unravelling novel recognition biases in Paleozoic trilobite injuries	Xiaoyong YAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1568
Isolated radiodont mouths: case study of two unique oral cones from the Fezouata Shale Formation (Early Ordovician, Morocco).	Gaëtan JM POTIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1569
Modularity and fluctuating asymmetry in the early Cambrian trilobite Protoryctocephalus arcticus from the 'Tsinghsutung' Formation, South of China	Esteve JORGE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1571
Taxonomy and Morphology of Choia from the Qingjiang Biota	Laiyuan Wu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1573
New artiopodan euarthropods from the Chengjiang fauna (Cambrian, Stage 3) at Malong, Yunnan, China	Yuyan ZHU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1574
Ecological and environmental implications of predatory groups in the Cambrian Guanshan Biota	Deguang JIAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1575
S2 The Evolution of Land Plants and Plant–Environment Interactions during Geological Time		Session Chair: Jinzhuang Xue			
[Keynote] In situ preservation enhances systematic study: a case in research of the Wuda Tuff Flora, Inner Mongolia	Jun WANG	M218	2024-08-29 08:00	2024-08-29 08:15	1582
Mineralogical characteristics of pedogenic carbonates in Devonian paleosols and their environmental implications	jingru LUO	M218	2024-08-29 08:15	2024-08-29 08:30	1576
Biomarkers in fossil resins (ambers) – diversification and application	Paweł Kosakowski	M218	2024-08-29 08:30	2024-08-29 08:45	1589
Devonian coevolution of forests and tetrapods	Gregory RETALLACK	M218	2024-08-29 08:45	2024-08-29 09:00	1577
A preliminary study of three vascular plants from the Middle Devonian Haikou Formation of Qujing, Yunnan Province, China	Gaofeng ZHENG	M218	2024-08-29 09:00	2024-08-29 09:15	1578
Coupling relationship between radiation of early vascular plants and the long-term water cycle	Jinzhuang XUE	M218	2024-08-29 09:15	2024-08-29 09:30	1579
The cycle of S element in pyrite from Carboniferous bauxite in South china	Yulei CHEN	M218	2024-08-29 09:30	2024-08-29 09:45	1581
The Middle-Late Triassic Boundary Extinction: Palynological evidence	Yuewu SUN	M218	2024-08-29 09:45	2024-08-29 10:00	1584
New material of Radula heinrichsii (Radulaceae, Porellales) from mid-Cretaceous Myanmar amber	Xiangbo SONG	M218	2024-08-29 10:00	2024-08-29 10:15	1585
Tracking Darwin's climbing plants in a 298 Ma swampy forest	ZHOU WEIMING	M218	2024-08-29 10:15	2024-08-29 10:30	1586
Eusporangiate Fern from the Early Permian Peat-forming Forest in Wuda, Inner Mongolia, China	Dandan LI	M218	2024-08-29 10:30	2024-08-29 10:45	1587
Palaeodepositional environment, implications of Glossopteris flora, and organic matter characteristics from Early Permian Period, Karo OCM, East Bokaro Coalfield, Damodar Basin, India	Suraj Kumar SAHU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1591
Organo-floral characteristics of the Jagannath coal mine (Talcher Coalfield) from Mahanadi Basin: Implications to Paleoecology, Paleovegetation and depositional settings	DEVESHWAR PRAKASH MISHRA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1593
Vegetation and climate oscilations during MCO/MCT in Central and Eastern Paratethys	Marianna Kováčová	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1594
Palynofloral Succession on the Cretaceous-Paleogene Transition in Northeast China	Yuewu SUN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1595
Middle-Late Permian Palynofloras in lacustrine-pluvial fan depositional system in Junggar Basin, northern Xinjiang, China	Yuewu SUN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1597
The Leaf Fossils of Tuff Units in Metro Manila and Rizal, Philippines	Andrea Pamintuan	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1599
S3 Ostracoda in Geology, the 5th Asian Ostracod Meeting (AOM)		Session Chair: Yaqiong Wang			
[Keynote] Time Machine Biology: ostracod examples	Moriaki YASUHARA	C201-202	2024-08-26 16:10	2024-08-26 16:30	1605
Late Ordovician ostracods of Valcour Island, New York State, USA	Yichi ZHANG	C201-202	2024-08-26 16:30	2024-08-26 16:45	1606
Late Devonian benthic ostracods from South China and their response to the Frasnian–Famennian event	Junjun SONG	C201-202	2024-08-26 16:45	2024-08-26 17:00	1604
Exceptional preservation of reproductive organs and giant sperm in the Cretaceous ostracods	He WANG	C201-202	2024-08-26 17:00	2024-08-26 17:15	1601

Title	Presenter	Venue	Start	End	Page
Cretaceou stratigraphy and ostracod funa in the Songliao Basin, NE China	Dangpeng XI	C201-202	2024-08-26 17:15	2024-08-26 17:30	1613
Ostracod Faunas from the Early Cretaceous Liupanshan Group (Pingliang, NW China): Implications for Biostratigraphy and Palaeoenvironment	Yaqiong WANG	C201-202	2024-08-26 17:30	2024-08-26 17:45	1600
[Keynote] Phenotype Puzzle: Challenges in Paleontological Studies	Yanhong PAN	C201-202	2024-08-26 18:00	2024-08-26 18:20	1602
A review of non-marine ostracod faunas from the Cretaceous Gyeongsang Basin, South Korea	Byung-Do CHOI	C201-202	2024-08-26 18:35	2024-08-26 18:50	1603
Distribution and community structure of ostracods across the Isthmus of Panama	Kk Aye	C201-202	2024-08-26 18:50	2024-08-26 19:05	1607
Ecological Impact of the Suez Canal: Distribution and Diversity of Invasive Ostracods in the Mediterranean Sea	Lalita WEERACHAI	C201-202	2024-08-26 19:05	2024-08-26 19:20	1608
Testing the deep-sea glacial disturbance hypothesis as a cause of low, present-day Norwegian Sea diversity	Anna JÖST-KIM	C201-202	2024-08-26 19:20	2024-08-26 19:35	1611
OSTRACOD ASSEMBLAGES OF THE MIDDLE MIOCENE TRANSGRESSIVE SEDIMENTS IN THE CARPATHIAN FOREDEEP (JAWORZNO, SW POLAND; THE CENTRAL PARATETHYS)	Zbigniew Jan ZIAREK	C201-202	2024-08-26 19:35	2024-08-26 19:50	1609
No-marine Ostracod fauna from the Early Cretaceous Jinchuan Formation of the Ordos Basin: Taxonomy and Biostratigraphy	Yaqiong WANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1614
Geochronology and biostratigraphy study on the Early Cretaceous basins in the Jilin region, northeastern China	Yu-Ting ZHONG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1615
Holocene hydroclimate changes in the source area of the Yellow River inferred from ostracod assemblages and their isotopes in Lake Gyaring	Xiangzhong LI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1617
PALEOZOOGEOGRAPY OF THE LOWER CREATACEOUS QUIRICÓ FORMATION, SÃO FRANCISCO BASIN, MINAS GERAIS STATE, BRAZIL: A STUDY BASED ON LIMNIC OSTRACODS	Amanda MOREIRA LEITE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1618
Holocene ostracod assemblages and paleo-water depth from a raised beach sediment near Lake Suribachi-Ike, East Antarctica	Satoshi SASAKI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1620
Reconstructing Global Diversification Pattern of Non-marine Cypridoidea from Fossil Occurrence Data	Wonseop LIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1621
A new record of Notodromadidae (Ostracoda) from southern Thailand: preliminary result	Anisong Chitnarin	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1622
Spatiotemporal changes of Ostracoda and paleoenvironment in brackish Lake Nakaumi (SW Japan) in relation to climatic and anthropogenic influences since the Little Ice Age	Toshiaki IRIZUKI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1623
PALEOZOIC OSTRACODS FROM MONGOLIA	Yarinpil ARIUNCHIMEG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1625
PLIOCENE NON-MARINE OSTRACODS FROM THE SHARGA BASIN	Belgutei BOLD	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1627
NON MARINE OSTRACODA FROM THE CRETACEOUS OF THE TSOGT-OVOO BASIN IN MONGOLIA	Jalbaa UNDARIYA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1628
The study of AI deep learning Yolov5 algorithm analysis for distinguish Ostracoda in meiofauna microscope pictures	Hyunsu YOO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1630
S4 Paleocene-Eocene larger benthic Foraminifera, paleobiogeography and collision of Indian and Asian Plates		Session Chair: Yaqiong Wang			
Paleocene-Eocene Larger Benthic Foraminifera from Meghalaya and Indo – Myanmar Orogenic belt of Eastern Tethys, India, collision of Indian –Asian plates and global paleobiogeography	VINOD TEWARI	M218	2024-08-29 14:30	2024-08-29 14:45	1631
[Keynote] Larger Benthic Foraminifera: Valuable Proxies in Biostratigraphic Evaluation of Paleogene Carbonate and Siliciclastic Sequences in Indian Petroliferous Basins	VINOD TEWARI	M218	2024-08-29 14:45	2024-08-29 15:00	1637
Foraminiferal assemblage and palaeoenvironmental reconstruction of early Eocene Umlatodoh Limestone form south Shillong Shelf: Signature of ETM2?	T. Ngamlengin Haokip	M218	2024-08-29 15:00	2024-08-29 15:15	1633
LARGER BENTHIC FORAMINIFERA (LBF) BIOSTRATIGRAPHY OF PALEOCENE – EOCENE SEDIMENTS IN PARTS OF ASSAM SHELF OF ASSAM AND ASSAM ARAKAN BASIN WITH REFERENCE TO DEPOSITIONAL ENVIRONMENT	KALPANA KALITA	M218	2024-08-29 15:15	2024-08-29 15:30	1635
Biostratigraphy Bentic Foraminifers of Triassic- Jurassic boundary in Zagros Basin (SW Iran)	Vahid AHMADI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1639
S5 Functional morphology and biomechanics in invertebrates: new ecological and evolutionary perspectives		Session Chair: James Nebelsick			
[Keynote]Distinct causes underlie double-peaked trilobite cephalon disparity, but this disparity is unrelated to exoskeleton moulting behaviour	Harriet Bethany DRAGE	C201-202	2024-08-28 15:45	2024-08-28 16:00	1642
[Invited] Exploring patterns of adaptive evolution across the Cambrian trilobite radiation	James Dougal HOLMES	C201-202	2024-08-28 14:00	2024-08-28 14:15	1646
Insights into raphiophorid trilobite glabella spine as a sensory organ for collective behaviour	Esteve JORGE	C201-202	2024-08-28 15:00	2024-08-28 15:15	1640
Enrolment in trilobites: insights for development and phylogeny	Esteve JORGE	C201-202	2024-08-28 15:30	2024-08-28 15:45	1641
Computational fluid dynamics simulation indicates morphological selection of the Upper Ordovician graptolite dicranograptids by hydrodynamics	Wenhui Wang	C201-202	2024-08-28 15:15	2024-08-28 15:30	1644
Biomechanics of the echinoid skeleton and its relevance to ecological reconstructions and preservation potentials in the fossil record	James NEBELSICK	C201-202	2024-08-28 14:30	2024-08-28 14:45	1645

Title	Presenter	Venue	Start	End	Page
[Keynote] Integrative Ordovician stratigraphy of China: a critical constraint on orogenies and palaeogeographical evolution of NE peri-Gondwana	Yuandong ZHANG	C201-202	2024-08-28 14:15	2024-08-28 14:30	1661
S6 Early Palaeozoic faunas and palaeobiogeography of NE peri-Gondwana		Session Chair: Scientific Program Committee			
The Ordovician radiolarians from Qilian Orogenic Belt	Hui LUO	C201-202	2024-08-28 14:45	2024-08-28 15:00	1666
Uppermost Darriwilian radiolarians from the lower part of Wulalike Formation, NW Ordos Basin, North China	Xuejin WU	C201-202	2024-08-29 10:00	2024-08-29 10:15	1665
New techniques for studying the morphology of chitinozoan plugs	Yan LIANG	C201-202	2024-08-29 10:15	2024-08-29 10:30	1663
The global distribution of Upper Ordovician acritarchs	Kui YAN	C201-202	2024-08-29 10:30	2024-08-29 10:45	1653
The Ordovician-Silurian boundary deposits in northwestern Tarim, Xinjiang: the Xikeer bed (new unit) and its implications	Yuchen ZHANG	C201-202	2024-08-29 10:45	2024-08-29 11:00	1657
[Keynote] Methods for β-level paleobiogeography using dendrogram and cladogram	Dong-Chan LEE	C201-202	2024-08-29 14:30	2024-08-29 14:45	1648
New insights into the Great Ordovician Biodiversification Event: Evidence from the Early Ordovician Liexi Fauna	Xiang Fang	C201-202	2024-08-29 14:45	2024-08-29 15:00	1650
Latest Ordovician graptolite fauna of the Wufeng Formation in South China	Qing CHEN	C201-202	2024-08-29 15:00	2024-08-29 15:15	1660
Silurian conodonts from western Yunnan and Xizang (Tibet), China	Zhongyang CHEN	C201-202	2024-08-29 15:15	2024-08-29 15:30	1664
Early Darriwilian evolution of North China conodont bioprovince: insights from sedimentology and conodont biostratigraphy	Sehyun Cho	C201-202	2024-08-29 15:30	2024-08-29 15:45	1668
The Middle Ordovician Bivalves from Dali, Yunnan Province, SW China and their palaeogeographic significance	Yong WANG	C201-202	2024-08-29 15:45	2024-08-29 16:00	1647
Middle–Late Ordovician cephalopod fauna from southern Xizang (Tibet) and its palaeogeographic implications	Jiaqi SONG	C201-202	2024-08-29 16:00	2024-08-29 16:15	1649
Early Paleozoic reef evolution in the Taebaek and Yeongwol groups, Korea: Insights into the peri-Gondwanan reef development	Jeong-Hyun LEE	C201-202	2024-08-29 16:30	2024-08-29 16:45	1671
A distinctive type in the earliest Phanerozoic reef pattern: calcimicrobial-cement reefs from the Cambrian Series 2 Xiannüdong Formation, China	Daecheol KIM	C201-202	2024-08-29 16:45	2024-08-29 17:00	1651
Oldest stromatoporoid reefs are found in South China	Juwan JEON	C201-202	2024-08-29 17:00	2024-08-29 17:15	1655
Mollusk-dominated skeletal contributions during the Great Ordovician Biodiversification Event (GOBE) in the Darriwilian Sino-Korean Block	Myung-Jun Seo	C201-202	2024-08-29 17:15	2024-08-29 17:30	1670
Paleozoic oxygenation event - evidence from late Silurian tubular trace fossils in South China	Yuxuan WANG	C201-202	2024-08-29 17:30	2024-08-29 17:45	1659
The last episode of coral-stromatoporoid biostromes and faunal changes across a Devonian-Carboniferous Boundary section of South China	Kun LIANG	C201-202	2024-08-29 17:45	2024-08-29 18:00	1667
Recovery of the earliest Silurian paleo-ocean: coupling evidence from both benthos and redox conditions in South China	Wenhui Wang	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1672
First report of Late Ordovician sponge spicules assemblage from the Yangtze Platform, South China	Lixia LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1673
Carbon isotope stratigraphy of the Lower Ordovician Dumugol Formation: Implications for global correlation	Eunsoo LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1675
Biogeographic shifts of marine invertebrates during the Ordovician-Silurian transition	shasha LIU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1676
Graptolite biostratigraphy of the Ordovician Wulalik Formation in western margin of North China	Huaqing WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1677
S7 Recent advances in palaeontology from Asia (APA open session)		Session Chair: Yongdong Wang, Byung-do CHOI			
[Keynote] New record of the conifer wood taxon Brachyoxylon from the Middle Jurassic in southwestern China, and a global survey of paleobiogeography of the Mesozoic Brachyoxylon occurrences	Yongdong WANG	C201-202	2024-08-30 08:00	2024-08-30 08:15	1692
The first record of the genus Prosantorhinus (Perissodactyla: Rhinocerotidae) of East Asia	Danhui SUN	C201-202	2024-08-30 08:15	2024-08-30 08:30	1683
Deciphering the Evolutionary Dynamic of Melanosomes in Mammalian hair	Xin LI	C201-202	2024-08-30 08:30	2024-08-30 08:45	1681
Evolution and dispersal of vertebrates in the Tibetan Plateau and surrounding regions	Tao DENG	C201-202	2024-08-30 08:45	2024-08-30 09:00	1679
Fossil evidence reveals sexual dimorphism in Anchiornis huxleyi	Yibo Zhou	C201-202	2024-08-30 09:00	2024-08-30 09:15	1678
Four endemic taxa of chondrichthyans from the Late Ladinian (Middle Triassic) of Guizhou and Yunnan Provinces, South China	Siyan ZHAO	C201-202	2024-08-30 09:15	2024-08-30 09:30	1693
Stromatoporoids from Upper Ordovician rocks of southern Kazakhstan and their palaeobiogeographical implications	Juwan JEON	C201-202	2024-08-30 09:30	2024-08-30 09:45	1688
The oldest pig-nose turtle (Carettochelyidae) in the Early Cretaceous of South Korea	Minguk KIM	C201-202	2024-08-30 09:45	2024-08-30 10:00	1707
The oldest Gondwanan record of durophagous shark Strophodus Agassiz, 1838 (Hybodontiformes) from the Kachchh Basin, western India	Suraj Bhosale	C201-202	2024-08-30 10:00	2024-08-30 10:15	1702
Fossil insects from China: a review	Diying HUANG	C201-202	2024-08-30 10:15	2024-08-30 10:30	1698
The review of Protopsyllidioidea in China	Xinneng LIAN	C201-202	2024-08-30 10:30	2024-08-30 10:45	1697
Revision of Mesopsyche and description of new species of Turbidapsyche gen. nov., from the late Middle Triassic Tongchuan entomofauna: taxonomic and paleogeographic implications	Xinneng LIAN	C201-202	2024-08-30 10:45	2024-08-30 11:00	1695
New Umenocoleidae (Dictyoptera) from the Jinju Formation, South Korea	SooBin LEE	C201-202	2024-08-30 14:00	2024-08-30 14:15	1694

Title	Presenter	Venue	Start	End	Page
Molecular taphonomy of Oligocene marine mammal bones from Hokkaido, Japan	Raman UMAMAHESWARAN	C201-202	2024-08-30 14:15	2024-08-30 14:30	1684
Multidirectional "shuttle dispersal" model and human origins	Xijun NI	C201-202	2024-08-30 14:30	2024-08-30 14:45	1686
Shells for understanding Hong Kong subtidal ecosystem history: a conservation baseline	Pedro Juliao JIMENEZ	C201-202	2024-08-30 14:45	2024-08-30 15:00	1690
The lower Barremian Bkassine (Lebanon) dysodile Konzentrat and Konservat-Lagerstätte: Insights on the fossil continental assemblages and reconstruction of the depositional environment	Diying HUANG	C201-202	2024-08-30 15:00	2024-08-30 15:15	1700
Memorial of Prof. Martin G. Lockley: The Dinosaur and Pterosaur Tracks of the Korean Peninsula	Min HUH	C201-202	2024-08-30 15:15	2024-08-30 15:30	1703
The earliest calcareous peyssonneliacean red algae fossils from Ordovician: systematics, evolutionary and paleoecological significance	weiling ZHUANG	C201-202	2024-08-30 15:30	2024-08-30 15:45	1705
DISCOVERY AND GEOLOGICAL SIGNIFICANCE OF PHOSPHATIZED ANIMAL RESTING EGG FOSSILS IN THE CHANG 73 MEMBER, YANCHANG FORMATION, ORDOS BASIN	Dexiang GAN	C201-202	2024-08-30 15:45	2024-08-30 16:00	1708
New discoveries of the fossil lampreys from the Yanliao and Jehol Biotas, North China	Feixiang Wu	C201-202	2024-08-30 16:00	2024-08-30 16:15	1710
Early Cambrian evaporite deposits in the North China Craton and their event stratigraphic, paleogeographic, and paleoenvironmental implications	Bin WAN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1711
Taxonomy and taphonomy of fossil fish scales from the Lower to Middle Miocene of eastern part of Shimane Prefecture, Japan	Mami HAMADA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1712
Phylogeny of the Trigonioididae	Seong Young YANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1713
New insights into pterosaur cranial anatomy: X-ray imaging reveals palatal structure and evolutionary trends	He CHEN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1714
S8+S9 The floral diversity variation and palaeoenvironmental background across the terrestrial Triassic and Jurassic transition		Session Chair: Scientific Program Committee			
Tracing Palaeo-Gaseous Mercury Variations through Fossil Plants: Preliminary Analysis of Mercury Concentration Data in Extant *Ginkgo* and Extinct Ginkgoaleans	Li Zhang	C201-202	2024-08-29 08:00	2024-08-29 08:15	1715
Mesozoic Climate change and CO2 concentration variation - paleobotanical evidence from China	Yongdong WANG	C201-202	2024-08-29 08:15	2024-08-29 08:30	1716
The linkage between Carnian Pluvial Episode and volcanism recorded by mercury anomalies in South China	Qing LI	C201-202	2024-08-29 08:30	2024-08-29 08:45	1717
The Mesozoic vegetation of Madagascar and the Jurassic vegetation of the Mahajanga Basin, northwestern Madagascar	Vivi Vajda	C201-202	2024-08-29 08:45	2024-08-29 09:00	1718
Atypical element accumulation in fossil leaves from the end-Triassic of Northern Hemisphere	Susan NEHZATI	C201-202	2024-08-29 09:00	2024-08-29 09:15	1720
First fossil foliage record in the red beds from the Upper Jurassic in the Sichuan Basin, southern China	Yongdong WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1721
Early Jurassic plants response to the Toarcian Ocean anoxic event in the Ordos Basin, China	Yunfeng LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1722
Preliminary report on pterosaur track from the Cretaceous Jindong Formation, Gyeongsang Supergroup, Goseong County, South Korea	Hyeokpyo JEON	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1723
S10 General contributions to Paleontology and Paleoanthropology		Session Chair: Rowan Martindale			
NaOH solution: a novel approach to extract microfossil trapped in cherts	Manuel RIGO	C201-202	2024-08-28 16:00	2024-08-28 16:15	1725
A new research on ultra-large ichthyosaur-Himalayasaurus tibetensis	Qinghua SHANG	C201-202	2024-08-28 16:15	2024-08-28 16:30	1730
New Pachymeridiidae (Insecta: Heteroptera: Pentatomomorpha) fossils from the Jinju Formation (Lower Cretaceous), South Korea	Jun-Hyeok JANG	C201-202	2024-08-28 16:30	2024-08-28 16:45	1732
CENOZOIC BIOSTRATIGRAPHY APPROACH FROM EQUATORIAL CARBONATE PLATFORM OF BRAZIL	Orangel AGUILERA SOCORRO	C201-202	2024-08-28 16:45	2024-08-28 17:00	1733
Paleobiodiversity of the Tamengo and Guaicurus formations (Ediacaran-Cambrian boundary strata, Brazil): paleoecological, paleogeographic and biostratigraphic implications	Rodrigo ADORNO	C201-202	2024-08-28 17:00	2024-08-28 17:15	1735
New Record of Elasmobranch (shark) fauna from the early Miocene (Aquitanian) of Kachchh Region (western India): Palaeoenvironmental and Palaeobiogeographic significance	Ketan CHASKAR	C201-202	2024-08-28 17:15	2024-08-28 17:30	1737
Neocomian ammonites from Talesh region (NW Alborz Mountains, Iran)	MAHMOUDREZA Majidfard	C201-202	2024-08-28 17:30	2024-08-28 17:45	1724
Study of Quaternary Radiolaria from the Core ABP-06, Station II, Section 1, Central Indian Ocean	DEEKSHA BOHRA	C201-202	2024-08-28 17:45	2024-08-28 18:00	1726
Ecological impacts of the Early Jurassic climate crises	Sinjini SINHA	C201-202	2024-08-28 18:00	2024-08-28 18:15	1727
Cranial elements of Temnospondyl from the Middle Triassic of Satpura Basin, Madhya Pradesh, India.	Savita Nilkanth CHAURPAGAR	C201-202	2024-08-28 18:15	2024-08-28 18:30	1729
Traces of Predatory Drilling Behavior on Middle to Late Pliocene Mollusc Fossils from Santo Domingo, Ilocos Sur, Northern Philippines	David Cabahug POLICARPIO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1738
Response of foraminifers to the Hangenberg mass extinction during the Devonian-Carboniferous transition in South China	Yang SHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1739

Title	Presenter	Venue	Start	End	Page
Bone Histology of the Sabertooth *Smilodon populator* and *Puma concolor* from Brazil	Virginia Silva Maciel	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1740
Pleistocene-Holocene Molluscan Fossil Assemblage and Paleoenvironment Analysis of the Damortis Uplifted Marine Terrace Sequence in Santo Tomas, La Union, Philippines	John Paul Martinez Mondala	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1741
Thermal maturity and taxonomic insights from palynomorph coloration: Preliminary results for the immature sediments of the Cretaceous, Yezo Group	Maho HAYAKAWA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1742
OPal: Open Palaeontology – a community-driven diamond open access journal with preregistration	Harriet Bethany DRAGE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1744
METHODOLOGICAL DEVELOPMENT FOR EXTRACTING THREE-DIMENSIONAL SPECIMENS OF CLOUDINA LUCIANOI (BEURLEN E SOMMER, 1957)	Rodrigo Rodrigues ADORNO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1745
***Glossifungites* : Tracing the Subterranean Artistry of Ancient Ecosystems from the Baisakhi Formation of Jaisalmer Basin, Rajasthan, India**	ANSHUL HARSH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1749
Miocene vertebrates of Kutch, Gujarat, India: An implication on Indian-Asian post collision faunal diversification and paleobiogeography	Kongrailatpam Milankumar SHARMA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1750
Discovery of the *Fictovichnus* from the Fatehgarh Formation of Barmer Basin from India	PAWAN KUMAR	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1752
Microconchid-cement reefs from the Visean of Belgium	Jeong-Hyun LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1753
Growth behaviour and palaeoecological role of microproblematica Palaeoaplysina in the Late Carboniferous to the Early Permian of Svalbard	Juwan JEON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1747
T12 Resource Geology and Economic Geology					
S1 Resource Prospecting of Critical Metals and Economic Processing		Session Chair: Scientific Program Committee			
PERSEPHONE – Autonomous Exploration and Extraction of Deep Mineral Deposits	Marko KOMAC	C203-204	2024-08-26 16:00	2024-08-26 16:15	1754
Gallium distribution and enrichment in skarn iron deposits: Insights from the Zhuchong deposit, Eastern China	Wang FANGYUE	C203-204	2024-08-26 16:15	2024-08-26 16:30	1756
Geochemical characterization of Rare Earth Elements and Rare Metal Potentials, Neoproterozoic, Peralkaline rhyolite of Malani Igneous Suite, Jodhpur, District, Rajasthan	Mukesh Kumar MISHRA	C203-204	2024-08-26 16:30	2024-08-26 16:45	1760
The Main Type, Characteristics And Genesis of Brine Li Deposits in China's Continent	Chenglin LIU	C203-204	2024-08-26 16:45	2024-08-26 17:00	1763
Carbonatites and their potentiality for Niobium mineralisation in Central block of eastern Ambadungar: Indicated Resource for critical mineral	BIJAY KUMAR DAS	C203-204	2024-08-26 17:00	2024-08-26 17:15	1757
Unlocking the Exploration Potential of Critical Minerals in South Korea	Andrew Kim	C203-204	2024-08-26 17:15	2024-08-26 17:30	1761
Geochemical Variations of Critical Elements in Angouran Zn-Pb Deposit, Iran: Insights from New La-ICP-MS Analysis	Mohammad AMINI	C203-204	2024-08-26 17:30	2024-08-26 17:45	1765
FUTURAM: Developing methodologies for mining waste characterisation	Anna LADENBERGER	C203-204	2024-08-26 17:45	2024-08-26 18:00	1758
The Critical Metal Potential of Pb-Zn Deposits in the Canning Basin: A case study of Goongewa, Lennard Shelf	Jenna McGovern	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1766
ECONOMIC COOPERATION BETWEEN SOUTH KOREA AND UZBEKISTAN ON CRITICAL METALS.	NAVRUZBEK JAHONGIR UGLI JURABEKOV	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1767
Phoscorite as a possible source for phosphate and REE: A first report from Chaitma Alkaline Province, Korba district, Chhattisgarh.	NIBIN G TOM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1768
The study of Critical Raw Materials in the Czech Geological Survey	Anna VYMAZALOVA MAITI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1770
A review of China's resources of lithium in coal seams	chao LIU	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1771
S2 Exploration Targeting of Critical Metals		Session Chair: Scientific Program Committee			
New developments for minerals discovery in the 21st century	Sandra Occhipinti	C203-204	2024-08-27 14:30	2024-08-27 14:45	1772
The evolving potential of the Australian REE ecosystem	Ignacio Gonzalez-Alvarez	C203-204	2024-08-27 14:45	2024-08-27 15:00	1774
Detailed exploration targeting of LCT pegmatite deposits in the central-part of Rajasthan, India	Alok PORWAL	C203-204	2024-08-27 15:00	2024-08-27 15:15	1777
Uranium Exploration targeting in the Mineral System Approach	Patrick LEDRU	C203-204	2024-08-27 15:15	2024-08-27 15:30	1780
Geochemical vectors to LCT pegmatites: the compositional data analysis approach.	Bijal Chudasama	C203-204	2024-08-27 15:30	2024-08-27 15:45	1783
Discovery of Ion-Adsorption Rare Earth Element Deposits by Geochemical Exploration in Southwestern China	ZHOU JIAN	C203-204	2024-08-27 15:45	2024-08-27 16:00	1776
Cassiterite trace element discrimination plots for critical mineral exploration	Avish Avnith KUMAR	C203-204	2024-08-27 16:15	2024-08-27 16:30	1786
A Preliminary Overview of the Metallogenetic Provinces of Southern Angola	Enrique Merino Martinez	C203-204	2024-08-27 16:30	2024-08-27 16:45	1778

Title	Presenter	Venue	Start	End	Page
Indonesian Critical Mineral and Energy Transition	Muhammad Wafid AGUNG NOVIANTO	C203-204	2024-08-27 16:45	2024-08-27 17:00	1782
Critical-metal related alteration mineral mapping using hyperspectral data: A new approach using ensemble of Support Vector Machines and Extreme Value Theory	Sandeepan DHOUNDIYAL	C203-204	2024-08-27 17:00	2024-08-27 17:15	1784
Regional-scale exploration targeting of Rare Earth Elements associated with carbonatite-alkaline complexes: a comprehensive prospectivity study in northwestern India	Malcolm Aranha	C203-204	2024-08-27 17:15	2024-08-27 17:30	1787
Exploration targeting of northern Finland for CRMs hosted in ultramafic-mafic orthomagmatic intrusions	Malcolm Aranha	C203-204	2024-08-27 17:30	2024-08-27 17:45	1789
Criteria for forecasting and assessment of tin-tantalum-lithium mineralization in Eastern Kazakhstan	NataLya ZIMANOVSKAYA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1791
Machine learning approach to predict distribution of critical elements : REE + Y contents in the Iranian karst-type bauxite deposits	Giovanni MONGELLI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1793
LocatOre: Mineral Exploration and Vectoring Software	Stephen Alexander COOKE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1795
The characteristics and use of calcrete as a sample medium for gold exploration in the Karibib area	NAILOKE SHALI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1796
GEOLOGICAL INVESTIGATION OF THE CHIMBIYA NIOBIUM-TANTALUM (Nb-Ta) ANOMALY IN KASUNGU DISTRICT, CENTRAL MALAWI.	Chrispin Ngwata	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1797
Mafic ultramafic rocks around Bachihalli-Hulihalli area, Holenarsipur Schist Belt, Western Dharwar Craton, South India: indications for Zn rich environment	KALYAN PAL	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1799
Analysis of Lithium-Bearing Pegmatite Mineral System in the Alvand Plutonic-Metamorphic Complex, Western Iran	Majid Keykhay-Hosseinpoor	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1800
Possibility of lignite coal deposits of South Korea as an unconventional REE deposit; preliminary case study of Gyeongju-Yeongil coal field	Woohyun CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1801
Mineral resources exploration in SW Angola (PLANAGEO Project)	Iván MARTÍN-MÉNDEZ	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1803
Structural control on gold mineralisation in the Ngubevu area (South Africa) inferred from micro-scale to regional-scale spatial analysis	Nolukholo Sinovuyo Busakwe	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1805
Geology and Copper-Sulphide mineralisation within the Mutale area, Soutpansberg Group, South Africa	Thangeni Mphanama	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1806
Identifying target areas for copper mineralization using ASTER and geochemical data in Musina Area, Limpopo Mobile Belt, South Africa	Humbulani Rejune MUNDALAMO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1807
Reconnaissance Phase of Chromite Potential in Iran	SHAFIGHEH TARKIKORDEDEHI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1808
Quantitative Data for Geochemical Exploration of critical elements: The Contribution of Handheld LIBS	Naila MEZOUED	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1810
S3 Granitic Pegmatite-Hosted Critical Mineral Deposits		Session Chair: Scientific Program Committee			
[Keynote] Lithium pegmatites of Africa - a review	Kathryn Goodenough	C203-204	2024-08-27 09:30	2024-08-27 09:45	1819
Ore deposits of critical minerals in Indian granitic pegmatites	Yamuna SINGH	C203-204	2024-08-27 09:45	2024-08-27 10:00	1811
The legacy of Petr Černý in the study of granitic pegmatites	Tania MARTINS	C203-204	2024-08-27 10:00	2024-08-27 10:15	1816
Multidisciplinary Approach to Exploring for Rare-Element Pegmatites in Western Australia	Paul DUURING	C203-204	2024-08-27 10:15	2024-08-27 10:30	1817
New age data for the rare metal pegmatites of the East Sayan rare metal belt	Anna IVANOVA	C203-204	2024-08-27 10:30	2024-08-27 10:45	1812
Deep Learning Application in Predictive Mineral Targeting of Southwestern Uganda: Leveraging Airborne Magnetic and Radiometric Data	Christopher ALEXIS	C203-204	2024-08-27 10:45	2024-08-27 11:00	1814
Rare metal potential of North-Western Kalba (Eastern Kazakhstan)	Tatyana Oitseva	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1820
Pressure relevance of pegmatite melt evolution: new insight about melt-melt-fluid immiscibility imprinted in pegmatite quartz	Woohyun CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1822
Mineralogical and geochemical properties of the pegmatite zircons: Implications for the formation of immiscible melt and fluid during pegmatite evolution	Youseong Lee	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1823
Metallogenesis of superlarge W-Cu ore systems in South China: Exampled by Zhuxi and Dahutang ore deposits	Xiaofei PAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1824
The use of lithium as a Critical Mineral in Granitic Pegmatite	Alla DIAW	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1826
Genesis of the Koktokay pegmatitic rare-metal deposit (Altai, China): Constraints from the newly-recognized Triassic rare-metal leucogranite	Ping SHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1827
S4 Co-Ni mineralization mechanism related to sedimentary, metamorphic, magmatic and weathering processes		Session Chair: Scientific Program Committee			
[Keynote] Origin of Cu-Co mineralization in the Central African Copperbelt: Neoproterozoic syn-sedimentary-diagenetic processes overprinted by Pan-African orogenic mineralization events	Huimin SU	C203-204	2024-08-27 08:00	2024-08-27 08:15	1829

Title	Presenter	Venue	Start	End	Page
Major types of Co-Ni deposits and their exploration in China	Shao-Yong JIANG	C203-204	2024-08-27 08:15	2024-08-27 08:30	1832
Unlocking critical metal resources from the Avebury metasomatic Ni sulfide deposit, Western Tasmania, Australia	JOSE LUIS BARILLAS DIAZ	C203-204	2024-08-27 08:30	2024-08-27 08:45	1833
Resource Potential Evaluation of Magmatic Cobalt and Nickel in the East Kunlun Metallogenic Belt, Northwest of China	Feng ZHANG	C203-204	2024-08-27 08:45	2024-08-27 09:00	1835
Occurrence patterns and controlling factors of Co in the world-class Panzhihua Fe-Ti oxide deposit, SW China: implications for Co mineralization	Banxiao RUAN	C203-204	2024-08-27 09:00	2024-08-27 09:15	1836
Geochemical anomalies related to cobalt-nickel mineralization in the Eastern Kunlun Orogen, China	Yue LIU	C203-204	2024-08-27 09:15	2024-08-27 09:30	1831
Mineralization of Ni-Co and other critical metals in Early Cambrian black shales in the Yangtze Block of South China	Jing-Hong YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1838
Platinum Group Elements and associated magmatic sulfide mineralization in the Tantalite Valley Complex, Southern Namibia	Daniel Reuben Ferreira	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1840
Linking Selective Alteration, Mineral Compositional Zonation and Sulfide Melt Emplacement in Magmatic Ni-Cu Sulfide Deposits	Mengmeng Cui	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1842
Ni-PGE enrichment in the Jaguar and Jatobá IOCG deposits, Carajás district, Brazil	Yuri Tatiana CAMPO RODRIGUEZ	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1843
Geology and cobalt occurrence of the Cihai iron-cobalt deposit, eastern Tianshan, Xinjiang, China	Wei MEI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1845
The origin and mineralization processes of the Dulenggou copper-cobalt deposit in Eastern Kunlun metallogenic belt, western China	Wei WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1846
Mineralogy and geochemistry of nickel laterite deposit in the Acoje block of the Zambales ophiolite, Philippines	Akane ITO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	1847
S5 Mining for a Better Energy Future: Sustaining the Supply of Critical Raw Materials		Session Chair: Tunde Muritala ARISEKOLA			
CRM-geothermal: Raw materials from geothermal fluids	David Govoni	C102	2024-08-30 08:00	2024-08-30 08:15	1852
Resource potential of Russian Federation for critical raw materials. Lithium factor	Oleg KAZANOV	C102	2024-08-30 08:15	2024-08-30 08:30	1851
Certification of Competencies in Geosciences in Africa: Facts, Fictions, Geopolitical Considerations and African Union Perspectives	Tunde ARISEKOLA	C102	2024-08-30 08:30	2024-08-30 08:45	1854
AfricaMaVal – Building Africa-EU partnerships on sustainable raw materials value chains: focusing on business network with upstream and downstream companies	Marko KOMAC	C102	2024-08-30 08:45	2024-08-30 09:00	1849
Major global producers of critical minerals in extraction and processing stages	JI WON MOON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1856
Rare Earth Elements and Yttrium (REY) enrichment in mining wastes from Tinto river area (SW Spain)	Francisco Javier González	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1857
Serpentinization in the Malawi Rift- a potential to power the energy transition.	Chikumbutso Cyril KAMBILONJE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	1859
S7 Petroleum Enrichment and the Tethys Geodynamic System		Session Chair: Scientific Program Committee			
[Keynote] Hydrocarbon enrichment in basins influenced by Tethyan evolution: A comparative analysis of the Persian Gulf Basin and the Sichuan Basin	Zhiliang HE	C203-204	2024-08-28 09:30	2024-08-28 09:45	1863
Differential hydrocarbon accumulation and enrichment in the northern Kuqa foreland basin, western China	Xinzhuo Wei	C203-204	2024-08-28 09:45	2024-08-28 10:00	1861
The Impact of Tethys Evolution on Petroleum Accumulation in Kuqa, Papua, and Zagros Foreland Basins	shunqi CHAI	C203-204	2024-08-28 10:00	2024-08-28 10:15	1870
The trace metal content in oils: a global approach	Svetoslav GEORGIEV	C203-204	2024-08-28 10:15	2024-08-28 10:30	1875
Geochemical characteristics, genetic types and sources of gas accumulations in the northern Jizhong Subbasin, Bohai Bay Basin, eastern China	NIAN LIU	C203-204	2024-08-28 10:30	2024-08-28 10:45	1908
Main Features and Controlling Factors of Hydrocarbon Basins in the eastern Tethys Tectonic Domain	Xiaowei FU	C203-204	2024-08-28 10:45	2024-08-28 11:00	1869
Characteristics and Resource Potential of East Indonesia Basin Group in Eastern Tethys: A Comprehensive Assessment	Shijie ZHAO	C203-204	2024-08-28 14:30	2024-08-28 14:45	1867
Two-stage oil accumulation in the Ediacaran Dengying Formation at central Sichuan Basin: Insights from dolomite U-Pb and pyrobitumen Re-Os dating	Bin DENG	C203-204	2024-08-28 14:45	2024-08-28 15:00	1866
Organic petrological and geochemical characteristics of lower Paleozoic marine shale	Sherry (Xiaowei) Zheng	C203-204	2024-08-28 15:00	2024-08-28 15:15	1883
Structure and Stratigraphic Architecture of Lake Edward Basin, Uganda: Implications for Petroleum System Analysis	Lauben TWINOMUJUNI	C203-204	2024-08-28 15:15	2024-08-28 15:30	1882
A machine learning method reveal the variations of organic matter enrichment mechanisms of freshwater vs. saline lacustrine oil shales driven by paleoclimate	Man LU	C203-204	2024-08-28 15:30	2024-08-28 15:45	1874
Structural characteristics and evolution processes of intracratonic strike-slip faults: A case from the Gaoshiti-Moxi area, central Sichuan Basin, SW China	Qingqi ZHAO	C203-204	2024-08-28 15:45	2024-08-28 16:00	1881
Post-rifting uplift and inversion of intra-plate basin: implication from the Doseo basin, Central Africa	Yifan SONG	C203-204	2024-08-28 16:15	2024-08-28 16:30	1865

Title	Presenter	Venue	Start	End	Page
Charging and leakage of natural gas in the YL13-1 structure, Qiongdongnan Basin	Yongbin QUAN	C203-204	2024-08-28 16:30	2024-08-28 16:45	1872
Genetic mechanism and pore evolution of deeply-buried high-quality conglomerate reservoirs of the Paleocene Kongdian formation, Bozhong Depression, Bohai Bay basin	Xiaojun PANG	C203-204	2024-08-28 16:45	2024-08-28 17:00	1877
Integration of Rock physics and Geological processes in reservoir Properties Characterization. A case study applied on Plutonio Field of the West African Congo Basin	Mukhtar HABIB	C203-204	2024-08-28 17:00	2024-08-28 17:15	1879
GASEOUS ANOMOLIES FOUND IN AGRICULTURE FIELD AROUND SAGAR Distt., SOUTHERN FRINGES OF BUNDELKHAND REGION, MADHYA PRADESH. INDIA	AKANKSHA SAHU	C203-204	2024-08-28 17:15	2024-08-28 17:30	1885
Characteristics of effective fracture development in deep-ultra-deep reservoirs and its impact on gas reservoir productivity	Xixue ZHANG	C203-204	2024-08-28 17:30	2024-08-28 17:45	1886
Petroleum system development in the Iranian Zagros Basin in response to the Neo-Tethys evolution	Tianhou LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1888
Hydrocarbon charging process and phase evolution in the lower to middle Jurassic in Qiudong Sag, Turpan-Hami Basin, NW China: A response under the closure of the Paleo-Tethys Ocean	Shuxin QIN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1890
Characteristics and control factors of high poroperm carbonate reservoir of Mishrif Formation in the United Arab Emirates	Beiwei LUO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1892
Influence of multi-stage volcanic events on the Late Cretaceous-Paleogene reservoirs and its geological significance in the northern Central Myanmar Basin	Zengyuan Zhou	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1894
Segmented activity of the Shuntuoguole Low Uplift strike-slip fault zone and its impact on oil and gas charge events: Constraints from calcite veins containing hydrocarbon inclusions	Mengting HANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1895
Multiple hydrocarbon accumulation model around Sangtamu fault zone in Lunnan area, Tarim Basin	GANG PENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1896
Hydrocarbon complex formation model around the periphery of the Lunnan fault zone in the Lunnan area of the Tarim Basin	Maogeng TIAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1898
In-Situ U-Pb Dating and Geochemical Characterization of Multi-Stage Calcite Cementation in the Upper Cretaceous Mishrif Formation, Mesopotamian Basin, Iraq: Constraints on Diagenetic, and Paleo-Oil Filling Events	HUAN WANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1900
Main Controlling Factors on Cambrian Dolomite from the Tarim basin, northwest China: implications for Ultra deep Reservoir	Xuelian YOU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1902
The hydrocarbon charging history and accumulation model of deep buried carbonate reservoirs in Yuqi area, Tarim Basin, Northwestern China	Zhiyi TIAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1904
The basic model and controlling factors of hydrocarbon enrichment in deep buried carbonate reservoirs: A case study of Tuoputai area in the Tarim Basin, Northwest China	Honglei XIE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1906
Geological structure of the Cenozoic strata of the Fergana region in the light of oil and gas prospects	Radjabov SHUKHRAT	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1909
Reunderstanding Of Hydrocarbon Generation Evolution And Hydrocarbon Generation Potential Of Lower Cambrian Source Rocks In Tarim Basin	Shiyang ZHOU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1911
Cretaceous prototype basins, lithofacies paleogeography of Tethys region and their controlling on oil and gas accumulation	Tongfei HUANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1912
Geochemical characteristics and accumulation model of natural gas in the Cenozoic Bohaibay basin	Bo Yang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1914
Influence of tectonic activity on petroleum enrichment：Take organic-rich shale reservoirs for example	xiaoshi LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1915
Ancient alkaline lacustrine formation mechanism and distribution characteristic of Fengcheng Formation in Junggar Basin, Northwestern China	Yunxian FENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1916
Two pulsed activities of the Emeishan large igneous province in southwestern China inferred from dolomite U-Pb geochronology and significance	Di XIAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1918
Discovery, formation, and significance of the basement ancient uplift in the South Yellow Sea Basin	Qingxun WU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1919
Discovery and Geological Significance of Ancient Crystalline Basement in the South Yellow Sea Basin, Eastern China	Jian REN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1920
Discovery of Early Paleozoic “Rifting Troughs” in the South Yellow Sea and Its Significance for Oil and Gas Exploration	Jian REN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1921
New evidence of post Indosinian tectonic evolution in the South Yellow Sea Basin in eastern China	Jian REN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1922
Characteristics and Petroleum Geological Significance of Neoproterozoic Granite in the South Yellow Sea Basin, China	Ying GUO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1923
The relationship between Structural Fracture Development and Hydrocarbon Accumulation in the Foreland Basin under the Tethys Evolution: Examples from the Kuqa Foreland Basin	LI SHANMING	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1925

Title	Presenter	Venue	Start	End	Page
Research on the genesis and characterization methods of non-horizontal fluid surface in oil and gas reservoirs in the Middle East	XIAO DU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1926
Bedding-parallel stylolites as a proxy for the sealing capacity of deep-burial carbonate cap rocks in the Tarim Basin, NW China	Jun WU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1927
S8 Metamorphic fluid mineralization and Ore Remobilization		Session Chair: Scientific Program Committee			
[Keynote] Metamorphic fluids and varieties of orogenic-type gold mineralisation	Andrew TOMKINS	C102	2024-08-29 14:30	2024-08-29 14:50	1948
[Invited] A predictive exploration framework for primary and metamorphosed IOCG and affiliated critical and precious metal deposits in Metasomatic iron and alkali-calcic mineral systems	Jean-Francois MONTREUIL	C102	2024-08-29 14:50	2024-08-29 15:10	1943
The orogenic Mo deposit overprinted by gold mineralization	Nuo LI	C102	2024-08-29 15:10	2024-08-29 15:25	1928
Metamorphic fluids and orogenic-type gold mineralization	Richen Zhong	C102	2024-08-29 15:25	2024-08-29 15:40	1929
The lithium behavior of during prograde metamorphism: implications for optimal crustal sources for mineralization	Ming XIAO	C102	2024-08-29 15:40	2024-08-29 15:55	1931
Protracted gold mineralization in the southern part of the Mozambique Belt: Evidence from the Nanlia and Makorongo prospects, northeastern Mozambique	Manuel NOPEIA	C102	2024-08-29 15:55	2024-08-29 16:10	1939
Orogenic gold mineralization in the Huangling region and its intimate tectonic linkage to the Neoproterozoic orogeny of South China	Huimin WANG	C102	2024-08-29 16:25	2024-08-29 16:40	1937
The polyphase development of gold mineralization in the Kibali gold district: Insights derived from the analysis of pyrite.	Yann Waku Mpaka	C102	2024-08-29 16:40	2024-08-29 16:55	1945
Sulfur and iron isotope constraints on the source of ore-forming materials of the Xiajiadian sediment-hosted gold deposit, China	Xu-Yang LIU	C102	2024-08-29 16:55	2024-08-29 17:10	1946
Base metal mineralisation at Agnigundala Sulphide Belt and deformation stages in Nallamalai Fold Belt, Cuddapah Basin, India	MOHD QAIM RAZA	C102	2024-08-29 17:10	2024-08-29 17:25	1950
Syn-metamorphic remobilization of stratabound Zn and Pb: a case study on the Jiashengpan deposit in northern China	Chang YU	C102	2024-08-29 17:25	2024-08-29 17:40	1941
Metal origin and redistribution of cobalt in the ore-forming fluid of sediment-hosted stratiform Cu-Co deposits: Evidence from geochemistry of sulfides from the Shizishan deposit, SW China	Wenbo LI	C102	2024-08-29 17:40	2024-08-29 17:50	1933
Saline fluids drive Cu mineralization in the Precambrian metasediments in the Trans-North China Orogen	Hong-Rui Fan	C102	2024-08-29 17:50	2024-08-29 18:05	1935
The origin of the pyrite-pyrrhotite veins at Rampura Agucha, India.	Don CHATTERJEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1952
Evolution of the metamorphic fluid in the ca. 1.89 Ga augen orthogneiss from the East European Craton	Laurynas Š ILIAUSKAS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1953
REE and Nb remobilization during post-ore metamorphism of the giant Bayan Obo deposit	Long HAUNG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1955
In situ major, rare earth elements and U-Pb ages of apaite from orogenic Dongkeng gold deposit, Yunkai Massif, South China: implications for mineralization	Guozheng ZHANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1956
Study on the Geochronology and Geochemistry of concealed granite in Tongmukeng Tin deposit in Yunshan, Jiangxi province	MENGQI JIN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1958
Deposit-scale controls of disseminated-type orogenic gold mineralization in high-grade metamorphic turbidites from the Damara belt, Namibia.	Josia Shilunga	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1960
Geochronological and sulfide geochemical evidence for gold mineralization related to post-collisional magmatism in the Wulonggou goldfield of the East Kunlun Orogen, northern Tibet	Qilin WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1961
Fluid Inclusion Characterization of the Quartz Vein in Mineralized Banded Iron Formation of Hiriyur Formation, Dharwar Craton	MANJU SATI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	1962
S9 Promoting best practice in utilization of Geo resources (including Mineral, Water and Energy)		Session Chair: Asim Amitabh Pradhan			
[Keynote] Pyrophyllite as substitute raw material for future Industrial Development in India	ASIM PRADHAN	C104	2024-08-26 16:00	2024-08-26 16:15	1965
Synthesis of Kudremukh Iron Ore Mine Tailings based on Geopolymer Aggregates using Fly ash as Precursor in Construction Industry	Ramaraju H K	C104	2024-08-26 16:15	2024-08-26 16:30	1964
Ultrasonic Leaching: A Green Leaching Technology of Clay-Type Lithium Resources in Salt Lakes	KAISHENG XIA	C104	2024-08-26 16:30	2024-08-26 16:45	1968
UNLOCKING HIDDEN RICHES: NEW METHODS FOR REPURPOSING MINING WASTE IN UZBEKISTAN	Shukhrat Rayimovich SHUKUROV	C104	2024-08-26 16:45	2024-08-26 17:00	1963
Assessing the Impacts of Coal Mining on water quality in the Talcher Region, Angul District, Orissa, India	ARUN NAIK	C104	2024-08-26 17:00	2024-08-26 17:15	1967
The Role of Pyrophyllite in Advanced Materials: A Critical Review of Current Trends	BISWANATH SAHOO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1969
Exploration of geothermal resources by using geophysical method in the north of Changbaishan Mountain	Yan Wu GUAN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	1970
S10 Geo-Resources in Sustainable (Economic) Development		Session Chair: Prabodha Ranjan Sahoo			
[Keynote] Geo-Resources in Sustainable Development	AFIA AKHTAR	C203-204	2024-08-28 08:00	2024-08-28 08:15	1976

Title	Presenter	Venue	Start	End	Page
Geological and technogenic support of the combined exploitation and preservation of the environment during the development of ore deposits.	Marat BITIMBAYEV	C203-204	2024-08-28 08:15	2024-08-28 08:30	1973
Integrated and Multidisciplinary geoscientific mapping of the Limpopo Greenstone Belts, South Africa	Ndivhuwo Cecilia Mukosi	C203-204	2024-08-28 08:30	2024-08-28 08:45	1978
Hydrocarbon prospect in parts of the Nagapattinam sub-basin in the Cauvery Basin, deciphered from the biostratigraphy and source rock characterization	Ashish SARKAR	C203-204	2024-08-28 08:45	2024-08-28 09:00	1971
Push and Pull factors as predictors of entrepreneurial dynamics in artisanal and small-scale mining: a case study on industrial mineral exploitation in South Africa	Ndivhudzannyi Rembuluwani	C203-204	2024-08-28 09:00	2024-08-28 09:15	1975
Effects of foreign direct investment and Belt and Road Initiative on the mining industries in the ASEAN countries	JI WON MOON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	1980
S11 Marine Mineral deposits, science, resources, technology, and environmental challenges, a look to the future		Session Chair: Scientific Program Committee			
The distribution of platinum in ferromanganese crusts and nodules at different depth of the Suda Guyot, Western pacific	Yanhui DONG	C203-204	2024-08-29 08:00	2024-08-29 08:15	1981
Microstratigraphic characterization of mineral diversity of hydrogenetic ferromanganese crusts in the Northwestern Pacific seamounts.	Akira USUI	C203-204	2024-08-29 08:15	2024-08-29 08:30	1983
Seabed mining for a sustainable future	Fani SAKELLARIADOU	C203-204	2024-08-29 08:30	2024-08-29 08:45	1984
Contribution of Multiple Metal Sources to the Formation of Hydrothermal Chimney and Mound in the Mirae-2 Vent Field, Central Indian Ridge	Sun Ki CHOI	C203-204	2024-08-29 08:45	2024-08-29 09:00	1987
Brothers volcano submarine hydrothermal system: upper parts of a porphyry Cu system	Cornel DE RONDE	C203-204	2024-08-29 09:00	2024-08-29 09:15	1988
Morphology-Driven Magnetic Properties in Coastal Ferromanganese Concretions	Joonas WASILJEFF	C203-204	2024-08-29 09:15	2024-08-29 09:30	1990
Morphological Diversity and Its Influence on Geochemical Properties of Ferromanganese Concretions from the Baltic Sea	Joonas VIRTASALO	C203-204	2024-08-29 09:30	2024-08-29 09:45	1992
Mapping and studying the European seabed minerals for sustainable development	Francisco Gonzalez	C203-204	2024-08-29 09:45	2024-08-29 10:00	1993
New Developments of the Seabed Mineral Resources Research on the Norwegian Continental Shelf	Harald Brekke	C203-204	2024-08-29 10:00	2024-08-29 10:15	1995
Towards the first licensing round for seabed minerals on the Norwgian continental shelf - a knowledge-based and stepwise approach	Harald Brekke	C203-204	2024-08-29 10:15	2024-08-29 10:30	1997
In-situ monitoring reveals the vertical stratification characteristics of sediment plume in deep-sea mining	zhihan Fan	C203-204	2024-08-29 10:30	2024-08-29 10:45	1999
A first estimation of resource abundance in the Korea CFC contract area	Gyuha HWANG	C203-204	2024-08-29 10:45	2024-08-29 11:00	1986
In-situ Geotechnical Properties of Abyssal Sediments and Implications for Polymetallic Nodule Mining	Zhenggang LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2000
Quantifying the rare earth element enrichment process of bioapatite in deep-sea REY-rich sediments	Hao Wang	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2002
Hydrothermal activity within seafloor hydrothermal vent fields along the Southwest Indian Ridge	Weifang YANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2004
Potential Impact of Polymetallic Nodules Deep Sea Mining on the World Commodity Markets	Anna LAPTEVA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2005
MARINE PLACER OCCURRENCES AND ASSOCIATED CRITICAL RAW MATERIALS IN RIAS BAIXAS (NW SPAIN)	Francisco González	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2007
Magnetite concentration in serpentinite from the Central Indian Ridge, a tracer of natural H2 formation	Wonnyon KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2009
The comparative analysis of rare earth oxide amount in terrestrial ore deposits and deep-sea sediments	Hyosang KWON	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2010
Depth-dependent variations in paleoceanographic records of the ferromanganese nodules in the Arctic Ocean: High-resolution Raman spectroscopic study	Sangmi LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2011
Baltic Sea ferromanganese concretion growth rates and conditions in laboratory experiment	Renata MAJAMÄKI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2012
Cobalt-rich Ferromanganese Crusts from the Southwest Canary Islands Seamounts: Mineralogy and Geochemistry of Strategic and Critical Elements	Egidio Marino	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2014
S12+S16 Novel approaches to modelling a sustainable and integrated minerals value chain		Session Chair: Lequn ZHANG			
[Keynote] Fundamentals Enabling Integrated Mining Value Chains	Kerry TURNOCK	C104	2024-08-27 08:00	2024-08-27 08:15	2022
Bayesian linear regression with Gaussian mixture likelihood for outlier detection of metal grades	Yufu NIU	C104	2024-08-27 08:15	2024-08-27 08:30	2016
Multiscale variance prediction of metal grade for sortability assessment of bulk ore sorting in Cu deposit	Yufu NIU	C104	2024-08-27 08:30	2024-08-27 08:45	2017
Enhancing named entity recognition in geoscience by using a domain-specific schema	Sandra Paula VIILLACORTA CHAMBI	C104	2024-08-27 08:45	2024-08-27 09:00	2018
Identifying and Quantifying Indirect Trade Flows of Commodities	Jamie BRAINARD	C104	2024-08-27 09:00	2024-08-27 09:15	2019

Title	Presenter	Venue	Start	End	Page
Leveraging Bayesian Hierarchical Models to Mitigate the Impact of Mineral Exploration Uncertainty on the Mineral Value Chain	Lequn ZHANG	C104	2024-08-27 09:15	2024-08-27 09:30	2020
Overview of key Mineral requirements in the era of Intelligent vehicles: taking Software-defined vehicles as an example	Zizhan CHEN	C104	2024-08-27 09:30	2024-08-27 09:45	2023
Quantitative assessment of exploration criteria: A case study from the Yilgarn Craton in Western Australia	Mosayeb KHADEMI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2024
Phosphogypsum stacks from Năvodari (Romania) as secondary resource	Aurora Maruta IANCU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2025
Geochemical fingerprinting of Cobalt and Nickel along the battery value chain: coupled information from trace elements and sulfur isotopes	Yuan Shang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2027
Soil organic matter loss due to anthropogonic activities in settlement area in Forest steppe and Gobi region of Mongolia	Telmen TURMUNKH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2029
S13 Geometallurgy		Session Chair: Raimon Tolosana-Delgado			
Geometallurgy for the Energy Transition	Kathryn Goodenough	C102	2024-08-28 14:30	2024-08-28 14:45	2030
Combination of geostatistical ore grade, RQD, and lithotype models for geometallurgical optimization of a tin deposit	Sylvie RAHARISOLONJANAHARY	C102	2024-08-28 14:45	2024-08-28 15:00	2033
A 2D predictive geometallurgical model of a tailings storage facility	Raimon TOLOSANA-DELGADO	C102	2024-08-28 15:00	2024-08-28 15:15	2034
Machine learning assisted geostatistical modelling of geometallurgical domains	Ute MUELLER	C102	2024-08-28 15:15	2024-08-28 15:30	2035
The processing behaviour of the sphalerites from the Big Syncline deposit, South Africa	Gloria Boikanyo MOTLOBA	C102	2024-08-28 15:30	2024-08-28 15:45	2031
Analyzing Refractory Gold and Deleterious Elements in Historical Witwatersrand Tailings: Implications for Gold Extraction Strategies	Steve Jason CHINGWARU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2036
ROLE OF IN-SITU TECHNIQUES IN IRON ORE MINERAL BENEFICIATION	P V SUNDER RAJU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2037
Forms of ore bodies in the Pirmirab mine	Anzor MAKHAMMATOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2039
Refractory gold ore characterization of the Bonanza-Sandy vein system, Maco Mine, Masara Gold District, Eastern Mindanao, Philippines	JILLIAN AIRA GABO-RATIO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2041
S14 Ore-forming Magmatic Hydrothermal Systems: analysis of source to sink in deposit genesis		Session Chair: Scientific Program Committee			
[Keynote] Facts and myths about orthomagmatic ore deposits	Vadim Kamenetsky	C102	2024-08-27 08:00	2024-08-27 08:15	2067
Controls on the formation of porphyry Mo, Cu and Au deposits in the Qinling Orogenic Belt, central China	Li TANG	C102	2024-08-27 08:15	2024-08-27 08:30	2042
Investigating Chodarchay porphyry-epithermal deposit, NW Iran: Using EPMA and fire-assay minor/trace element data	Majid GHADERI	C102	2024-08-27 08:30	2024-08-27 08:45	2045
Iron-oxide apatite deposits formed by accumulation of magmatic hydrosaline liquids	Xin-Fu ZHAO	C102	2024-08-27 08:45	2024-08-27 09:00	2050
Lead-lead dating reveals Permian granite-induced high-grade niobium mineralization at Bayan Obo	Lan YANG	C102	2024-08-27 09:00	2024-08-27 09:15	2052
Overlapping Alkalic Porphyry Cu-Au and Magnetite-Apatite mineralization in the Iron Mask Batholith, British Columbia, Canada	Andres Felipe GONZALEZ DURAN	C102	2024-08-27 09:15	2024-08-27 09:30	2054
Recycled fluids in magmas of continental-collisional porphyry Cu deposits: Insights from mercury isotopes	Bo XU	C102	2024-08-27 09:30	2024-08-27 09:45	2055
Evolution of pyrite and Cu-Fe-sulphides in the Olympic Dam Cu-U-Au-Ag deposit, South Australia: Evidence from micron-scale EBSD study coupled with LA-ICP-MS analysis	Samuel King	C102	2024-08-27 09:45	2024-08-27 10:00	2058
Oligocene magmato-tectonic events influential in the development of Pb-Zn, Ag and Au mineralization at the Plomosas deposit, southwestern Sierra Madre Occidental, Mexico	Paula MONTOYA LOPERA	C102	2024-08-27 10:00	2024-08-27 10:15	2062
Three-stage niobium mineralization at Bayan Obo, China	Yan YU	C102	2024-08-27 10:15	2024-08-27 10:30	2063
Mineralization and remobilization of heavy rare earth elements in carbonatite rocks: insights from in situ elemental and Sr–S isotopic compositions of sulfate minerals	Si-Qi LIU	C102	2024-08-27 10:30	2024-08-27 10:45	2064
Origin of fluids in the Lancangjiang tin belt, southwestern Yunnan, China: evidence from trace elements and boron isotopic compositions of tourmaline	Yiting ZHU	C102	2024-08-27 10:45	2024-08-27 11:00	2044
[Keynote] Rare metal deposits related to magmatic hydrothermal processes in China	Shao-Yong JIANG	C102	2024-08-27 14:30	2024-08-27 14:45	2048
Cl-rich hydrothermal fluid interaction for scapolite formation in copper deposits of Aravalli-Delhi Fold belt, western India	Prabodha SAHOO	C102	2024-08-27 14:45	2024-08-27 15:00	2061
Investigation of mineralogy, geochemistry, and fluid inclusions of the Ghalozendan iron deposit, Azerbaijan province, NW Iran	Soqra RASTI	C102	2024-08-27 15:00	2024-08-27 15:15	2066
Open System Boiling of Saline Fluids form Salt-rich Ionic Melts: implications for formation of some IOA-IOCG systems	David LENTZ	C102	2024-08-27 15:15	2024-08-27 15:30	2071

Title	Presenter	Venue	Start	End	Page
The role of magmatic sulfide floatation in the formation of seafloor massive sulfide deposits: Insights from the Fatu Kapa volcano in the NW Lau back-arc basin	Jung-Woo PARK	C102	2024-08-27 15:30	2024-08-27 15:45	2070
Paleoarchean volcanogenic massive sulfide (VMS) mineralization in the Nondweni Greenstone Belt, Kaapvaal craton: Direct links to submarine felsic eruptions, not to komatiites	Sebastian TAPPE	C102	2024-08-27 15:45	2024-08-27 16:00	2069
Magmatic initial and saturated water thresholds determine copper endowments: insights from apatite F-Cl-OH compositions	Yingcai SUN	C102	2024-08-27 16:15	2024-08-27 16:30	2068
GENETIC CLASSIFICATION OF SAUSAR GROUP, CENTRAL INDIA: A HOLISTIC APPROACH	SANJOY KUMAR SARKAR	C102	2024-08-27 16:30	2024-08-27 16:45	2043
Magmatic-Hydrothermal Evolution at the Kuh-e Janja Porphyry Cu-Au Deposit, Southeastern Iran: Relative Timing of Hypogene Cu Mineralization from Vapor-Like, Near-Critical Density, Single-Phase Fluids	Majid SOLEYMANI	C102	2024-08-27 16:45	2024-08-27 17:00	2046
FELSIC VOLCANIC HOSTED COPPER-GOLD MINERALIZATION AT MUNDIYAWAS-KHERA AREA, ALWAR BASIN, WESTERN INDIA: A PROSPECTIVE MODEL FOR EXPLORATION	ISRAIL KHAN	C102	2024-08-27 17:00	2024-08-27 17:15	2056
Jurassic-Cretaceous W-Sn polymetallic ore formation and exhumation in South China: Tectonic-magmatic-metallogenic models	Huan LI	C102	2024-08-27 17:15	2024-08-27 17:30	2060
Geological aspects of the Manto type copper deposits in the Sabzevar metallogenic zone, NE Iran	Susan EBRAHIMI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2073
Practical assessment of ore-magmatic systems of Greater Altai	Oxana KUZMINA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2075
Regularities of formation, prognostic criteria of gold-sulphide formation deposits in East Kazakhstan	Marina MIZERNAYA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2076
New evidence for the intrusion-related gold deposit origin of Luanjiahe deposit in Jiaodong Peninsula, China	Xiaofeng Yao	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2078
Caledonian Granites in the Longhua Ni-Co Deposit, South China : Tectonic Setting and Its Relationship with Mineralization	Hejun TANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2080
The critical mineral potential of the Kennedy Igneous Association: Petrogenesis, tectonic setting, and metallogeny	JONGHYUN LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2082
Sulfur and lead isotope geochemistry of granitoid rocks in the Taebaeksan Mineralized District, South Korea	Byeongyong YU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2084
The Genesis of the San Francisco Manganese Deposits, Jalisco, Mexico: Geological Insights and Mineralogical Signatures	Genesis RAMOS GARCIA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2085
Cathodoluminescence, trace element and fluid inclusion studies of the ginguro-bearing crustiform veins in the Hokuryu Ag-Au deposit, Hokkaido, Japan	Omar SOBERANO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2087
Hyper-enrichment of gold via quartz fracturing and growth of polymetallic melt droplets: example from the Xiaoqinling lode gold district, central China	Wei Jian	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2088
Fluid Evolution of the Wunugutushan Porphyry Copper-Molybdenum Deposit in Inner Mongolia: Insights from Quartz Fluid Inclusions and Muscovite Compositional Studies	Xiangkai CHU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2089
New geochronological constraints on the giant Nurkazgan porphyry Cu-Au deposit, Central Kazakhstan	Haoxuan FENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2091
S15 Lithocaps and high sulfidation epithermal deposits		Session Chair: Peter Hollings			
Geology, alteration and mineralization of the Pemberton Hills porphyry system, Canada: anatomy of a lithocap	Pete HOLLINGS	C102	2024-08-26 16:30	2024-08-26 16:45	2093
Nature and Characteristics of Gold Deposit of Bhitar Dari Area of Gorumahisani-Badampahar Greenstone Belt of Iron Ore Group, East Singhbhum District, Jharkhand, India.	PANKAJ KUMAR	C102	2024-08-26 16:45	2024-08-26 17:00	2095
The formation of gold-rich goethite and hematite in an epithermal gold deposit	Feng-Xia HUANG	C102	2024-08-26 17:00	2024-08-26 17:15	2097
Alunite and pyrite mineral chemistry vectoring to high-grade Au-Ag orebodies associated with the Martabe lithocap in Sumatra arc, Indonesia	Wei Hong	C102	2024-08-26 17:15	2024-08-26 17:30	2099
S17 Rare criticals metal geochemistry and mineral deposits		Session Chair: David Lentz			
Extreme low-T fractionation of felsic magmas and implications for rare-metal deposit genesis: analysis of regional thermal considerations and internal high heat production	David LENTZ	C102	2024-08-28 16:00	2024-08-28 16:15	2110
South African coal and coal by-products as potential alternative sources for rare earth elements: A case study of the Ermelo, Soutpansberg, Tuli, Utrecht and Waterberg coalfields	Christopher Baiyegunhi	C102	2024-08-28 16:15	2024-08-28 16:30	2101
The volcanic-hosted beryllium deposits in eastern China: Tectonic setting, Ages and Metallogenic potential	Xiaofeng LI	C102	2024-08-28 16:30	2024-08-28 16:45	2102
The chemical composition of helvine-group minerals and implications for the genesis of beryllium deposit: cases studies from Dawan, Qidushan and Taoxikeng deposits, southeast China	Yiting ZHU	C102	2024-08-28 16:45	2024-08-28 17:00	2103
Li-Rb-Cs mineraliztion of granite-pegmatite in the Gyirong-Nyalam region, Tibet and its significance	Fangyang HU	C102	2024-08-28 17:00	2024-08-28 17:15	2104
A preliminary study on the beryllium mineralization in the southern Great Xing'an Range, northeastern China	Yu-Sheng Zhu	C102	2024-08-28 17:15	2024-08-28 17:30	2105

Title	Presenter	Venue	Start	End	Page
Volcanic-hosted hydrothermal rare earth element (REE) mineralisation, West Musgrave Province, Australia	Ben James Kimpton	C102	2024-08-28 17:30	2024-08-28 17:45	2112
Rare metal (REE, Nb, Ta) deposits hosted by carbonatite and alkaline complexes: A Canadian perspective	Anne-Aurélie Sappin	C102	2024-08-28 17:45	2024-08-28 18:00	2108
Rare Metals in Coals of Far East of Russian: Concentrations & Resources in Coal deposits	VLADIMIR ILICH VYALOV	C102	2024-08-28 18:00	2024-08-28 18:15	2106
In-situ U-Pb Dating of Apatite in Heima Pegmatite-hosted Lithium Deposit, West Yunnan	Yong YU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2113
Mineralogy of the REE-rich carbonatite complexes in Khotgor, South Mongolia	Bingbing GAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2115
Zircon and cassiterite U-Pb geochronology, Hf isotopes and geochemistry characteristics of Xianglushan rubidium-rich granite complex and its geological significance, northeast Guangxi , China	Yupeng HUO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2117
Allanite crystallization inhibits economic rare earth element mineralization in carbonatites.	SOURAV BHATTACHARJEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2119
Modification of magmatic-hydrothermal tin deposits by ductile shearing: Example of the Jiufeng and Nandaoao tin deposits of northern Guangxi, south China	ZuoHai FENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2121
THE ZONE OF JUNCTION OF OIL AND GAS BEARING STRUCTURES AND URANIUM PROVINCES	Rakhimjan TURSUNMETOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2123
Beryl chemistry as a compositional framework for prospecting of rare-metal pegmatites in Nepal Himalaya	SUSHMITA BHANDARI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2125
S18 Hydrodynamic studies of mineralization		Session Chair: Scientific Program Committee			
Cycling of Uranium (U)-polymetals in Earth System and its Effect on Mineral Resources and Environment	Deru XU	C104	2024-08-27 14:30	2024-08-27 14:45	2126
Hydrodynamic relationships between shallow and deep parts of mineralization systems and implications for deep mineral exploration	Guoxiang Chi	C104	2024-08-27 14:45	2024-08-27 15:00	2128
Hydrodynamics of the Xiangshan volcanic-type uranium deposits in Jiangxi Province, South China	Zenghua LI	C104	2024-08-27 15:00	2024-08-27 15:15	2130
Genetic association between carbonates and gold precipitation	Teng Deng	C104	2024-08-27 15:15	2024-08-27 15:30	2131
Numerical modeling of the formation of ore shell by ore-forming materials enrichment in porphyry copper deposits	Changhua XIE	C104	2024-08-27 15:30	2024-08-27 15:45	2133
The influence of basin fluid activity on the mineralization process of sandstone-type uranium deposits	Taping He	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2134
S19 Mineralogy and Ore deposits in Alp-Himalaya belt		Session Chair: Shohreh Hassanpour			
Low-crustal juvenility and continental-slab shallow subduction control the formation of post-collisional porphyry Cu systems in east Tibet	Zengqian HOU	C203-204	2024-08-29 14:30	2024-08-29 14:45	2137
Deep process and lithospheric architectural control of Cu-REE mineralization in the Gangdese and Sanjiang collisional belts	Rui WANG	C203-204	2024-08-29 14:45	2024-08-29 15:00	2140
Porphyry Copper Deposits Main Characteristics in Iran	Maryam AHANKOUB	C203-204	2024-08-29 15:00	2024-08-29 15:15	2141
The Characteristics and Origin of Barite in the Giant Mehdiabad Zn–Pb–Ba Deposit, Iran	Yingchao LIU	C203-204	2024-08-29 15:15	2024-08-29 15:30	2135
W-Mo porphyry deposit Ochtiná-Rochovce (Western Carpathians, Slovakia) - lithological and mineralogical characterization	Peter Koděra	C203-204	2024-08-29 15:30	2024-08-29 15:45	2138
S20 Metallogeny and Geodynamics of East and SE Asia		Session Chair: Khin Zaw			
Multiple mineralization and geodynamics of the Nanyangtian tungsten deposit, SW China: Constraints from structural deformation and geochronology	Da ZHANG	C102	2024-08-28 08:00	2024-08-28 08:15	2149
Copper skarn mineralization related to reduced monzodioritic magma at the Huanren deposit, northeastern China	Hegen Ouyang	C102	2024-08-28 08:15	2024-08-28 08:30	2147
Gold Deposits of the Jiaodong Peninsula, Eastern China	Kunfeng QIU	C102	2024-08-28 08:30	2024-08-28 08:45	2151
Magmatic history in the Suyoc prospect: Implications to hydrothermal mineralization in the Mankayan Mineral District, north Luzon, Philippines	JILLIAN AIRA GABO-RATIO	C102	2024-08-28 08:45	2024-08-28 09:00	2157
Geodynamics of Late Mesozoic giant decratonization-related gold mineralization in the North China Craton	Jin-Hui YANG	C102	2024-08-28 09:00	2024-08-28 09:15	2146
Bimodal volcanism and massive sulfide deposition in the mid-Miocene Hokuroku Rift of NE Japan	Andrea Agangi	C102	2024-08-28 09:15	2024-08-28 09:30	2158
Role of chalcophile element fertility in the formation of post-collisional porphyry Cu deposits in the eastern Tethyan domain	Hongda Hao	C102	2024-08-28 09:30	2024-08-28 09:45	2161
Magma fertility of the Wuntho–Popa arc belt: implication for porphyry Cu mineralization in Myanmar	Jing-Jing Zhu	C102	2024-08-28 09:45	2024-08-28 10:00	2160
Eruption Style, Mineralization and Geohazard of Mt Popa Volcano, central Myanmar	Khin ZAW	C102	2024-08-28 10:00	2024-08-28 10:15	2144
Geodynamic settings of formation and metallogeny of gold in the Altai-Sayan folded area (Southern Siberia)	Alexandr CHERNYKH	C102	2024-08-28 10:15	2024-08-28 10:30	2142
Exploration Potential of Antimony Deposits in Myanmar: Insights from Fluid and Stable Isotope Geochemistry of the Lyhamyar Sb Deposit, Eastern Myanmar	Aung Min OO	C102	2024-08-28 10:30	2024-08-28 10:45	2152

Title	Presenter	Venue	Start	End	Page
Mineralogy, Geochemistry, and Origin of Green Jasper in Northeastern Region of Cambodia	Seang Sirisokha	C102	2024-08-28 10:45	2024-08-28 11:00	2154
Characteristics and Timing of Migmatite Structures Exposed along the Kyaikkhami Beach area, Thanbyuzayat Township, Mon State, southern Myanmar	Zin Mar OO	C102	2024-08-28 11:00	2024-08-28 11:15	2155
Origin of pegmatite-related gem deposits, northwestern part of Pyetkaywe Batholith, Myittha Townships, Mandalay Division, Myanmar	Yin Yin MYINT	C102	2024-08-28 11:15	2024-08-28 11:30	2156
U–Pb and Hf-isotope analysis of zircons and Molybdenite Re-Os Dating in Gao'aobei Tungsten-molybdenum Ore, Southern Hunan Province , South China	Yanbin WANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2162
U-Pb geochronology, trace elements and Sr-Nd isotope geochemistry of the gold deposit in the Rangnim Massif, North Korea: a model for hydrothermal ore genesis	LEI XU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2163
Biogenic mediated pyrite formation in the Shinyemi Skarn Fe polymetallic deposit, South Korea	Naing Aung KHANT	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2165
Geochemical characteristics of antimony and tungsten mineralization of the Doi Ngom deposit, northern Thailand	Karn Phountong	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2166
Linking two types of breccia bodies to sedimentary rock-hosted stratiform copper (SSC) and iron oxide-copper-gold (IOCG) deposits in the Kangdian metallogenic belt, SW China	Xue-Qing YIN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2167
Robust age constraints on the Carlin-type gold and Skarn-type W deposits in the Youjiang basin of China: Implications for their genetic linkage and future exploration	WEI GAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2168
Metal sources of sediment-hosted antimony deposits: Evidence from antimony isotopes	Shanling FU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2169
S21 Uranium, thorium and related atomic energy minerals resources		Session Chair: Deepak Kumar Sinha			
[Keynote] Unusual multi-metallic uranium deposits in India: Their potentialities.	DEEPAK SINHA	C102	2024-08-29 08:00	2024-08-29 08:30	2171
Analysis and prediction of supply guarantee for the development of world nuclear power	SONG Jiye	C102	2024-08-29 08:30	2024-08-29 08:45	2185
A new exudation metallogenic model for uranium deposit in the red-mottled sedimentary sandstone system in northern basins of China	Ziying LI	C102	2024-08-29 08:45	2024-08-29 09:00	2174
Late Cretaceous-Cenozoic tectonic-sedimentary evolution and U-enrichment in the southern Songliao Basin	Shaoyi WANG	C102	2024-08-29 09:00	2024-08-29 09:15	2182
Trapping of uranium by organic matter within sandstones during mineralization process: A case study from the Shuanglong uranium deposit, China	Fan Zhang	C102	2024-08-29 09:15	2024-08-29 09:30	2170
Trans-strata mineralization of sandstone-hosted uranium deposits triggered by neotectonics	Yinhang CHENG	C102	2024-08-29 09:30	2024-08-29 09:45	2183
Sandstone-type uranium deposits hosted in the aeolian sandstone: Taking an example of the Pengyang-Jingchuan deposit in the Ordos Basin, China	YIN CHEN	C102	2024-08-29 10:00	2024-08-29 10:15	2172
Determination of radon exhalation rate of uranium ore samples from sandstone-hosted uranium deposits	Nanping WANG	C102	2024-08-29 10:15	2024-08-29 10:30	2184
Analysis on Uranium Metallogenic Conditions and Prospect Review of the Langka-Daladi Aera in Eastern Part of Southern Margin of Yili Basin, North China	SONG JI Jiye	C102	2024-08-29 10:30	2024-08-29 10:45	2176
Genesis of high-grade uranium deposits in Motianling Neoproterozoic granites from northern Guangxi Province, South China: Constraints from in situ micro-chronology, sulfur isotope and trace elements analysis	Yongjian WANG	C102	2024-08-29 10:45	2024-08-29 11:00	2177
Uranium mineral systems in Brazil	Hugo POLO	C102	2024-08-29 11:00	2024-08-29 11:15	2180
Uranium mineralization age constraint by indirect dating of syn-ore gangue minerals: a case study from a Na-metasomatite uranium deposit in Northwest China	Jun ZHONG	C102	2024-08-29 11:15	2024-08-29 11:30	2179
Thorium and Uranium ore occurrences of Georgia (The Caucasus): A comparative analysis and Prospects	Avtandil OKROSTSVARIDZE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2186
Occurrence and geochemical characteristics of uraniferous soil in Maninsan area, South Korea	Jinah Lim	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2188
Mineralogy of residual and redeposited uranium in the boreholes of in-situ leaching uranium mining	Anna Vladimirovna SASHCHENKO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2189
New frontiers of multi-scale uranium exploration in Brazil. Case studies: Rio Cristalino and Itataia regions.	Isabelle Cavalcanti Corrêa de Oliveira SERAFIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2191
Research on the verification method of weak information of airborne gamma spectrometry for sandstone-type uranium exploration	LIANCHENG SHI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2193
A Study on the Uranium-Radium Equilibrium Coefficient of Barun Sandstone-Hosted Uranium Deposit, Inner Mongolia	Aimin PENG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2195

Title	Presenter	Venue	Start	End	Page
Types and spatiotemporal distribution characteristics of uranium deposits in China	Yuqi CAI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2196
S22 Iron Mineral System		Session Chair: Scientific Program Committee			
BIF-hosted iron ore: A mineral system review	Steffen HAGEMANN	C203-204	2024-08-29 16:00	2024-08-29 16:15	2202
The complex origin of the Proterozoic Varena Iron Ore deposit in the SW East European Craton, southern Lithuania: implications from microstructures, mineral chemistry and isotope study	Grazina SKRIDLAITE	C203-204	2024-08-29 16:15	2024-08-29 16:30	2197
Mineralogy, mineral chemistry, and Fe-O isotope geochemistry of IOA-style mineralization and wall-rock alteration at the Yangyang deposit in the central-eastern Korean Peninsula	Heonkyung IM	C203-204	2024-08-29 16:30	2024-08-29 16:45	2199
Timing of iron skarn mineralization by U-Pb dating of Ca-Fe garnets	Ekaterina SALNIKOVA	C203-204	2024-08-29 16:45	2024-08-29 17:00	2201
S23 Navigating the Path to the Green Transition: Balancing Resource Extraction and Environmental Stewardship		Session Chair: Christopher Keane			
[Keynote] Envisioning 2050: Strategic Scenarios for the Global Raw Materials Landscape	Christopher KEANE	C203-204	2024-08-30 08:00	2024-08-30 08:15	2205
Mining to meet the challenge of Net Zero	David MANNING	C203-204	2024-08-30 08:15	2024-08-30 08:30	2206
Mechanochemical processing of silicate rocks to trap CO2	Zoe SHIPTON	C203-204	2024-08-30 08:30	2024-08-30 08:45	2212
High-tech metals are key elements for future technologies – What are the challenges and how are their global market situations ?	Volker STEINBACH	C203-204	2024-08-30 08:45	2024-08-30 09:00	2204
Critical raw materials extraction in environmentally protected areas	Vitor Correia	C203-204	2024-08-30 09:00	2024-08-30 09:15	2208
Ukrainian Salt Sector: Strategy for Post-War Recovery, Sustainable Development, and Advancement of Salt Resources as Input in Green Transition Technologies	Larysa BOSEVSKA	C203-204	2024-08-30 09:15	2024-08-30 09:30	2210
Mineral resource abundance index: Towards responsible cosmetic ingredients and use of minerals in downstream industries	Nicolas CHARLES	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2213
S24+S6 HTHP geofluid-rock interactions, mass circulation and deep hydrocarbons in sedimentary basins		Session Chair: Scientific Program Committee			
[Keynote] Mixing processes and patterns of fluids in alkane-CO2-water systems under high temperature and high pressure—Microscopic visual physical thermal simulations and molecular dynamics simulations	Guanghui YUAN	C203-204	2024-08-30 09:30	2024-08-30 09:45	2219
Diagenetic Processes and Low-Permeability Tightening Mechanisms of Reservoirs in the Paleogene Deep Layers under High-Temperature and High-Variability Conditions in the Baiyun Sag, Pearl River Mouth Basin	Xiaoyang Zhao	C203-204	2024-08-30 09:45	2024-08-30 10:00	2220
Lamina-scale diagenetic mass transfer in lacustrine organic-rich shales and the impacts on shale oil reservoir formation	Kelai Xi	C203-204	2024-08-30 10:00	2024-08-30 10:15	2218
Fluid-rock interaction of deep hydrothermal fluids and its reservoir response in carbonate rocks: A case study from the Ordovician in the Tarim Basin	Jian WANG	C203-204	2024-08-30 10:15	2024-08-30 10:30	2226
Research on exploration technology of sandstone-type uranium deposits in Erlian Basin based on airborne magnetic, aeroradiomeairborne gamma spectrometry and gravity surveys	LIANCHENG SHI	C203-204	2024-08-30 10:30	2024-08-30 10:45	2224
Origin of carbonate cements and their control on sandstone reservoir quality in the First Member of the Eocene Shahejie Formation, Bohai Sea, East China	Xiaojun PANG	C203-204	2024-08-30 10:45	2024-08-30 11:00	2215
Influence of diagenetic fluid on glutenite reservoirs: a case study of the Junggar Basin, China	Zhiguo MAO	C203-204	2024-08-30 11:00	2024-08-30 11:15	2217
Oxidation of hydrocarbons in deep strata of continental sedimentary basins: Evidences, mechanism, and geological implications	Xun KANG	C203-204	2024-08-30 11:15	2024-08-30 11:30	2222
The influence of microscopic petrological characteristics on fracability of tight sandstone in the Yanchang Formation of the Longdong Area, China	Xiaoming SHI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2228
Impact of CO2 influx on sandstone reservoir quality: A case study of the Quantou Formation, southern Songliao Basin, China	Zheng Cao	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2229
Characteristics and origin of deep and ultra-deep high-quality clastic reservoirs in the steep slope zone of the Minfeng sub-sag, Dongying Sag, China	Jiageng LIU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2230
Study on the Main Controlling Factors of Effective Reservoirs in Tight Beach Bar Sand Oil Reservoirs in the Dongying Depression	Huafeng ZHANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2232
Mixing processes of the oil-water-CO2 systems in different fluid phases: Insights to CO2 sequestration in depleted hydrocarbon reservoirs	Zihao JIN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2234
Study on Diagenetic Fluids and Reservoir Evolution of Near Source Glutenite Reservoirs, Bozhong Depression Paleogene	Jin HU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2236
Synergistic diagenesis and shale oil enrichment patterns in the Chang 73 sub-member of Triassic Yanchang Formation in the Ordos Basin	Xiaobing NIU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2238
The impact of burial dissolution on the development of ultra-deep fault-controlled carbonate reservoirs: Insights from high-temperature and high-pressure dissolution kinetic simulation	Xiaolin TAN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2239

Title	Presenter	Venue	Start	End	Page
The Stability of the CO2-H2O-Dawsonite-Bearing Sandstone Reaction System: Experimental Study And Thermodynamic Simulation	Kaining WANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2240
The use of Airborne Geophysics in Mineral Exploration	Alla DIAW	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2242
Superimposed transformation by multiple types of fluids during diagenesis in ultra-deep carbonate reservoirs	Leilei Yang	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2244
S25 Advances and Innovations in Uranium Exploration and Resource Evaluation. (A special session in memory of the late Dr. K. Kyser)		Session Chair: Adrienne Hanly			
[Keynote] IAEA activities supporting capacity building and innovations in uranium resources, processing and mining	Adrienne Hanly	C104	2024-08-27 16:00	2024-08-27 16:30	2251
Significant Progresses and Prospects in Innovation of Uranium Geology in China Since 2000	Mingkuan QIN	C104	2024-08-27 16:30	2024-08-27 16:45	2249
Progress in the extraction and integration of uranium mineralization information in the basin	Yu RENG-AN	C104	2024-08-27 16:45	2024-08-27 17:00	2250
The relationship between Meso–Cenozoic tectonic-fluid evolution and sandstone type uranium mineralization in Kuqa Depression, Tarim Basin, western China	NIAN LIU	C104	2024-08-27 17:00	2024-08-27 17:15	2248
The role of transient processes in the generation of giant uranium deposits	Patrick LEDRU	C104	2024-08-27 17:15	2024-08-27 17:30	2246
S26 General Topics		Session Chair: Scientific Program Committee			
Ore mineralization of some gold deposits of Mongolia: Gold mineralization linking to the crystal forms	MUNGUNTULGA PUREVSUREN	C203-204	2024-08-30 13:45	2024-08-30 14:00	2252
Nanoparticles Observed by TEM from Gold, Copper-Nickel and Silver Deposits and and Their Significance for Mineral Exploration in Covered Terrains	Bimin ZHANG	C203-204	2024-08-30 14:00	2024-08-30 14:15	2263
Sources of dissolved solutes and physico-chemical conditions of fluorite (± barite) mineralisation at Dongargaon, India: Constraints from geochemical study of bulk rock and hydrothermal minerals	PANKAJ VAIDYA	C203-204	2024-08-30 14:15	2024-08-30 14:30	2259
Reinterpretation and 3D visualization of Pine Creek Orogen (NT, Australia)	Gemma Mitjanas	C203-204	2024-08-30 14:30	2024-08-30 14:45	2258
Analysis of the Safety Situation of Potash Resources in China and Suggestions for Global Cooperation	YAN ZHANG	C203-204	2024-08-30 14:45	2024-08-30 15:00	2264
Ultramafic-Hosted Magnesite Deposits in Southern Peninsular India: Spectral and Stable Isotopic Insights	HARITHA A	C203-204	2024-08-30 15:00	2024-08-30 15:15	2261
The role of mineral-related industries in Chinese industrial pattern	Weidong LI	C203-204	2024-08-30 15:15	2024-08-30 15:30	2253
Simulation Analysis of Supply Crisis Propagation Based on Global Nickel Industry Chain	Xingxing WANG	C203-204	2024-08-30 15:30	2024-08-30 15:45	2254
GEOLOGICAL-GEOCHEMICAL MODEL OF THE DAUGYZ GOLD DEPOSIT (SOUTHERN TIEN SHAN, CENTRAL KYZYLKUM)	JAKHONGIR MOVLANOV	C203-204	2024-08-30 15:45	2024-08-30 16:00	2255
Research on the impact of global mineral trade structure on national economy	XIAN XI	C203-204	2024-08-30 16:00	2024-08-30 16:15	2257
First row transition metals deportment in Cretaceous karst bauxite: the case of the southern Italy and Sardinia Island deposits	Giovanni MONGELLI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2265
Potential Natural Hazards of Mineral Facility and Effect of Mineral Production Using Geospatial Data for Asia-Pacific Region	Jaewon CHUNG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2267
The impact of oil decoupling between EU and Russia on the pattern of global oil trade under the Russia-Ukraine military conflict	Xiu WANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2268
Copper-Gold Mineralization in a Covered Basement Complex of North Delhi Terrane, Rajasthan: Implication towards Mineral Potential of Basement Rocks	Arindam MISRA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2269
Genesis of Gold mineralization in Sonakhan Greenstone Belt, Bastar Craton, India: constraints with fluid inclusion studies.	Sathyavani C	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2271
Combined Study of Gold-Bearing Arsenopyrite of Orogenic Gold Deposits: High Resolution 3D X-ray Computed Tomography, LA-ICP-MS and EMPA Analyses	Evgeny NAUMOV	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2273
The National Geological Plan of Angola (PLANAGEO)	José GARCÍA LOBÓN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2275
Mineral chemistry of tourmaline associated with the Zawar Zn-Pb deposit, Rajasthan, India	ARKODEEP SENGUPTA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2276
Development Characteristics and Preservation Mechanism of Primary Pores in Ultra-deep Cretaceous Reservoirs in the Kelasu Structural Belt of the Kuqa Depression	Shilong LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2277
Characteristics of Source Rocks and Formation of Reservoir Bitumen in Yinchuan Graben, Ordos Basin, China	Qingmeng FU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2279
Cross-layer propagation of natural fractures in finely laminated shale	huawei LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2280
Fluid migration through an intensively overpressured diapir in the Yinggehai Basin, South China Sea	zhifeng GUO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2281
New Re-Os molybdenite age for the Erdenetiin Ovoo Cu-Mo ore field, North Mongolia	Baatar MUNKHTSENGEL	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2282
Element Distribution and REE Dispersal in Sandstone-Hosted Copper Mineralization within Oligo-Miocene Strata, NE Iran: Insights from Lithostratigraphy and Mineralogy	MOSTAFA FEIZ	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2284

Title	Presenter	Venue	Start	End	Page
Relationship between vegetation canopy and selected ore bodies of Iran	Shahindokht ABOLMAALI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2286
T13 Mineralogy					
S2 Gemstone and Geological Formation		Session Chair: Chakkaphan SUTTHIRAT, Youngchool Kim			
A New Approach for Detecting Heat Treatment of Sapphire	Teerarat PLUTHAMETWISUTE	C104	2024-08-28 08:00	2024-08-28 08:15	2287
Ageing Characterization and Origin Traceability of archaeological amber artifacts via FTIR spectroscopy and Pyrolysis-gas chromatography/mass spectrometry (Py-GC/MS)	Yan LI	C104	2024-08-28 08:15	2024-08-28 08:30	2290
Chemical Composition and origin of color in Black and Black Cyan Nephrite from Margou Deposit, Qiemo county, Xinjiang, China	Ting FANG	C104	2024-08-28 08:30	2024-08-28 08:45	2292
The Structure of Natural Opal-A: An Insight through Synchrotron X-ray Diffraction and Pair Distribution Function Analysis	Seungyeol LEE	C104	2024-08-28 08:45	2024-08-28 09:00	2293
Fast identification of imitation pearls against cultured pearls using hyper near-infrared spectroscopy	JINHEE LEE	C104	2024-08-28 09:00	2024-08-28 09:15	2296
Unusual mixed characteristics of sapphires from magmatic deposits in Muling, Northeast China	Yimiao Liu	C104	2024-08-28 09:15	2024-08-28 09:30	2297
Beyond Jewelry: The Quantum Realm of Diamonds	Hyunmin CHOI	C104	2024-08-28 09:30	2024-08-28 09:45	2298
The Special Color Effect in “Chameleon” Amber and its main Fluorescence Component	Yan LI	C104	2024-08-28 09:45	2024-08-28 10:00	2299
Chemistry defect, the clue to understand colorations in gem corundum varieties and more	Pornsawat WATHANAKUL	C104	2024-08-28 10:00	2024-08-28 10:15	2302
Unusual Synthetic Overgrowth on Natural Rose-Quartz Crystal Aggregate	Thanapong LHUAAMPORN	C104	2024-08-28 10:15	2024-08-28 10:30	2295
The color center of beryllium-treated blue sapphires	Natthapong MONARUMIT	C104	2024-08-28 10:30	2024-08-28 10:45	2301
Observation of characteristics of synthetic diamonds in ultraviolet illuminating	EUNOK JO	C104	2024-08-28 10:45	2024-08-28 11:00	2300
ANCIENT NEPHRITE QUARRY NEWLY DISCOVERED: CHARACTERIZATION OF NEPHRITE FROM SANWEI MOUNTAIN, GANSU PROVINCE, WESTERN CHINA	YUE SU	C104	2024-08-28 11:00	2024-08-28 11:15	2289
Comprehensive Spectral and Chemical Characterization of Amber from Xixia, Henan Province	Yan LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2304
BLUE SAPPHIRE GENESIS AND CHARACTERIZATION OF BAW MAR GEM DEPOSIT, MOGOK TOWNSHIP, MYANMAR	Arkar Moe MYINT	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2306
Mahan Carnelian beads production techniques and sociopolitical significance of long-distance trade	JINA HEO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2307
Hauyne of an Unusually Rare Green Color	BUDSABAKORN SRISATAPORN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2308
Transparent and Bright Greenish-Blue Sodalite: An Extremely Rare Gemstone	Kannatee FUEANGAKSORN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2310
Influence of Electron Radiation on Colour Modification and Colour Stability of Pink Sapphires: A Preliminary Study	WARATCHANOK SUWANMANEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2311
S3+S1+S5 Geochemistry, Isotopic Characteristics, and Geochronology of Gem deposits		Session Chair: Scientific Program Committee			
Baddeleyite SK10-2 and Rutile KNW: Two natural reference materials for microbeam U-Pb geochronology	Shitou WU	C104	2024-08-29 08:00	2024-08-29 08:15	2312
Agrominerals and food security in Africa	Olugbenga Okunlola	C104	2024-08-29 08:15	2024-08-29 08:30	2313
Trace element in blue sapphire: Challenge or potential of element analyses by LA-ICP-TOF-MS for origin determination?	Wei ZHOU	C104	2024-08-29 08:30	2024-08-29 08:45	2317
Geochronology of diamond formation in the mantle and its relation to geodynamics	Felix Kaminsky	C104	2024-08-29 08:45	2024-08-29 09:00	2315
Three natural reference materials for in situ andradite U–Pb geochronology	Yueheng Yueheng YANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2319
Different origins of garnet in high-grade metamorphic rocks	Qiong-Xia XIA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2320
Paragenesis of Alteration/Zoning in Meta-Sedimentary Chromite from the Singhbhum Craton, Eastern India.	Asish Kumar DAS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2321
Petrological and structural characterisation controlling gold mineralization in the northern part of the Kon Tum massif, Central Highlands of Vietnam	THÀNH VŨ-TIẾN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2322
Age of the South Ural mines: U-Pb ID-TIMS garnet dating	Yulia PLOTKINA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2323
Review on geochemical, metallogenesis, and geodynamic studies for the origin and mineralisation potential of rare metal pegmatites of Côte d'Ivoire (West Africa).	Felix Oufouet KONAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2325
MINERALOGICAL FEATURES OF GOLD ORES OF THE SARYJAY AREA (BUKANTOU MOUNTAINS, CENTRAL KYZYLKUM)	SHOKHIDA SAMANDAROVA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2327

Title	Presenter	Venue	Start	End	Page
The origin of olivine in kimberlite inferred from variably compositional zoning in kimberlite from Karowe mine, Botswana	Wentao Cao	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2328
Enhancing Ceramic Quality through Mineralogical Adjustments in Highly Silicic Clays: A Case Study from Brunei Darussalam	Elena IFANDI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2329
S4 Environmental Mineralogy: From Understanding To Application		Session Chair: Scientific Program Committee			
Molecular-scale understanding of the sorption structure and reactivity of heavy metals at mineral-water interfaces		C104	2024-08-28 14:30	2024-08-28 14:45	2341
Understanding the facet-mediated molecular-level interactions between antimony (III and V) oxyanions and boehmite (γ-AlOOH) based on the physicochemical properties of mineral		C104	2024-08-28 14:45	2024-08-28 15:00	2331
Atomistic structure models of nanocrystalline vernadite mineral		C104	2024-08-28 15:00	2024-08-28 15:15	2333
Effect of Ca-containing byproducts generated during interzeolite transformation on the sequestration and release of Cs		C104	2024-08-28 15:15	2024-08-28 15:30	2334
On the crystal structures and thermodynamics of Sr-bearing calcite		C104	2024-08-28 15:30	2024-08-28 15:45	2336
Sorption of thorium, cesium, and lead onto secondary iron minerals and clay minerals		C104	2024-08-28 15:45	2024-08-28 16:00	2337
Abiotic Catalytic Reaction Dominance in Manganese Removal from an Acidic Mine Water		C104	2024-08-28 16:00	2024-08-28 16:15	2339
Efficient Seawater Splitting with Ni-based Oxyhydroxide Catalysts: A Computational Perspective		C104	2024-08-28 16:15	2024-08-28 16:30	2343
Replacement of Calcium Carbonate ($CaCO_3$) Polymorphs by Cerussite ($PbCO_3$)		C104	2024-08-28 16:30	2024-08-28 16:45	2344
Solid Substrate-Induced Variations in the Heterogeneous Formation of Mn Solid Phases		C104	2024-08-28 16:45	2024-08-28 17:00	2345
Insights into the Origin of Pyrite in the Sediments of Brunei Darussalam		C104	2024-08-28 17:00	2024-08-28 17:15	2346
Characterization of Phosphate in Total Suspended Particles (TSP) at Seoul, South Korea	Seungsoo LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2347
Effects of different tunnel cations on adsorption, occurrence, and mobility of water in palygorskite	Jinhong ZHOU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2349
Investigation of characteristic heavy metal contamination of roadside dusts in Daejeon, Korea: Impacts of car tire, brake pad and traffic paint on the elevated levels of Zn, Cu, Sb and Cr	Seon Yong LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2350
Molecular simulations of CO_2 and H_2 insertion into palygorskite	Juhyeok KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2352
Mineralogical Study of Bentonite Transformation Under High Temperatures	SeEun CHANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2353
Laboratory-scale reproduction of Smectite-Illite transformation using Bentonil-WRK	Mi Rae KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2354
The Alteration of Fault Gouge with Supercritical CO_2: Changes in Fault Stability by Carbon Sequestration	Yuna LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2355
S6 Silicate melts, magmas, and non-crystalline earth materials in Earth and Planetary Surfaces and Interior		Session Chair: Razvan CARACAS, Sung Keun LEE			
[Invited] Planetary melts: constraining viscosity via the glass transition.	Donald B. Dingwell	C104	2024-08-29 14:30	2024-08-29 14:45	2364
[Invited] How do transition elements influence viscosity of glasses, melts and lavas?	Daniel R. NEUVILLE	C104	2024-08-29 14:45	2024-08-29 15:00	2358
An improved structural model of silicate melts and magmas probed with NMR spectroscopy: implications for planetary sciences	Jeongjae LEE	C104	2024-08-29 15:00	2024-08-29 15:15	2357
Probing the short- to medium range structures of simplified Ti-rich lunar glass using NMR spectroscopy: implication for lunar mantle dynamics	Elias EL GHAZAOUI	C104	2024-08-29 15:15	2024-08-29 15:30	2361
The pyrolite melts of the early Earth: structure, compressibility, viscosity, volatile content	Razvan CARACAS	C104	2024-08-29 15:30	2024-08-29 15:45	2360
[Invited] A multiscale simulation study of supercritical geofluids	Xiandong LIU	C104	2024-08-29 15:45	2024-08-29 16:00	2359
Speciation of carbon in silicate melts at high pressure up to 8 GPa	Eun Jeong KIM	C104	2024-08-29 16:00	2024-08-29 16:15	2365
Bonding transitions in amorphous oxides at multi-Mbar: Insights into the structure of oxide melts in Earth's and super-Earth's Interiors	Yong-Hyun Kim	C104	2024-08-29 16:15	2024-08-29 16:30	2362
The possible role of gold-rich colloids in the formation of high-grade supergene gold ores	Yafei WU	C104	2024-08-29 16:30	2024-08-29 16:45	2366
Variations of atomic structures and mechanical properties of natural opal-CT-based geopolymers with synthesis conditions	Hyo-Im KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2368
Structure of silica glasses under ultrahigh pressure: ab-initio calculations of nuclear magnetic resonance properties	Jae-Hyeon PARQ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2369
MAGMATOMIX: a highly efficient post-processing tool for analyzing molecular dynamics simulations	Razvan CARACAS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2370
Evolution of Li environment in partially molten magmas during fractional crystallization: A view from solid-state NMR spectroscopy	Seoyoung LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2371
Comparative study on phase transition of zeolite in subducting slabs by hydrous and anhydrous environments	HYUNSEUNG LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2372
Mechanochemical amorphization of clay minerals: Understanding the role of low-crystalline fault gouge in slip behaviour	Hyun Na KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2374

Title	Presenter	Venue	Start	End	Page
The distribution of H2O bubbles in hydrous albite melts at 0.5 GPa with varying temperature and water contents	Yerin Jeon	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2375
S7 Gem materials		Session Chair: Stefanos KARAMPELAS, SPC			
Gem Materials with Unusual Optical Properties	Andy H SHEN	C104	2024-08-30 08:00	2024-08-30 08:15	2391
The study of external morphology and internal zonal structure of spinel law contact twinned natural macle diamond.	Ahmadjan ABDURIYIM	C104	2024-08-30 08:15	2024-08-30 08:30	2388
An "agate"-like mixed-habit diamond from Yuan River, Hunan, south-central China	Xinwei LIU	C104	2024-08-30 08:30	2024-08-30 08:45	2390
Spectroscopic Analysis of Defects in Photochromic Yellow Sapphire	Yunqi Yang	C104	2024-08-30 08:45	2024-08-30 09:00	2381
Detecting epigenetic iron staining in ruby and sapphire by using Raman spectroscope	Wei ZHOU	C104	2024-08-30 09:00	2024-08-30 09:15	2385
Amphibole inclusions in emeralds	Stefanos Karampelas	C104	2024-08-30 09:15	2024-08-30 09:30	2376
Enhanced Provenance Determination of Turquoise through Comparative Analysis of XRF and LA ICP MS Techniques Coupled with Machine Learning	Bahareh SHIRDAM	C104	2024-08-30 09:30	2024-08-30 09:45	2389
Analysis of the chemical composition of red gem garnets in ancient jewellery by Raman and hand-held X-ray fluorescence spectrometry for origin determination	H. Albert Gilg	C104	2024-08-30 09:45	2024-08-30 10:00	2392
Study of Garnets in GrecoRoman Jewellery from the Collections of Archaeological Museum of Thessaloniki.	Stefanos Karampelas	C104	2024-08-30 10:00	2024-08-30 10:15	2383
Four thousand years of gem garnet trade in NW Africa	H. Albert Gilg	C104	2024-08-30 10:15	2024-08-30 10:30	2379
Gemological Characteristics and Heat Treatment of Trapiche-like Sapphires from Changle, Shangdong province, China	Xiaojing LAI	C104	2024-08-30 10:45	2024-08-30 11:00	2380
A Correlation of Clay Minerals Distribution Map with Jasper Impurities Using Satellite Data in Garut, West Java, Indonesia	Kemala WIJAYANTI	C104	2024-08-30 13:45	2024-08-30 14:00	2387
Geochemistry of blue fluorescence from golden amber in response to thermal maturity	Jing YU	C104	2024-08-30 14:00	2024-08-30 14:15	2377
Accessory minerals under rock-fluid interaction conditions and remobilization of rare lithophile elements in felsic magmatic and metamorphic systems	Martin ONDREJKA	C104	2024-08-29 09:30	2024-08-29 09:45	2408
Unraveling the role of impurities and thermal energy in sapphire structural relaxation: Insights from Raman spectroscopic analysis of heat-treated specimens	Seung Kwon LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2394
XRF and Photoluminescence combined as a tool in the determination of the origin of Colombian emeralds	JAVIER GARCIA TOLOZA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2397
A Study of Turquoise Origins Based on Trace Elements and LDA Method: a Case Study of Liangzhu Culture-related Sites in China	YAN JIANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2398
Synthesis of silica spheres with homogeneous size distribution by electrospray-assisted Stöber method for the fabrication of opal photonic crystals	JUNGMIN KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2400
ICE JADE FROM GUATEMALA	Tao CHEN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2402
Investigation of Traps in Electron-irradiated Sapphire: Insights from Thermoluminescence and Fluorescence Spectrum	Yuyang ZHANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2403
Effect of Fe2O3 Core/SiO2 Shell Nanoparticle Pigments Doping Ratio on the Color of Synthetic Precious Fire Opal	Bowen Li	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2404
Anisotropic photoluminescence in ruby and chrysoberyl	Linling DONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2406
Spectroscopic and DFT study of the orientational order of water molecule and its influence on the coloration of beryl	SUNGJAE KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2407
Formation, identification and color grading of Nanhong agate from the Southwestern of China	Chaowen Wang	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2395
S8 General Topics		Session Chair: Scientific Program Committee			
Hyperspectral Imaging: An effective mineral mapping tool for apatite in the Upper Zone, northern limb, Bushveld Complex	Clement NDOU	C104	2024-08-29 09:45	2024-08-29 10:00	2410
Platinum-group minerals, an experimental overview	Anna VYMAZALOVA	C104	2024-08-29 10:00	2024-08-29 10:15	2412
Natural Radioactivity of the Mesozoic Granites in the Southern Part of the Korean Peninsula	Chaewon KIM	C104	2024-08-29 10:15	2024-08-29 10:30	2413
Reaction Between Feldspar and Water Under the Mantle Transition Zone Conditions	Yeonhak JUNG	C104	2024-08-29 10:30	2024-08-29 10:45	2414
A high-precision measurement method for analyzing Sr, Nd and Sm isotope ratios in single-grain minerals	Guiqin WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2415
ASSESSMENT OF GOLD PROSPECTS AT EXPLORATION OBJECTS IN UZBEKISTAN	Vladimir TSOY	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2416
APOCARBONATE TYPE OF GOLD MINERALIZATION IN UZBEKISTAN, CONDITIONS OF FORMATION AND PREVALENCE	Bobir ISLAMOV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2418
Crystal Structure of Canfieldite	Guanghua Liu	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2420
Minerals in Thin Section (MINTS) – An open-access interactive website for transmitted-light petrographic microscopy	Juergen REINHARDT	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2421

Title	Presenter	Venue	Start	End	Page
Semi-quantitative analysis of minerals in manganese nodule from the Magellan seamount cluster in Western Pacific Ocean	Jeongmin KONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2423
Relationship between distributions of the extra-framework species and adsorption capacity for CO2 gas on synthetic mordenite.	Soojin LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2424
Infrared behavior of phlogopite from some magnesian skarns in the Banatitic Magmatic and Metallogenetic Belt from Romania	Cristina SAVA GHINET	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2425
Structure vs. FTIR and Raman behavior of spodumene from Conţu (Lotru Mountains, South Carpathians, Romania)	Stefan MARINCEA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2427
TOURMALINE AS AN INDICATOR MINERAL FOR BASE METAL AND ASSOCIATED MINERALIZATION IN SUPRACRUSTAL ROCKS OF NORTH SINGHBHUM MOBILE BELT	MANSI JAIN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2429
Structure vs. FT-IR and Raman behavior of wollastonite-2M ("parawollastonite") from Cerboaia Valley, Măgureaua Vaţei (Metaliferi Massif, Apuseni Mountains, Romania)	Delia DUMITRAS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2431
Mineralogical variations of shallow manganese nodules in the East Siberian Sea with respect to water depth	Hyo-Jin KOO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2433
Occurrence of Perovskite-magnetite hosted REE mineralization in Jashora Ultramafic Alkaline Complex, West Karbi Hills, Assam, India.	TAPAN PATOWARY	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2435
Mineral chemistry and trace element variations in index minerals around pyrophyllite deposit in the Mailar village, Lalitpur district, Uttar Pradesh.	MADHUMITA BANERJEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2436
A Comparison Study of Quantitative analysis and Morphology of Microlites in the Obsidians Using Electron Probe Micro Analysis	JIN MI-EUN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2437
Mineralogical studies of iron ore deposits of Sonhari member of Eocene age, Laki Formation, Sindh, Pakistan	Muhammad Hassan AGHEEM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2438
The component analysis and U-Pb dating of cassiterite using LA-(MC)ICP-MS	YounJoong JEONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2440
Production of Montmorillonite Nanosheets using high-energy ball milling: A Study on Milling Methods and Solvent Effects	Bo Gyeong PARK	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2441
T14 Low Temperature Geochemistry					
S1 Challenges and Opportunities of Global-Scale Geochemical Mapping (4th Arthur Darnley Symposium)		Session Chair: Anna LADENBERGER, Maria João Batista			
[Keynote] International Union of Geological Sciences Manual of Standard Methods for Establishing the Global Geochemical Reference Network	ALECOS DEMETRIADES	M316	2024-08-27 14:30	2024-08-27 15:00	2444
The Geochemical Mapping of Ireland: Geological Survey Ireland's Tellus Programme - results, challenges, and outcomes.	Ray Scanlon	M316	2024-08-27 15:00	2024-08-27 15:15	2448
Geochemical Map of Latin America and the Caribbean. Methods for implementation	Maria João Farinha Batista	M316	2024-08-27 15:15	2024-08-27 15:30	2449
Determination of Rare Earth Element Baselines in the Brunei Darussalam Soils.	Haezan JANGARUN	M316	2024-08-27 15:30	2024-08-27 15:45	2464
Soil geochemical mapping of the Aotearoa New Zealand convergent margin	Mark Rattenbury	M316	2024-08-27 15:45	2024-08-27 16:00	2450
Geochemical Mapping in Sweden – establishing baselines at national to local scales	Anna LADENBERGER	M316	2024-08-27 16:00	2024-08-27 16:15	2456
Why stop at the regolith? Plants as an active geochemical mapping sampling media	David Cohen	M316	2024-08-27 16:15	2024-08-27 16:30	2446
Challenges and Opportunities in Compiling a Complete Africa Geochemical Database for Medical Geology Applications	Theophilus Clavell DAVIES	M316	2024-08-27 16:30	2024-08-27 16:45	2465
A COMPREHENSIVE REVIEW OF ABANDONED MINING WASTE FACILITIES TO ASSESS THE REPRESENTATIVENESS OF THEIR SAMPLING	Paula ADANEZ-SANJUAN	M316	2024-08-27 16:45	2024-08-27 17:00	2460
Spatial Distribution of Copper, Iron and Arsenic in soil from the Okahandja 2116 map area in Otjozondjupa Region, Namibia	Badumisa Vicious SIBOLILE	M316	2024-08-27 17:00	2024-08-27 17:15	2454
PLANAGEO-Methodology to conduct a geochemical survey for mineral exploration in SW Angola	Maria João Farinha Batista	M316	2024-08-27 17:15	2024-08-27 17:30	2458
Addressing the problem of microplastic contamination in soil: Challenges during separation and recovery of natural and anthropogenic organic polymers.	Ariadne ARGYRAKI	M316	2024-08-27 17:30	2024-08-27 17:45	2452
Cadmium content in soils of the Upper Silesia Region – an analysis based on geochemical mapping in Poland	Irena Agnieszka WYSOCKA	M316	2024-08-27 17:45	2024-08-27 18:00	2462
State of the art of global geochemical mapping in Mozambique	Vicente Albino MANJATE	M316	2024-08-27 18:00	2024-08-27 18:15	2443
Overview of geochemical mapping in the Geological Surveys of Ibero-America.	Iván MARTÍN-MÉNDEZ	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2467
Nonlinear nature-based localization criteria for the resource potential assessment and interpretation of the anomalous structural-geochemical fields	Igor SPIRIDONOV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2470
THE RESOURCE POTENTIAL ASSESSMENT OF SOLID MINERALS BASED ON THE RESULTS OF MULTI-PURPOSE GEOCHEMICAL MAPPING OF THE TERRITORY OF RUSSIA	Viktor KILIPKO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2471

Title	Presenter	Venue	Start	End	Page
Continental-scale distribution of niobium and tantalum in catchment sediments throughout China: Prospecting implications from the China geochemical Baselines project	Hanliang Liu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2472
USE OF NATIONAL SCALE GEOCHEMICAL DATA FOR THE DEVELOPMENT OF A GEOSTATISTICAL METHODOLOGY FOR INTERACTION ANALYSIS OF VARIABLES AT DIFFERENT SCALES	Paula ADANEZ-SANJUAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2468
S2 Application of metal isotope fractionation in low temperature geochemistry		Session Chair: Kideok KWON, Wei Li			
K isotope separation based on liquid solution centrifugation and its application to cation exchange experiments between birnessite and aqueous solution	Jiayang CHEN	M316	2024-08-26 16:00	2024-08-26 16:15	2474
Comprehensive assessment of Cu, Mo, Pb, and Zn isotopes in contaminated groundwater, surface water, and soil in Erdenet city, Mongolia	Dukmin KIM	M316	2024-08-26 16:15	2024-08-26 16:30	2475
The Cenozoic Seawater Conundrum: New constraints from Mg isotopes	Zhongya HU	M316	2024-08-26 16:30	2024-08-26 16:45	2477
Experimental determination of kinetic isotope fractionation during chemical diffusion of alkaline and alkaline-earth elements in aqueous solution	Weiqiang LI	M316	2024-08-26 16:45	2024-08-26 17:00	2479
Stable chromium isotope fractionation during the alteration of abyssal peridotite: Implications for marine chromium isotope mass balance	LiJuan Li Xu	M316	2024-08-26 17:00	2024-08-26 17:15	2480
Applying standard addition to measure antimony isotopes in low-Sb samples using HG-MC-ICP-MS	Jian-Ming ZHU	M316	2024-08-26 17:15	2024-08-26 17:30	2481
Lithium rich salt lakes in small-scale basin on the Qinghai Tibet Plateau——Tracing by lithium isotope	Maoyong HE	M316	2024-08-26 17:30	2024-08-26 17:45	2482
Links between the Archean anoxic continental weathering and the Great Oxidation Event	KE SHAN	M316	2024-08-26 17:45	2024-08-26 18:00	2483
Tracing meltwater discharge with Ba isotopes from West Greenland fjords	Ruifang C. XIE	M316	2024-08-26 18:00	2024-08-26 18:15	2484
Cadmium Isotope Fractionation during Adsorption onto Edge Sites and Vacancies in Layered Manganese Dioxides	Hui YIN	M316	2024-08-26 18:15	2024-08-26 18:30	2485
Coupling of Molybdenum, Barium, and Sulfur (Mo-Ba-S) biogeochemistry in demarcating past methane seepage episodes	aninda mazumdar	M316	2024-08-26 18:30	2024-08-26 18:45	2486
Equilibrium metal isotopic fractionations at the calcite-water interface	SANGBO SON	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2487
Zinc isotope fractionation during wastewater treatments	Jeonghun KIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2488
Influence of estuaries on chromium isotope ratio and geochemical behavior: A study in two rivers, Kochi, Japan	Akane ITO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2489
S3 Geochemical Signatures of Earth Surface Processes		Session Chair: Scientific Program Committee			
Anthropogenic Activities Have Accelerated the Global Sulphur Cycle	Haoyang NIE	M316	2024-08-27 09:30	2024-08-27 09:45	2493
Heavy metal migration and Lithium isotope fractionation under extreme weathering of basalt on tropical Hainan Island, China	Weihua WU	M316	2024-08-27 09:45	2024-08-27 10:00	2494
Regional Geochemical Survey of the Rooikraaldam Area, Eastern Bushveld Complex, South Africa.	Mehdi BENSID	M316	2024-08-27 10:00	2024-08-27 10:15	2495
Isotopic Behavior and Distribution of Bromine and Chlorine in Evaporites: Insights from the Salina Formation in the Michigan Basin	Yon-Gyung RYUH	M316	2024-08-27 10:15	2024-08-27 10:30	2497
Geochemistry of shale, quartzite and carbonaceous shale of the Cumbum Formation of Kadapa Basin: Implications for provenance, weathering and tectonic setting	Raghunath MISHRA	M316	2024-08-27 10:30	2024-08-27 10:45	2491
Geochemistry, mineralogy, and origin of Late Cretaceous ironstone deposits, Northern Oman Mountains	Salah Al-Khirbash	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2498
Geochemical preservation of Mid-Ordovician carbonates in the Taebaeksan Basin: Insights from strontium isotope analysis	Joonseok LIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2500
Simultaneous measurement of 147Sm/144Nd and 143Nd/144Nd ratios in natural geological samples by MC-ICP-MS after one stage chemical purification using TODGA resin	Yueheng YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2501
Submarine groundwater discharge in coastal zones of a mountainous island: the evidence of trace elements and uranium isotopes	Ruo-Mei WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2502
S4+S5 New geochemical application of Rare Earth Elements and their Isotopes in low temperature geochemical environment		Session Chair: Scientific Program Committee			
Data recovery of incomplete rare earth element data sets	David ERNST	M316	2024-08-27 08:00	2024-08-27 08:15	2503
Formation of H2 by serpentinization of (ultra)mafic rocks	Sookyung KIM	M316	2024-08-27 08:15	2024-08-27 08:30	2505
The Biogeochemical Cycle of Rhenium in the Yangtze River Basin and Perturbations by Human Activities	Yang CHEN	M316	2024-08-27 08:30	2024-08-27 08:45	2506
Geochemical significance of Eu Isotope Ratio in Carbonate rocks	Seung-gu LEE	M316	2024-08-27 08:45	2024-08-27 09:00	2507
CONTRIBUTION TO THE GEOCHEMICAL ATLAS OF THE KINGDOM OF SAUDI ARABIA: GEOCHEMICAL SURVEY OF THE MAHD ADH DHAHAB QUADRANGLE, 23E	Fawwaz AL-FIDANI	M316	2024-08-27 09:00	2024-08-27 09:15	2509
Geochemical features of intrusion related gold deposits (IRGD) in the Yana-Kolyma Gold Belt (Northeast Asia)	Anna Igorevna NESMEYANOVA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2511
Assessing fluoride occurrence in groundwater and related factors in the Eumseong Basin area	Jong Hyun OH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2512

Title	Presenter	Venue	Start	End	Page
T15 Paleoclimate and Paleoceanography					
S1+S2 Paleoclimate and paleoceanography in the Ross Sea, Antarctica		Session Chair: Kyu-Cheul YOO, Sunghan KIM			
Glaciovolcanic processes between the Campbell Glacier and Mt. Melbourne Volcano, Antarctica: Ice and Fire	Hyun Hee RHEE	M315	2024-08-29 08:00	2024-08-29 08:15	2514
Diatom- to coccolithophore-dominant surface production shift during the MPT in the Ross Sea and its implication	Sunghan KIM	M315	2024-08-29 08:45	2024-08-29 09:00	2517
Extent of the marine-based ice sheet in the western Ross Sea during the Last Glacial Maximum	Jae Il LEE	M315	2024-08-29 08:15	2024-08-29 08:30	2515
Sensitivity of the West Antarctic Ice Sheet to +2°C (SWAIS 2C)	Jae Il LEE	M315	2024-08-29 08:30	2024-08-29 08:45	2516
Dinoflagellate cyst assemblages in surface sediments from the Ross Sea, Antarctica	So-Young KIM	M315	2024-08-29 09:00	2024-08-29 09:15	2518
Ice loss from the East Antarctic Ice Sheet in the Ross Sea during late Pleistocene interglacials	Min Kyung LEE	M315	2024-08-29 09:15	2024-08-29 09:30	2519
Enhanced terrestrial methane cycle during the early Eocene hyperthermals	Zuoling CHEN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2520
Lithium isotope evidence for enhanced weathering during the Middle Ordovician	Jena JEONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2521
Depositional records by the active glacier in the northern Drygalski Basin in the Ross Sea since the Last Glacial Maximum	Sangbeom HA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2522
S3 Recent developments in paleoclimatology		Session Chair: Jae-Il LEE			
Minor and trace elemental ratios in coral Porites lobata from Koshiki Island (Japan): evaluation of the temperature proxies	Claire Rollion-Bard	M315	2024-08-29 14:30	2024-08-29 14:45	2523
Biologically mediated trace element mobilization and isotope fractionation: Are certain redox-sensitive trace elements bio-proxies rather than redox-proxies?	Dennis Kraemer	M315	2024-08-29 14:45	2024-08-29 15:00	2525
Giant discoveries for magnetofossils from Cretaceous and Quaternary marine sediments	Courtney WAGNER	M315	2024-08-29 15:00	2024-08-29 15:15	2527
Geochemical evidence for an increased primary productivity during the Bö lling-Alleröd interstadial period compared to Holocene along the south-western continental margin of India	Busnur Rachotappa Manjunaha	M315	2024-08-29 15:15	2024-08-29 15:30	2528
A new method for quantifying astronomical forcing in paleoclimate proxies by evaluating spectral power distribution	Cheng PENG	M315	2024-08-29 15:30	2024-08-29 15:45	2529
Evolution of sea surface temperature in the North Pacific over the past 10 million years	Kyung Eun Lee	M315	2024-08-29 15:45	2024-08-29 16:00	2531
MULTIPLE MIOCENE TROPICAL STORMS RECORDS IN THE EQUATORIAL CARBONATE PLATFORM OF BRAZIL	Orangel AGUILERA SOCORRO	M315	2024-08-29 16:00	2024-08-29 16:15	2534
Land Snail Shell Morphology Records Multiple Orbital Cycles of the Asian Monsoon	RUI Bao	M315	2024-08-29 16:15	2024-08-29 16:30	2530
The effect of barrier layer's evolution in the western Pacific warm pool on the deglaciation	Shuai ZHANG	M315	2024-08-29 16:30	2024-08-29 16:45	2532
Characteristics of late Pleistocene TEX86-based temperatures in the northern Okinawa Trough	Tae Wook KO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2535
Short-term anomalous sea surface temperature events controls growth rates in giant clamshells (Tridacna maxima) of the Lakshadweep Archipelago, India	Fousiya AOUGE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2536
Cretaceous alkenones from Southern high latitudes: potential for paleoceanographic proixies	Takashi HASEGAWA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2537
Seawater temperatures, pH and water mass provenance reconstructions over the last century from cold-water coral geochemistry in the North Atlantic Ocean	Manuel RIGO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2538
Quantitative constraints on the environmental conditions of bauxite formation since Mesozoic	Xiujuan BAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2540
S4 General Topics		Session Chair: Scientific Program Committee			
Pliocene palaeoceanographic changes reconstructed by biomarker analysis of sediments from the Gulf of Alaska of the northeastern North Pacific	Kotaro HOSHI	M315	2024-08-29 09:30	2024-08-29 09:45	2541
Sediments of the Baker-Martinez fjord system (48°S) in Patagonia, Chile, reveal land-ocean interactions over the past 500 years	Javier Eduardo MALDONADO	M315	2024-08-29 09:45	2024-08-29 10:00	2543
Millennial scale variability of Indian Winter Monsoon during mid-late Holocene and its links to Solar Changes: New Evidence from Coastal sediments from Sri Lanka	Hewa Marambage Kusala Madhushani Madhushani PREMARATNE	M315	2024-08-29 10:00	2024-08-29 10:15	2547
Reconstructing Temperature Changes in the Upper Ocean of the Central South China Sea Since the Industrial Revolution Using Cold-water Corals	Xinru HUI	M315	2024-08-29 10:15	2024-08-29 10:30	2548
Late Cretaceous high-resolution sea and lake-level reconstructions based on sedimentary noise modeling: water circulation and orbital forcing	Kaixuan JI	M315	2024-08-29 10:30	2024-08-29 10:45	2550

Title	Presenter	Venue	Start	End	Page
Morphological Variations On The Growth Of Quaternary Saturnalids Radiolaria In The Antarctic Ocean	Girish Kumar SHARMA	M315	2024-08-29 11:00	2024-08-29 11:15	2546
Radiolarian Events and Palaeoceanography of Core ABP-06, Station-I (Section 6), Central Indian Ocean.	ABHISHEK KOHLI	M315	2024-08-29 10:45	2024-08-29 11:00	2545
Catastrophic Flooding during Late Holocene in Northern Bihar Plains, India: A Geo-archaeological Perspective	SHANKER SHARMA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2551
Spatial and Temporal Distribution of Typhoons during the Joseon Dynasty (1392 – 1910)	Jin Gu KANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2552
Terrestrial n-alkane and alkenones flux and its relationship with climate and paleoceanogrphy of the low-latitude Indian Ocean during the Quaternary	Sangmin HYUN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2553
The Strontium and Neodymium isotopic signatures of the Zambezi River Basin in Southern Africa: From source to sink.	Sonwabile Kidwel RASMENI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2554
Calcareous Nannofossil and Paleoclimatic Evolution Across the Eocene Oligocene Transition at IODP Site U1509, Tasman Sea, Southwest Pacific Ocean	Claudia AGNINI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2555
Paleoceanographic changes in the Western Equatorial Pacific Ocean since the latest Miocene: Insights from Planktic Foraminiferal Census Data	Ayushi RAM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2557
The evolution of Southern Benguela Upwelling System and its impact on southwest African climate during the Late Miocene	RUDRA NARAYAN MOHANTY	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2558
Grain size distribution in the Northwest Pacific deep-sea sediments: implication for rare earth elements and Yttrium enrichment	EUIJONG LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2559
T16 Coastal, Marine and Lacustrine Geosciences					
S1 Geohazard assessment from submarine landslides: a multi-stage approach		Session Chair: Seong-Pil KIM, Qiliang Sun			
[Keynote] Geohazard assessment from submarine landslides: a multi-stage approach for the Ulleung Basin	Roger Urgeles	M313	2024-08-26 16:00	2024-08-26 16:30	2561
Generation and propagation characteristics of submarine-landslide tsunami	Ao Sen	M313	2024-08-26 16:30	2024-08-26 16:45	2563
Factors controlling carbonate slope failures: Insight from stratigraphic forward modelling	Jianliang LIU	M313	2024-08-26 16:45	2024-08-26 17:00	2564
Analysing submarine landslide distribution along the Calabrian continental margins, insights from high-resolution morpho-bathymetric data.	Marco BIANCHIN	M313	2024-08-26 17:15	2024-08-26 17:30	2565
Numerical Assessment of tsunamigenesis from submarine mass movements along the slopes of Ionian Calabrian Margin (South Italy)	Xiujuan Wang	M313	2024-08-26 17:30	2024-08-26 17:45	2568
Multistage submarine landslides and their effects on widespread seeps, shallow gas and gas hydrate occurrences	Xiujuan WANG	M313	2024-08-26 17:45	2024-08-26 18:00	2567
Causes of Mass Transport Complexes (MTCs): Implications for the Guyana Basin	Deron Saul	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2570
S3+S2 Coastal Environment Risk and its Influence on the Economic Development of a Country		Session Chair: Ashvin WICKRAMASOORIYA			
Ground subsidence studies of Mumbai city, India using InSAR	Santhosh Kumar SAKTHIVEL	M313	2024-08-27 14:30	2024-08-27 14:45	2571
Tapping into Potential: Unveiling Geological Dynamics and Geohazard Risks in the Potiguar Basin, Brazil	Yasmym Consthance SILVA	M313	2024-08-27 14:45	2024-08-27 15:00	2572
Investigating the influences of an ecological restoration project to the coastal groundwater system along the South Flank of the Yangtze Delta	Bradley Allen A. WEYMER	M313	2024-08-27 15:00	2024-08-27 15:15	2574
Analysis of major Shoreline changes along southern Karnataka coast,India for Five Decades.	Gayathri Nivedha Nivedha R	M313	2024-08-27 15:15	2024-08-27 15:30	2575
Monitoring time-series surface deformation of coastal port area in Busan with space-based radar interferometry	Seongcheon PARK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2577
Earth observation on Asian Mega-deltas environment risk under climate changes and mitigation strategy for sustainable development	Ping YIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2579
Construction of hydrogeological database of coastal reclaimed land considering underground development in industrial area	Juhee KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2580
S4 Beach sedimentary processes and mechanism		Session Chair: Jun-Yong Park, Joo Bong JEONG			
Lithofacies, Petrographic, SEM-EDX, and Isotope Analyses of Emergent Late Holocene Beachrocks as Sea-Level Indicators along the Negros Trench Forearc, Philippines	Lyndon Jr Nawanao	M313	2024-08-27 10:15	2024-08-27 10:30	2583
Geochemical and mineralogical characteristics of beach sediments along the Bay of Bengal coast, Bangladesh	H. M. HOSSAIN	M313	2024-08-27 10:30	2024-08-27 10:45	2581
Investigation of coastal dynamics in the Nakdong Estuary using sediment core biogeochemistry	YUNJI KIM	M313	2024-08-27 10:45	2024-08-27 11:00	2582
Characteristics of surface topography and sedimentation before and after typhoons Kompasu and Soulik in the Gochang Donghori intertidal flat, Korea	Woo Hun RYANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2585
Analysis of seabed stability spatial distribution for underwater platforms	Joo Bong JEONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2586
Spatio-temporal distribution and migration patterns of microplastics on tourist beaches: A case study in the Beidaihe District, North China	Yutao ZUO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2588

Title	Presenter	Venue	Start	End	Page
The Neogene delta-front wave-built sand bodies and their petrophysical characteristics in the Enping Sag of the Pearl River Mouth Basin.	YA XUE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2589
S5 Records of climate and environmental change from lacustrine sediment		Session Chair: Ara CHO, Min HAN			
Variations in paleovegetation and paleoclimate recorded by plant terpenoids in the sediments from Lake Suwa (central Japan) from the last glacial period to Holocene	Ryosuke FUKUCHI	M313	2024-08-27 08:00	2024-08-27 08:15	2592
Hydroclimatic Variability during the 4.2 ka Event: Insights from a High-Resolution Diatom Record in Korea	Ara CHO	M313	2024-08-27 08:15	2024-08-27 08:30	2596
Historical hydroclimate events recorded in paleo-Gaho lake sediments over the past 7ka	Sujeong PARK	M313	2024-08-27 08:30	2024-08-27 08:45	2600
High-resolution paleolake records of late Holocene hydroclimate change in central South Korea and its controlling factors	Arum JUNG	M313	2024-08-27 08:45	2024-08-27 09:00	2599
Paleolimnological analysis of three shallow freshwater lakes in urban development areas around the city of Glasgow, Scotland, UK	Xinchang WANG	M313	2024-08-27 09:00	2024-08-27 09:15	2590
Paleo-oceanographic reconstruction using geochemical and mineralogical proxies from sediment core off Lakshadweep Islands, Arabian Sea	SAINABA N N.K	M313	2024-08-27 09:15	2024-08-27 09:30	2594
Lake-floor signatures revealed by a post-earthquake follow-up geophysical survey	Seong-Pil . Kim	M313	2024-08-27 09:30	2024-08-27 09:45	2597
Late Holocene hydroclimate changes in Tsushima Island, Japan	Jaesoo LIM	M313	2024-08-27 09:45	2024-08-27 10:00	2598
Sedimentary diatom records and climate and environment changes of Yazihai Lake, Ningwu County, Shanxi Province before and after the 4.2 ka event	Huiyuan JIA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2601
Geological and climatic conditions during the Miocene evolution of the North Patagonian Andes, South America: Insights from ancient lake deposits of the Ñirihuau Basin, Argentina	Camila SANTONJA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2602
Mechanism of Salinization in Lacustrine Basins and Organic Matter Enrichment Patterns in Paleolake Water with Different Salinities—A Case Study of the Bohai Bay Basin	Zhenguo QI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2604
Isotopic composition (δ13C, δ15N) and Elemental (C/N ratios) of sedimentary organic matter from a high-altitude mountain lake, western Himalaya: Implications to lacustrine productivity	Aasif Mohmad LONE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2606
Study on atmospheric CO2 concentration and climate change since the Holocene recorded in lake sediments on the Tibetan Plateau	Xueyun MA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2607
Reconstructing Holocene Indian Summer Monsoon Variability Using Multi-proxy Records from Eastern Indian Lake Sediments	ARPITA PARHI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2609
Paleoclimate and Paleoenvironments of Chegarman Lake according to sedimentological and geochemical studies during Late Holocene in SW Iran	Javad DARVISHI KHATOONI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2610
S6+S8 Sedimentation, sediment transport, and morphodynamics on the coastal system		Session Chair: Kyungsik CHOI, Ho Kyung Ha			
Monitoring of the land-sea interface: Analysis of high-resolution time series from 1950 to the present-day illustrating erosion, transport, and coastal sedimentation processes on the west Atlantic coast of France.	David MENIER	M313	2024-08-27 16:00	2024-08-27 16:15	2612
Human-controlled discharge effect on hydrodynamic and benthic sedimentary processes in the tide-dominant estuary	Seong Woon JEONG	M313	2024-08-27 16:15	2024-08-27 16:30	2614
Seasonal controls on the channel morphodynamics in an open coast macrotidal flat, west coast of Korea	Seolhui BANG	M313	2024-08-27 16:30	2024-08-27 16:45	2615
Variations in flocs related to wind-induced turbulent shear in macrotidal flat, Asan Bay	Sun Min CHOI	M313	2024-08-27 16:45	2024-08-27 17:00	2616
Tidal and seasonal influences on the morphodynamic evolution of the tidal channels in a macrotidal embayment: Garolim Bay, west coast of Korea	Seungyeon SOHN	M313	2024-08-27 17:00	2024-08-27 17:15	2617
Chronology of raised marine terraces at the coasts of Tamil Nadu, South India- Implications on palaeotsunmi and higher sea-level	LINTO ALAPPAT	M313	2024-08-27 17:15	2024-08-27 17:30	2618
Distribution Characteristics and Accumulation Mechanism of High Saturation Gas Hydrates in the Makran Accretionary Prism offshore Pakistan	JING LIAO	M313	2024-08-27 17:30	2024-08-27 17:45	2619
Analysis of characteristics of seaweed forest distribution area using acoustic exploration method (multi-beam echo sounder)	SoonYoung CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2620
Sediment Dynamics in the Nakdong River Estuary, South Korea: Insights from the Nakdong Estuary Information Service System (NEISS)	Jun-Ho Lee	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2621
Deciphering Dokdo Seamount's Submarine Topography: Generation and preservation of submarine terrace structure	Duhwan KEUM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2622
Multiscale Sea-Level Variability and Predictive Modeling in the Northern South China Sea Under Climate Change	Yilin YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2623
Characteristics of surface sedimentary facies in the Watan Estuary intertidal flat, western Korea	Woo Hun RYANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2624
Coastal Topography Monitoring utilizing CubeSat Constellation, in Hujeong Beach, South Korea	byunggil LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2625
Exploring spatiotemporal variations in sediment retention in delta evolution: A numerical experiment with Delft3D	Minsik KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2626

Title	Presenter	Venue	Start	End	Page
Investigating and quantifying tidal effects on the formation of bifurcated channel networks in modern river deltas	Jiyoung LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2627
Effect of coastal seiches on sediment transport in a Masan Bay	JUN YOUNG SEO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2628
Impact of dike construction on sedimentary facies and morphological evolution of semienclosed macrotidal flats in the western coast of Korea	Joohee JO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2629
Volatile geochemistry of inorganic gases emitted from the Central Indian Ridge 9°44' - 15°33'S using H_2, He, CO_2, and CH_4	Heejun KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2631
Evolution of the Eastern Gulf of Finland area through Holocene	Olga KOVALEVA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2632
Pockmark Seafloor in Hupo Basin, East Sea	Chang Hwan KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2633
Progress on Geoscientific Map Series of China-ASEAN Seas and Adjacent Areas	Baojun WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2634
Influence of meteorological events on the sediment and microphytobenthos resuspension in intertidal flats	Hun Jun HA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2635
Exploring Novel Bioactive Compounds from Deep-Sea Microorganisms Originating in Marine Sediments	Ji Young LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2636
Analysis of benthic environment characteristics and microbial community structure in Suyeong River, South Korea	Hee Eun WOO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2637
Harmonizing marine geological data to support the sustainable use of the maritime areas and their resources - EMODnet Geology as an example	Anu Marii KASKELA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2655
S7 EMODNET-Geology's new standards revealing Earth's seabed geology		Session Chair: Anu Kaskela, Xavier Monteys			
EMODnet-Geology's new standards revealing Earth's seabed geology	Henry T. V. VALLIUS	M317	2024-08-28 08:00	2024-08-28 08:15	2650
Mapping the sedimentation rates in the continental shelf – an European view to the seabed change	Aarno Tapio Kotilainen	M317	2024-08-28 08:15	2024-08-28 08:30	2638
Cross-EEZ Cooperation, Standards and Harmonization: Compiling Spatial Data of the European Seafloor Geology and Geomorphology within the EMODnet Geology Project	Kristine E.C. ASCH	M317	2024-08-28 08:30	2024-08-28 08:45	2640
Advancing the Understanding of Seabed Substrate Characteristics: Insights from EMODnet Geology	Susanna KIHLMAN	M317	2024-08-28 08:45	2024-08-28 09:00	2642
Brazilian research in the Atlantic Ocean	Luciana Felicio PEREIRA	M317	2024-08-28 09:00	2024-08-28 09:15	2644
Hadal Trenches: highly variable geological environments on the Earth	Hiroshi KITAZATO	M317	2024-08-28 09:15	2024-08-28 09:30	2652
Collating and harmonizing data on geological events in European seas	Andrea FIORENTINO	M317	2024-08-28 09:30	2024-08-28 09:45	2645
Paleobotanical zoning of exposed continental shelves as a tool to overcame geographical discontinuity of scattered paleolandscape data	Francesco Latino CHIOCCI	M317	2024-08-28 09:45	2024-08-28 10:00	2647
Europe's marine minerals: EMODnet geology	Xavier MONTEYS	M317	2024-08-28 10:00	2024-08-28 10:15	2649
Need for the uniform information in multinational marine areas - Experiences from the harmonization within seabed substrate data	Susanna KIHLMAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2653
MAPPING THE MARINE GEOLOGICAL RESOURCES OF THE CARIBBEAN SEA IN THE EMODnet-GEOLOGY PROJECT	Teresa MEDIALDEA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2657
First comprehensive assessment of pockmarks and debut of susceptibility mapping along the Italian Continental Margins	Francesco CHIOCCI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2659
T17 Geoscience in Alpine and Polar Regions					
S1+S4 Status of Himalayan Glaciers under the current climate change scenario		Session Chair: Rasik RAVINDRA, N C Pant			
Ground ice formation mechanisms constrained by stable water isotope ratios and occluded gas compositions	Nikolai FEDOROV	M317	2024-08-26 16:00	2024-08-26 16:15	2661
A comparison of the geochemistry between the Chokurdakh ice wedge and the central Yakutian ice wedges formed during the Last Glacial Maximum (LGM)	Nayeon KO	M317	2024-08-26 16:15	2024-08-26 16:30	2662
Characterization of the electrical response of subglacial bedrock in Antarctica considering free pore water and film water	Yuanyuan ZHANG	M317	2024-08-26 16:30	2024-08-26 16:45	2663
Time-series deformation monitoring of post-glacial rebound using space-based synthetic aperture radar observations	Seong-Woo JUNG	M317	2024-08-26 16:45	2024-08-26 17:00	2665
Understanding Intra/inter-regional Heterogeneous Glacier Retreat and Glacier-Climate Synthesis over the Himalayas	Parvendra KUMAR	M317	2024-08-26 17:00	2024-08-26 17:15	2666
Effect of varying the fluidity parameter in Glen's Law on ice sheet dynamics using 2D finite element software, Elmer/ice.	Su-Jeong LIM	M317	2024-08-26 17:15	2024-08-26 17:30	2667
Exploring the Soft-Sediment Deformation Structures (SSDS) in Glacial Environments: Insights from Physical Dropstone Deposition's Simulations	Ana Beatriz Dias JARDIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2668
Elevation changes of the ice sheet above subglacial lakes around David Glacier in East Antarctica measured using Sentinel-1 DDInSAR	Taewook Kim	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2670
An Innovative Experiment of Geophysical Measurements with Low-Altitude UAV in the Ingrid Christensen Coastal Ice Sheet	Changchun ZOU	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2672
Diel variations in isotopic and chemical compositions of stream water in Antarctica	Hyejung JUNG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2673

Title	Presenter	Venue	Start	End	Page
Development and benchmarking of ice sheet dynamics model using COMSOL Multiphysics® compared to Ice Sheet System Model (ISSM)	Yi-Jeong BAEK	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2674
Meltwater influence on sulfur isotope composition of sulfate in ice wedge	Hyeonjeong JEONG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2675
S2 Arctic evolution and climate changes during the Cenozoic		Session Chair: Jung-Hyun KIM, Jochen Knies			
[Keynote] Arctic Ocean pH and CO2 history of the last glacial cycle	Jannik Martens	M317	2024-08-27 08:00	2024-08-27 08:15	2677
A digital geoscience data repository for Arctic reconstructions	Carmen GAINA	M317	2024-08-27 08:15	2024-08-27 08:30	2679
Impact of current flow on the depositional environment in Kongsfjorden trough of Arctic Svalbard	Youngkyu AHN	M317	2024-08-27 08:30	2024-08-27 08:45	2682
Glacier-induced provenance changes in Bellsund, Svalbard, during the Holocene	Young Jin Joe	M317	2024-08-27 08:45	2024-08-27 09:00	2676
Brackish and anoxic environments in the western Arctic Ocean during the last glacial period: insights from authigenic calcites	kwangchul JANG	M317	2024-08-27 09:00	2024-08-27 09:15	2681
Variations in aged-soil derived organic carbon input into the Kongsfjord over recent centuries: application of CuO oxidation products	Dahae KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2683
Biogeochemical evidence for methane emission within gas hydrate bearing mound structures of the Chukchi borderland in the western Arctic Ocean	Dong-Hun LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2684
Persistent marginal sea ice conditions in the Eurasian Arctic during the past 750 000 years	Jochen Knies	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2685
S3 Ice core science for alpine and polar ice cores		Session Chair: Jin-Ho AHN, Jinhwa SHIN			
Novel insights and paleoclimate impact of the Millennium Eruption from Mt. Baekdu	Giyoon LEE	M317	2024-08-27 09:30	2024-08-27 09:45	2686
Greenhouse gas (CO_2, CH_4) alteration in shallow ice of Larsen blue-ice area, northern Victoria Land, East Antarctica	Giyoon LEE	M317	2024-08-27 09:45	2024-08-27 10:00	2687
Identification of the source of the 1458/58 CE bipolar volcanic event in the Vostok firn core using a novel quantitative approach for analyzing unpolished small (< 10 µm) glass shards	Seokhyun RO	M317	2024-08-27 10:00	2024-08-27 10:15	2688
Assessing Artificial Intelligence Techniques to Simulate Atmospheric CO_2 Concentration from Antarctica Ice Core Records During MIS 1 to 5	Nasrin SALEHNIA	M317	2024-08-27 10:15	2024-08-27 10:30	2690
Dating of a coastal East Antarctic ice core by using high-resolution impurity records and reconstruction of historical snow accumulation variability	Seokhyun RO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2691
Geochemical characterization of East Siberian ice wedges : Implications of their origin and paleoenvironment	Subon KO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2693
T18 Groundwater and Hydrogeology					
S1 Microplastics and nanoplastics in soil and groundwater		Session Chair: Jin-Yong LEE, Wainka Chia Rogers			
[Keynote] Microplastics and nanoplastics in groundwater: the essential role of the hydrogeologists	STEFANO VIAROLI	M311	2024-08-27 08:00	2024-08-27 08:15	2694
A Comprehensive Analysis of How Drought Affects Groundwater Microplastics	WAINKWA CHIA Chia ROGER	M311	2024-08-27 08:15	2024-08-27 08:30	2695
Microplastic pathways into bedrock aquifers: focusing on groundwater well management in Korea	Eunju JEONG	M311	2024-08-27 08:30	2024-08-27 08:45	2696
Global Occurrence, Concentrations, and Characteristics of PFAS in Groundwater: A literature Review	Jihye Cha	M311	2024-08-27 08:45	2024-08-27 09:00	2697
Risk of microplastic contamination in groundwater wells from plastic casings and pipes	Michele LANCIA	M311	2024-08-27 09:00	2024-08-27 09:15	2698
Comparative adsorption characteristics of Pb and Cd by microplastics based on particle size	Taejung Ha	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2699
Soil and groundwater microplastic pathways and related impact on human health	Ntegang Venant Atem	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2700
S2 Groundwater Development for achieving food security and improving rural health in low- income countries		Session Chair: S. D. Limaye, Shreerup Goswami			
Appraisal of groundwater quality for drinking and irrigational purposes from parts of Warora tehsil, Chandrapur district, Maharashtra state, India.	Alka Kumari MISHRA	M311	2024-08-27 09:30	2024-08-27 09:45	2702
Kinetic, Thermodynamics and Equilibrium studies on adsorption of perchlorate ion on SIR-110-HP resin in groundwater.	BHAGIRATHI BEHERA	M311	2024-08-27 09:45	2024-08-27 10:00	2704
Groundwater salinization in the dry zone of Sri Lanka and its impact on food security and livelihood: A case study from the Medderambawa cascade irrigation system	Chirath CHANDRARATHNA	M311	2024-08-27 10:00	2024-08-27 10:15	2707
Seasonal dynamics of groundwater Arsenic pollution: A multivariate statistical approach of One-way ANOVA and Shannon entropy weight	Imran Khan	M311	2024-08-27 10:30	2024-08-27 10:45	2701
Groundwater based drinking water scarcity: a geomorphological approach	Bhagyashri Chandrakant MAGGIRWAR	M311	2024-08-27 10:45	2024-08-27 11:00	2706
Hydrogeochemical Assessment of Groundwater Quality in N'kapa, Littoral Region Cameroon: Implications for Sustainable Domestic, Agro-Industrial, and Irrigation Use	Virgine EBIA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2709

Title	Presenter	Venue	Start	End	Page
Groundwater exploration for the development of agricultural irrigation in Wang Nam Yen District, Sa Kaeo Province	Chunintorn CHAMATHONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2711
Irrigation Groundwater Quality for Agricultural Usuability and food security: A case study of Mahakalpara block of Kendrapada District, Odisha.	SUSHANT SAMAL	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2713
Geospatial Distribution and Health risk assessment of Fluoride in groundwater of Balasore district, odisha, India.	Utsav DAS	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2714
ASSESSMENT OF GROUNDWATER STORAGE ZONES FOR SUSTAINABLE AGRICULTURAL PRACTICES IN MAHARASHTRA STATE, INDIA USING GRACE SATELLITE DATA AND RS-GIS TECHNIQUES	BHAVANA UMRIKAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2715
Remediation Strategies for Elevated Iron Levels in the Lower Reaches of the Mahanadi Delta: A Comprehensive Review	SUHANI SRUJANIKA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2716
Geochemical Processes Affecting Fluoride Mobilization in the hard-rock Aquifers of Central India: Implication for Ensuring fluoride-safe drinking water supply	Naved ALAM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2717
Application of Bio-waste derived adsorbent obtained from Acacia nilotica and Neolamarckia cadamba fruits for Removal of fluoride from drinking water	NARENDRA KUMAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2719
Geological Influences on Water Quality: Implications for Agriculture and Food Security in the Athgarh Basin, Odisha	Shreerup GOSWAMI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2721
S3 Integrated use of groundwater and surface water resources keeping up with extreme droughts periods		Session Chair: Byung-Sun LEE			
Effect of Climatic Conditions on Groundwater Potability in the Hambantota District in Sri Lanka	Ashvin Kamal Wickramasooriya	M311	2024-08-27 14:30	2024-08-27 14:45	2723
Monitoring studies within the Orto-Alish artesian basin (Kyrgyzstan) under climate change conditions.	Dmitrii PLAKSIN	M311	2024-08-27 14:45	2024-08-27 15:00	2724
Groundwater change and sustainable management using monitoring wells in the Kanto Groundwater Basin, Japan	Kunio FURUNO	M311	2024-08-27 15:00	2024-08-27 15:15	2726
Cases of Groundwater Dam Construction in Areas of Poor Water Supply	Hyun PARK	M311	2024-08-27 15:15	2024-08-27 15:30	2728
[Plenary] Impact of Climate Change on Groundwater Resources and Way Forward	Elango LAKSHMANAN	M311	2024-08-27 15:30	2024-08-27 15:45	12
Geospatial Assessment of Drought Vulnerability in Nira River Basin, Western India	PAYAL WAINDESHKAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2729
Long term base flow assessment according to land use and climate change on Yeongsan and Seomjin river basins, South Korea	Kyoochul HA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2730
S4 Eco-hydrological Process and its Effects in Karst Environment		Session Chair: Guanghui JIANG, Xuan Yu			
[Keynote] Hydrological processes in karst critical zones in southwest China	Jun Zhang	M311	2024-08-27 16:00	2024-08-27 16:15	2732
Observation and Characterization of Rapid Infiltration and Runoff Processes in Karst Hillslopes	Jun Zhang	M311	2024-08-27 16:15	2024-08-27 16:30	2731
Geospatial patterns in the hydroecological characteristics of surface waters in the karst area of Samcheok, South Korea	Regina Martha Gabest LUMONGSOD	M311	2024-08-27 16:30	2024-08-27 16:45	2735
Hydro-ecological processes of hyporheic zone and the function degradation in karst spring-fed pools	Fang GUO	M311	2024-08-27 16:45	2024-08-27 17:00	2736
Water age dynamics in transpiration for typical plants under different earth critical zones	Zidong Luo	M311	2024-08-27 17:00	2024-08-27 17:15	2737
Development construction of water resources in karst peak cluster depression based on subsurface and vadose zone hydrological processes	Fan LIU	M311	2024-08-27 17:15	2024-08-27 17:30	2738
Examining the Changes in Karst Spring Flow Over an Extended Gauging Period: Impact of Climate and Vegetation Recovery	Guanghui JIANG	M311	2024-08-27 17:30	2024-08-27 17:45	2740
Coupled physically based hydrologic model and transit time theory (SWAT-SAS) for simulating the eco-hydrological process in karst basins	Wuhua LI	M311	2024-08-27 17:45	2024-08-27 18:00	2734
DETERMINATION OF PETROLEUM PRODUCTS IN WASTEWATER BY GRAVIMETRIC METHOD	MUNISXON MEYLIYEVA	M311	2024-08-27 18:00	2024-08-27 18:15	2741
S5 KRC Special session: Drought vulnerability of groundwater aquifer under climate crisis environment in S. Korea		Session Chair: Gyusang LEE, Hwan-Ho YONG			
Suggestions for Korea's groundwater use and management in the era of climate crisis	Kang Kun LEE	M317	2024-08-28 14:30	2024-08-28 15:00	2745
Case Study on the Operation of Hybrid Artificial Recharge Circulation System in Drought-Prone Areas	Gyoo-Bum KIM	M317	2024-08-28 15:00	2024-08-28 15:30	2746
Enhancement of denitrification using agricultural biproducts and limestone for use in the artificial recharge system	Boyeon JEON	M317	2024-08-28 15:30	2024-08-28 16:00	2748
Assessment of Groundwater Drought Evolution Over Two Decades in Korea Using Storage-Based Approach	Anuradha Karunakalage	M317	2024-08-28 16:00	2024-08-28 16:30	2743
A technical approach on agricultural groundwater irrigation by applying the well-network system (WNS) to a drought-prone zone, South Korea	Byung Sun LEE	M317	2024-08-28 16:30	2024-08-28 17:00	2747
S6 Groundwater and surface water interactions		Session Chair: Steven Berg, Hyoun-Tae Hwang			
[Keynote] Integrated surface and subsurface hydrological modeling to support water management	Rene THERRIEN	M311	2024-08-28 09:30	2024-08-28 09:45	2760

Title	Presenter	Venue	Start	End	Page
Saltwater circulation driven by shoreline curvature in coastal aquifers	Xuan YU	M311	2024-08-28 09:45	2024-08-28 10:00	2749
Exploring heterogeneity in the Varaždin aquifer: Integrating geostatistics and Markov chain analysis with borehole log and electrical resistivity tomography data	Igor Karlovic	M311	2024-08-28 10:00	2024-08-28 10:15	2754
Optimizing DNAPL Source Identification in Varied Real Field Scenarios with Scarce Data Using Linked Simulation-Optimization	Jun-Young SHIN	M311	2024-08-28 10:15	2024-08-28 10:30	2755
Application of feature-based clustering and machine learning to investigate spatiotemporal patterns and controlling factors of the groundwater level of Jeju Island, South Korea	Jimin HWANG	M311	2024-08-28 10:30	2024-08-28 10:45	2756
The susceptibility of urban hard rock aquifer in equatorial climate to hydraulic and contaminant stresses: The case of Shah Alam, Malaysia.	norsyafina roslan	M311	2024-08-28 10:45	2024-08-28 11:00	2759
Hydrochemical Analysis of groundwater in Chamoli district, Garhwal Himalaya India	Abhishek Mehra	M311	2024-08-28 11:00	2024-08-28 11:15	2757
Hydrogeological modelling of alluvial aquifer in north-eastern Uzbekistan	AZIZ HAKIMOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2750
Groundwater of the foothill plain on the northern slopes of the ridge Nuratau and features of their interaction with surface water	Nosirali KURBANOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2752
Assessing changes in hydrogeological conditions during solid minerals development: an in-depth analysis	Gleb ZARNITSYN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2761
A Study into the assessment of groundwater flow utilizing thermal and hydrochemical datasets from both groundwater and surface water in the karst area of Samcheok, South Korea	Han-Sun Ryu	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2763
Using 3D geology models to support and improve decision-making in water resources regulation in England.	Michael Kehinde MBE CGEOL	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2764
Numerical calculation and case analysis of seepage field in anisotropic aquifer	Lei LYU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2766
Study on the quality of water wells in the city of Hashtgerd using hydro-geochemical charts	Zahra SHARIFI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2767
Evaluation of the impact of artificial replacement on groundwater in the Yongding River	Tian NAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2769
Pollutant Migration in mineral area through Copper Isotope Values in Soils and Waters	JINGWEN SU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2770
S7 General Topics		Session Chair: Scientific Program Committee			
Analysis of Oxygen and Hydrogen Isotopes in Groundwater Basin: Mapping of Origins, Dynamics, and Use of Groundwater Resources in Bandung Basin Area	Dewandra Bagus Eka Putra	M311	2024-08-28 14:30	2024-08-28 14:45	2771
Estimation of the CO2 emission flux to the air by groundwater extraction in Korea	Jiwook JANG	M311	2024-08-28 14:45	2024-08-28 15:00	2776
Geological Characterization and Modeling in Southeastern Florida (USA) to Inform the Design of a Coastal Subsurface Monitoring Network	Miguel E. VALENCIA	M311	2024-08-28 15:00	2024-08-28 15:15	2777
A new approach to vulnerability analysis of Asian aquifers: machine learning and geochemical evidence	Wengeng CAO	M311	2024-08-28 15:15	2024-08-28 15:30	2781
Assessing the impact of climate change on hydrological components using CMIP6 GCM models of the Hasdeo river basin, Chhattisgarh, India: Implications for sustainable water resources in the future	satish B	M311	2024-08-28 15:30	2024-08-28 15:45	2772
Deciphering probable groundwater recharge patterns in Khapri watershed of Deccan Volcanic Province (DVP), western India: Insights from stable isotopes	Chinmay Uday DONGARE	M311	2024-08-28 15:45	2024-08-28 16:00	2774
Fluoride in groundwater of a hard rock sub-basin of northern Karnataka, India – sources and controlling geochemical processes	TEJASWAI LAKKUNDI	M311	2024-08-28 16:00	2024-08-28 16:15	2775
An introduction to the National Groundwater Monitoring Network for Systematic Management of Korea's Groundwater Resources	Laesoo KANG	M311	2024-08-28 16:15	2024-08-28 16:30	2778
Prediction of Fluoride Concentrations in Groundwater Using Machine Learning and Human Health Risk Assessment in Eastern India	SUBHASISH TRIPATHY	M311	2024-08-28 16:30	2024-08-28 16:45	2780
Geological Characteristics of Coastal Aquifer in the southwest of Korea	SUNG KEUN LIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2782
Groundwater basin management in Japan with quantitative and qualitative modeling	Katsuhiro FUJISAKI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2783
Contaminant Transport Simulation in Industrial Complex Area	YU-CHUL PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2784
Hydrogeochemistry and mechanism controlling the groundwater chemistry along the Kankai River Basin, East Nepal Himalaya	Champak SILWAL	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2785
Geology-related groundwater productivity analyses based on the specific capacity data in South Korea: Case for the Geumgang and Nakdonggang river basin	Sang-Ho MOON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2787
Relationship between Spatiotemporal Groundwater Quality and Changing Land Use and Land Cover in Korea: A Comprehensive Approach Utilizing Monitoring Data and GIS	Chanhyeok Jeon	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2789
Enhancing Measurement of Groundwater Flux: Synergistic Effects of Polysulfone-Activated Carbon Composite Carriers	Hyemin PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2790

Title	Presenter	Venue	Start	End	Page
Anomalous uranium occurrence in southern Telangana, India and its societal implications: Evidence from geological, geophysical, and hydrogeological studies	RAMESH GUGULOTH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2791
A Study on Groundwater Treatment and Useful Resources Recovery Methods in Uzbekistan	Kyungwon Na	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2793
Changes in soil characteristics due to long-term groundwater artificial recharge	Myoung-Rak CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2795
Development of a predictive model for chloride ion and nitrate nitrogen concentrations in groundwater using ensemble models	Chan-Ik HWANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2796
Modeling seawater intrusion and brine water injection impact in a complex volcanic aquifer of East Jeju, Jeju island, South Korea	Dewandra PUTRA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2797
Recharge processes and chemical evolution of groundwater affected by geogenic and agricultural contamination in the mountainous areas with granitic and sedimentary bedrocks	Hyo-Sik Seo	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2798
Stable water isotopes (δ18O, δD) and groundwater dating tools (3H, CFCs) coupled with hydrochemistry to evaluate groundwater flow dynamics of complex basaltic aquifer	Hyun-Ji Kang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2800
Exploration of Groundwater in the Eastern Region of Thailand for Sustainable Groundwater Management	Benya SUNANTA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2802
Groundwater recharge estimation along a climate gradient - a Northern Namibian case study	Josefina Hamutoko	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2803
Hydrogeochemical Appraisal and macrophyte diversity in Inland water bodies of a subtropical country	DEEPTI PANDEY	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2804
Occurrence and behavior of nitrate and per- and polyfluoroalkyl substances (PFAS) in groundwater of Haean basin, Korea	seunghoon CHOO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2805
Criteria of groundwater level change in relation to the operation of a river barrage	Se-Yeong HAMM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2806
Analysis of freshwater-saltwater interface in the aquifer around Hwajinpo lagoon on the Eastern Coast of Korea: Potential implications for coastal ecosystem	Minji KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2807
Delineation of Seawater intrusion in the coastal aquifer using the 3-Dimensional Groundwater modelling in the Harbour city of Thoothukudi, Tamil Nadu, India.	THIRUMURUGAN MARIMUTHU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2808
Geochemistry of Accessory Minerals as Sources of Radionuclides in Mesozoic Granite Aquifers of Korea	Jin-Yong LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2809
Comparison of occurrence characteristics of PFAS in Korean groundwater and surface water using online SPE-LC-MS/MS	Sang Hun AN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2810
Identification of arsenic spatial distribution by hydrogeochemical processes represented by different ion ratios in the Hohhot Basin, China	Yu REN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2812
Groundwater and Environmental Challenges in Asia	Yanpei CHENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	2813
T19 Geobiology					
S1 Microbial carbonates through space and time		Session Chair: Joydip Mukhopadhyay, Jeong-Hyun LEE			
[Keynote] Oxygenation and marine microbial carbonates: The long history	Robert RIDING	M214	2024-08-29 08:00	2024-08-29 08:15	2827
Nubecularia-coralline algal-serpulid-microbial bioherms of the Paratethys Sea – distribution and paleoecological significance (upper Serravallian, upper Sarmatian, Middle Miocene)	Werner E. E. Piller	M214	2024-08-29 08:15	2024-08-29 08:30	2814
The basal Triassic microbialites, between reef building and red ammonoid limestone	Aymon BAUD	M214	2024-08-29 08:30	2024-08-29 08:45	2816
Carbonate platform configuration and microbial sedimentation in the Mesoproterozoic Penganga Platform, Peninsular India	Joydip MUKHOPADHYAY	M214	2024-08-29 08:45	2024-08-29 09:00	2818
Trophic level variability of an intertrappean lake during Deccan volcanism: New insights using stable isotopes	Yogaraj BANERJEE	M214	2024-08-29 09:00	2024-08-29 09:15	2820
Biochemical Ba cycling in microbial mats through deep time: Insights from Ba concentrations and isotopes in stromatolitic carbonates	Simon V. Hohl	M214	2024-08-29 09:15	2024-08-29 09:30	2822
Carbonate mineral precipitation induced by microorganisms enriched from the cave water and biofilm in Yongcheon Cave, Jeju Island	Yul ROH	M214	2024-08-29 09:30	2024-08-29 09:45	2824
Abiotic and biotic constraints on Earth's ancient colonisers	Indrani MUKHERJEE	M214	2024-08-29 09:45	2024-08-29 10:00	2826
Microstructural Analysis of Recent and Pleistocene Stromatolites at Ruidera Pools, Spain.	Mar SIMONET RODA	M214	2024-08-29 10:00	2024-08-29 10:15	2829
Dissolved silicon as a beneficial factor for biomineralization of protodolomite by a halophilic cyanobacterium	Ting CHEN	M214	2024-08-29 10:15	2024-08-29 10:30	2830
Diverse origins and depositional environments of phytoclast tufas from the Cretaceous Jinju Formation, Korea	Seunghoon LEE	M214	2024-08-29 10:30	2024-08-29 10:45	2831
S2 Assessing the interplay of environmental and evolutionary controls in animal-substrate interactions through time		Session Chair: Anthony Shillito, Romain Gougeon			

Title	Presenter	Venue	Start	End	Page
[Keynote]Infaunal feedback during the end-Permian Mass Extinction: Evidence from ichnology	Mao LUO	M214	2024-08-29 15:30	2024-08-29 15:45	2837
Ichnological record of palaeonvironmental changes and its cyclostratigraphic aspects in the Sinemurian-Toarcian basinal deposits from the Mochras drill core, Cardigan Bay Basin, UK	Alfred Uchman	M214	2024-08-29 15:45	2024-08-29 16:00	2832
Early colonization of the deep-sea bottom–the protracted build-up of an ecosystem	Luis A. BUATOIS	M214	2024-08-29 15:00	2024-08-29 15:15	2834
Temporal constraints on the ichnofacies paradigm	Anthony Shillito	M214	2024-08-29 15:15	2024-08-29 15:30	2838
The interplay of evolutionary, taphonomic, and environmental controls on trace fossils from Burgess Shale-type deposits	Gabriela Gabriela MANGANO	M214	2024-08-29 14:30	2024-08-29 15:00	2839
Evolution and palaeoenvironmental migration of a Cambrian undermat-miner	Li-Jun ZHANG	M214	2024-08-29 14:45	2024-08-29 15:00	2841
The use of time-environment matrices to decipher behavioural events in early Paleozoic animal evolution	Romain GOUGEON	M214	2024-08-29 16:00	2024-08-29 16:15	2835
Integrated sedimentological and ichnological analysis of Holocene deposits in the Nakdong River delta, South Korea	BOHYUN JEON	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2842
Lipid Biomarker Patterns Reflect Nutritional Strategies of Seep-Dwelling Bivalves From the South China Sea	Hongxiang GUAN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	2843
S3 Mid-Phanerozoic mass extinctions, recovery, extreme environmental events and integrated stratigraphic correlations		Session Chair: Yu Pei			
[Keynote] Mid-Phanerozoic major environmental perturbations and ecosystem responses	Zhong-Qiang CHEN	M214	2024-08-30 08:00	2024-08-30 08:15	2859
The Guadalupian Extinction: Severity, Selectivity, and Timing	Matthew CLAPHAM	M214	2024-08-30 08:15	2024-08-30 08:30	2863
Early Permian carbonate buildups from eastern Inner Mongolia, North China: Insights regarding the late Early Permian Turnover	Zhen YAN	M214	2024-08-30 08:30	2024-08-30 08:45	2856
Organic matter influence on ooid formation: New insights into classic examples (Great Salt Lake, USA; Triassic Germanic Basin, Germany)	Yu PEI	M214	2024-08-30 08:45	2024-08-30 09:00	2850
Dynamic variations of carbon-sulfur cycles through the Late Permian to Early Triassic	Lei ZHANG	M214	2024-08-30 09:00	2024-08-30 09:15	2866
Millennial-scale variations of Carbon-Sulfur isotopes were regulated by microbe activities following the end-Permian extinction	zijie zheng	M214	2024-08-30 09:15	2024-08-30 09:30	2854
A new charophyte flora from early Middle Triassic (Guizhou, South China) indicates ecologic adaptation to shallow marine	Meijia Zhang	M214	2024-08-30 09:30	2024-08-30 09:45	2858
Upper Triassic (middle Norian) conodont biostratigraphy succession from eastern Tibet, southwest China	Zhengyi LYU	M214	2024-08-30 10:00	2024-08-30 10:15	2861
Secular variations of ichnofossils before and during the Carnian Pluvial Episode from the continental Upper Triassic successions, South China	Liao YANG	M214	2024-08-30 10:15	2024-08-30 10:30	2864
New Hybodont sharks (Chondrichthyes, Elasmobranchii) from the Early Triassic continental Dongchuan Formation (Yunnan Province, China), revealing the recovery of lacustrine ecosystems after the end-Permian mass extinction	Wen WEN	M214	2024-08-30 10:30	2024-08-30 10:45	2845
Marine carbonate factory changes across the end-Permian mass extinction in South China	Danna LIU	M214	2024-08-30 10:45	2024-08-30 11:00	2848
The earliest record of freshwater siliceous algae from the Middle Triassic: Chrysophyte stomatocyst from the Ordos Basin, North China	Bohang CHENG	M214	2024-08-30 13:45	2024-08-30 14:00	2851
Silicified gastropod fossils from the uppermost Permian of Guangxi Province, South China	Jie Liu	M214	2024-08-30 14:00	2024-08-30 14:15	2853
Microbial bloom, microbe-metazoan interaction and palaeoecologic crisis linked with volatile volcanisms during the Guadalupian-Lopingian (Permian) transition	Zhensheng Wei	M214	2024-08-30 14:15	2024-08-30 14:30	2846
Middle Jurassic restructuring of palaeo-food webs stabilized dinosaur-dominated communities in Southwest China	Yuangeng HUANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2867
S4 General Topics		Session Chair: Scientific Program Committee			
Organic geochemical evidence for episodic elevated precipitation in the Carnian Pluvial Episode	HUIWEN LI	M214	2024-08-30 14:30	2024-08-30 14:45	2868
Tracing Dissolved Oxygen Variability in Riverine Environments: A High-Resolution Study Using *Lamprotula leai* Shell Trace Elements	Xinran Su	M214	2024-08-30 14:45	2024-08-30 15:00	2869
Rise of calcareous deposition during the Carnian Pluvial Episode (Late Triassic)	QILE qile GENG	M214	2024-08-30 15:00	2024-08-30 15:15	2871
The habitat of the Ediacaran Period fossil Dickinsonia: Redox conditions of the fossiliferous Cherny Kamen Formation in the Ural Mountains	Natasha BYKOVA	M214	2024-08-30 15:15	2024-08-30 15:30	2872
Vanadate reduction by gram-positive fermentative bacteria isolated from deep-sea sediments on the northern Central Indian Ridge	Bokyung KIM	M214	2024-08-30 15:30	2024-08-30 15:45	2874
Arsenic immobilization using combined treatment of arsenite-oxidizing bacterium and biochar	So-Jeong KIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	2875
T20 Biogeochemical cycles					

Title	Presenter	Venue	Start	End	Page
S3+S2 Local scale fluxes of carbon dioxide in urban environment: Sectorial emission and sequestration challenges		Session Chair: Scientific Program Committee			
Greenhouse gas molar ratios and stable isotopic compositions in Seoul Mega City	JeongEun KIM	M317	2024-08-27 16:00	2024-08-27 16:15	2876
Optimizing Carbon Sequestration in Winter Wheat in Wooster, OH	Grace BRAVER	M317	2024-08-27 16:15	2024-08-27 16:30	2881
Rock Weathering Dynamics in Himalaya: Insights from Metagenomics and U-series Isotopes	Pradeep Srivastava	M317	2024-08-27 16:30	2024-08-27 16:45	2882
Inventorization of Green House Gases – Sources and Sinks in Urban Delhi, India	CHIRASHREE GHOSH	M317	2024-08-27 16:45	2024-08-27 17:00	2879
Unravelling Carbon Fluxes in Delhi's Urban Fabric: Emission and Sequestration Dynamics	SHAILENDER KUMAR	M317	2024-08-27 17:00	2024-08-27 17:15	2877
Analysis of the impact of crushed basalt dust addition to corn fields on the diversity and functionality of soil microbiota	Hao-Cheng Chang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2883
S4+S1 General Topics		Session Chair: Scientific Program Committee			
Secondary mineralization of Sb(V)-bearing Fe(III) phases stimulated by Fe(II) under advective flow and the impact on Sb mobility	Yidan ZHANG	M317	2024-08-27 14:30	2024-08-27 14:45	2884
Microbial communities development and secondary minerals formation during microbial Fe(III) reduction across a pH gradient	Yunseo Jang	M317	2024-08-27 14:45	2024-08-27 15:00	2885
Internal P-recycling in Late Ordovician marine reefs: the first evidence from the mutualistic commensalism of cyanobacteria and green algae in the fossil record	Jinwen SHEN	M317	2024-08-27 15:15	2024-08-27 15:30	2887
The relationships between vertical variations of shallow gas and pore water geochemical characteristics in boreholes from the inner shelf of the East China Sea	xue LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2889
Investigate the impact of different fertilizers in combination with dicyandiamide on bacterial communities participating in nitrogen and methane cycles	Hao-Yu CHU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2890
Isotopic distribution of bioavailable Sr, Nd, and Pb in Chungcheongbuk-do Province, Korea	Min-Ji JUNG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2891
T21 Environmental Geosciences					
S1 Geoscience knowledge in Environment and Environmental Ecosystem		Session Chair: Shahina TARIQ			
Potential of Geoscience knowledge towards Environmental Ecosystem	Shahina TARIQ	M215	2024-08-26 16:00	2024-08-26 16:15	2894
Ground Substrate: Conceptual Proposal, Scientific Connotation and Great Significance	Zhiqiang YIN	M215	2024-08-26 16:15	2024-08-26 16:30	2895
Earth System Modeling for Explaining and Predicting changes in the Climate, Water, and Ecosystem	June-Yi LEE	M215	2024-08-26 16:30	2024-08-26 16:45	2897
DISTRIBUTION OF HEAVY METALS IN SOILS AND PLANTS IN MINING WASTE STORAGE AREAS UZBEKISTAN	Nosir SHUKUROV	M215	2024-08-26 16:45	2024-08-26 17:00	2900
Providing the most appropriate management solution based on the new conditions of Urmia Lake, Northwest of Iran	Razyeh Lak	M215	2024-08-26 17:00	2024-08-26 17:15	2893
Studying on the structural features of municipal solid waste landfills before recultivation	Elena SOLOMATINA	M215	2024-08-26 17:15	2024-08-26 17:30	2898
Redox activity of soil dissolved organic matter as affected by soil warming	Shuhan WANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2901
Assessment of Seawater Intrusion Signatures: A Geochemical and Geospatial Study in the Coastal Region of Paradeep Municipality, Jagatsinghpur, Odisha.	SUSANTA KUMAR DAS	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2902
Understanding Loggerhead Sea Turtle Nesting Preferences in Broward County, Florida	Brooke Marlo WALKER	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2903
Geochemical Characteristics of Coal Mine Drainage and Waste Rocks from Livingstonia Coalfield in Malawi	Amidu Amali MAKWINJA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2904
S3+S2 Anthropogenic contaminants in the environment		Session Chair: Scientific Program Committee			
Estimation of heavy metal(loid) accumulation rate in urban soil using in situ pXRF: the example of Shijiazhuang City, China	ZHAOXIAN YUAN	M215	2024-08-27 08:00	2024-08-27 08:15	2906
Seasonal variations of microplastics in a coastal wetland from southwest India and their risks to *Gerres filamentosus* and *Sillago sihama*	Anish Kumar WARRIER	M215	2024-08-27 08:15	2024-08-27 08:30	2907
Impact of subsurface material on the quality of groundwater in the vicinity of the Gohagoda waste disposal site in Kandy, Sri Lanka	Ashvin Kamal Wickramasooriya	M215	2024-08-27 08:30	2024-08-27 08:45	2908
Meltwater - contamination indicator of industrial areas (Baikal region, Russia)	Evgeniia TSVETKOVA	M215	2024-08-27 08:45	2024-08-27 09:00	2909
A SPATIO-TEMPORAL RECORD OF MICROPLASTICS DURING THE PAST FOUR DECADES IN A LACUSTRINE SEDIMENTARY SEQUENCE FROM SOUTHERN INDIA	Sandeep KIZHUR	M215	2024-08-27 09:00	2024-08-27 09:15	2911
DEVELOPMENT OF METHODS FOR PHYTOREMEDIATION OF CONTAMINATED SOILS USING TOLERANT PLANTS OF LOCAL NATURAL LANDSCAPES (UZBEKISTAN)	Nosir SHUKUROV	M215	2024-08-27 09:15	2024-08-27 09:30	2912
Lead (Pb) Contamination and Associated Health Risks in the Mining Town of Rosh Pinah, Namibia.	Michelle Uetupa Hailonga	M215	2024-08-27 09:30	2024-08-27 09:45	2914

Title	Presenter	Venue	Start	End	Page
Microtechnofossils as a multiproxy record for the human-impacted sediments	Zdzisław M. Migaszewski	M215	2024-08-27 09:45	2024-08-27 10:00	2917
On the proper use of geochemical indices in pollution assessment of the road dust	Agnieszka GALUSZKA	M215	2024-08-27 10:00	2024-08-27 10:15	2919
Associated Professor	Jia Duo	M215	2024-08-27 10:15	2024-08-27 10:30	2922
Overcoming Construction Management Challenges During the Remediation of a Former Gold/Arsenic Mine in Ontario, Canada	MARK William PRIDDLE	M215	2024-08-27 10:30	2024-08-27 10:45	2916
METAL ACCUMULATION COMBRETUM IMBERBE, CYNODON DACTYLON AND SPOROBOLUS AFRICANUS AT KLEIN LETABA TAILINGS STORAGE FACILITY, LIMPOPO PROVINCE, SOUTH AFRICA	Phumudzo Gift MUNYAI	M215	2024-08-27 10:45	2024-08-27 11:00	2920
Why is the air humid during wintertime heavy haze days in Beijing?	Jiarui WU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2923
Impacts of changes in land use and land cover between 2001 and 2018 on summertime O3 formation in North China Plain and surrounding areas-A case study	jiaoyang YU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2924
Hydrochemical characterization and indicators of anthropic influence on groundwater surrounding Guanabara Bay, Rio de Janeiro, Brazil	Alexis Rosa NUMMER	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2925
Study of soil contamination in vicinity of the municipal solid waste landfills after recultivation	Irina VASILEVNA Galitskaya	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2926
Characterization and adsorption properties of rectorite/sludge derived biochar composites for Pb(II) removal	huanhuan WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2928
Seasonal Changes in the Eutrophication Index and Alleviation of Eutrophication with Calcium-Citrate Complex in the Surface Water of Osongji (Osong Pond), Jeonju-si, Korea	Suyeong Noh	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2929
Pore-scale simulation of CO2-water-rock Interaction on Rock Permeability and Mechanical Properties	Yang BO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2931
Tree stumps as passive sampler for trace metal dust deposition	Shubin ZHOU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2933
Assessment of Ground Water Quality by Statistical Methods in Greater Bangalore, South India	Hemamalini Rajanna R	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2934
Mercury in soils near a base metal smelting plant, Plovdiv, Bulgaria	Lora BIDZHOVA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2936
SOIL POLLUTION ASSESSMENT IN ALMALYK MINING AREA USING PRINCIPAL COMPONENT AND CLUSTERING ANALYSIS	Nosir SHUKUROV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2938
A review of heavy metal contamination around Rosh Pinah area in Southern Namibia	Michael Action EINO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2940
Effect of salinity on arsenic mobilization from desulfurized and filtered mine tailings	Rocky KUBUYA KIRO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2942
Tracing Sources of Zinc Contamination in Groundwater of Industrial Complexes Using Zinc and Sulfur-Oxygen (S-O) Isotopes	Dae-Gyu IM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2943
Eco-friendly natural mineral biotite as a cesium adsorbent: Utilizing low-concentration acid and hydrogen peroxide	Sunki KWON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2945
FEATURES OF ANOMALIES OF POLARIZABILITY AND RESISTANCE OF THE INDUCED POLARIZATION METHOD IN THE LIGHT OF PREDICTING GROUNDWATER POLLUTION BY PETROLEUM PRODUCTS	Qodirjon MINGBOYEV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2946
Tracing iron mining dam collapse pollutants from the Fundão-Mariana accident (2015), using Nd-Sr isotopes in sediments from the Doce River and adjacent marine environment	Claudio de Morisson VALERIANO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2948
S4+S5 Emerging environmental pollutants, hazards, and energy resources and their associated human-natural system risks: Oral and postal presentation		Session Chair: Stefano Viaroli, Wainkwa Chia Rogers			
Examples of the advection mechanism of contaminated groundwater due to VOCs to deep aquifers and the advection of contaminated groundwater in aquifers with different flow directions: wells that diffuse contaminated groundwater deep and wells that do not	Osamu KAZAOKA	M215	2024-08-27 14:30	2024-08-27 14:45	2949
Identification of *As-III* and *As-V* species in As-contaminated water using cupric acetate monohydrate	Swati GANVEER	M215	2024-08-27 14:45	2024-08-27 15:00	2931
Characterization of urban aquifers of an Asian megacity (Shenzhen, China) using chemical, antibiotics, and isotope analyses	STEFANO VIAROLI	M215	2024-08-27 15:00	2024-08-27 15:15	2955
Urban local body - Farmer partnership for sustainable waste management and organic farming	Kiran D A	M215	2024-08-27 15:15	2024-08-27 15:30	2953
Pb isotopic source tracing and mass balance on heavy metals from East Kolkata Wetland, a Ramsar site of West Bengal, India	KAMALAKANNAN D	M215	2024-08-27 15:30	2024-08-27 15:45	2932
Exploring Management Practices of Tailings and their Impact on the Downstream Economies and Environment; insights from Uis, Namibia.	Hilya Ndeyapo AMUKWA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2957
The Lower Paleozoic strata in the Baltic Syneclise (NE Poland) – reconstruction of paleoenvironmental conditions based on the distribution of biomarkers	Pawel KOSAKOWSKI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2958
Dr	Qian Jiang	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2960
Estimative engineering geological zoning for the disposal of municipal solid waste	Olga Nikolaevna EREMINA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2961

Title	Presenter	Venue	Start	End	Page
Spatial Analysis and Probabilistic Risk Assessment of Heavy Metal Contamination in Urban Soils: A Case Study from Seoul, South Korea	Hyunsoo Seo	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2963
Assessment of Current Water Quality Status of Rivers near Two Major Cities in Myanmar	Arkar SAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2965
CO2 measurement with high spatiotemporal resolution using low-cost sensors in urban Seoul, South Korea	JaeYoung PARK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2966
Regional features of ecological-geological systems of rock massifs in Kamchatka	Violetta SHANINA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2967
Spatiotemporal characterization of iron and manganese distribution in a stratified aquifer during in-situ chemical oxidation operation	Seoyoung SON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2969
Assessment of heavy metal pollution in marine sediments around southern waters of Gyeonggi Bay	Hyerim LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2970
Tracking tobacco-specific nitrosamines (TSNAs) source in fertilizer: an environmental forensic approach	Min-Hui Son	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2971
The relationship between the intensified heat waves and deteriorated summertime ozone pollution in the Beijing–Tianjin–Hebei region, China, during 2013–2017	Ruonan WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2972
Environmental pollution problems in the mining regions	Elena Nikolaevna LEVCHENKO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2973
Arsenic contamination in ground water, mechanism and role of subsurface sediments for high arsenic concentration, in the Flood Plain of Ghaghara River, Uttar Pradesh. India	Abhinandan SRIVASTAV	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2974
Composition and size distribution of wintertime inorganic aerosols at ground and alpine regions of northwest China	Haijiao Liu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2976
Occurrence and behavior of per- and polyfluoroalkyl substances (PFAS) and antibiotics in the hyporheic zone	Hyobin LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2977
EFFECTS OF ACID MINE DRAINAGE FROM COAL MINING ON WATER QUALITY IN THE ARARANGUÁ RIVER BASIN	Marlon Colombo HOELZEL	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2978
Dust generated by e-waste processing: Impact of sample treatment and decomposition method on chemical and isotopic compositions	Eva Martinková	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2979
State-of-the-art integration of digester, heating system and automation	Atta ur RAHMAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2981
Contribution of Geogenic Radon for Indoor Air Quality using Grey-Box Modeling	Yijune CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2982
Development of Vapor Intrusion Risk Assessment Program for Urban Subsurface Environments	Min Seo BAE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2983
New insights from landfill microbiome by genome-resolved metagenomics	So-Jeong KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	2984
T22 GIS and Remote Sensing					
S1+S11 Remote Sensing of Global Resources with the New and Forthcoming Generation of Satellite Sensors		Session Chair: Carlos Roberto de Souza FILLHO			
[Keynote] CURRENT AND FUTURE HIGH-RESOLUTION THERMAL INFRARED-SATELLITE AND AIRBORNE- SENSOR SYSTEMS	Simon John HOOK	C109	2024-08-26 16:00	2024-08-26 16:15	2987
50 years of Lithologic Mapping and Mineral Exploration from Space	Michael ABRAMS	C109	2024-08-26 16:15	2024-08-26 16:30	2985
Characterization of "Sale 'e Porcu" salty pond (SPp Sardinia, Italy) suitable for CAL/VAL activities using multi sensor approach in the VNIR-TIR range: new optical satellite mission perspective	Maria Fabrizia BUONGIORNO	C109	2024-08-26 16:30	2024-08-26 16:45	2991
The EnMAP hyperspectral satellite: an overview of the mission and its applications in geology and resource exploration	Saeid Asadzadeh	C109	2024-08-26 16:45	2024-08-26 17:00	2990
A Multiscale Hyperspectral Remote Sensing Approach for Detection of Petroleum Offshore	Carlos Roberto Souza Filho	C109	2024-08-26 17:00	2024-08-26 17:15	2989
Remote Measurement of the Earth system with EMIT Imaging Spectroscopy from the International Space Station	Robert Otis Green	C109	2024-08-26 17:15	2024-08-26 17:30	2995
Assessing Spatio-temporal Changes of climate variables on Diverse Crops in region of Punjab, Pakistan	Waqar YASIN	C109	2024-08-26 17:30	2024-08-26 17:45	2996
Active deformation across Indo-Myanmar suture zone, NE India: Insights from integrated RS-GIS-based Geomorphic Investigations	ALEXANDER S KSHETRIMAYUM	C109	2024-08-26 17:45	2024-08-26 18:00	2993
Detection of high-geothermal-potential zones in densely vegetated areas through a combination of vegetation and mineral indices derived from hyperspectral satellite imagery	Taiki KUBO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2997
DELINEATION OF MINERAL POTENTIAL HYDROTHERMAL ALTERATION ZONES AND FAULT ZONES USING MULTISPECTRAL ASTER AND LANDSAT 8 DATA OVER SANDUR SCHIST BELT, BELLARY DISTRICT, KARNATAKA, INDIA.	VIJAYAKUMAR MOOLA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	2999
Research on Vegetation Geochemical Anomalies in Uranium Mining Areas Based on Hyperspectral Remote Sensing and Vegetation Spectral Analysis	Yongfei CHE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3001
S2 Geoscience information, geological mapping and modelling		Session Chair: Kristine ASCH			
[Keynote] Bathy-morphological mapping for geohazard assessment	Francesco Latino CHIOCCI	C109	2024-08-27 08:00	2024-08-27 08:30	3010
Thematic mapping, potential and interactions	Roland Erich OBERHAENSLI	C109	2024-08-27 08:30	2024-08-27 08:45	3014

Title	Presenter	Venue	Start	End	Page
Boosting Europe's Energy Transition: The Pivotal Contribution of a Geological Service for Europe in Delivering FAIR Subsurface Data and Knowledge for Informed Policy and Industrial Decision-Making	Patrick Wall	C109	2024-08-27 08:45	2024-08-27 09:00	3006
Towards an integrated and harmonized geological data model for Europe	Esther HINTERSBERGER	C109	2024-08-27 09:00	2024-08-27 09:15	3015
Polish Geological Cartography Platform: fostering geological map data accessibility, enhancing integration and harmonisation for informed decision making	Katarzyna JÓŹWIK	C109	2024-08-27 09:15	2024-08-27 09:30	3003
Geological Map of South America in the twenty–first century	Jorge GÓMEZ TAPIAS	C109	2024-08-27 09:45	2024-08-27 10:00	3017
A structural map of Italian seas, thematic map derived from collation and harmonization of geological data	Andrea FIORENTINO	C109	2024-08-27 10:00	2024-08-27 10:15	3012
Computing Sediment Grain Volumes with GIS	Tim Whiteaker	C109	2024-08-27 10:15	2024-08-27 10:30	3002
Spatial relationships between gold deposits, crustal structures, and geophysical fields using GIS and statistical analysis in Central Kyzylkumes, Uzbekistan	Bakhtier NURTAEV	C109	2024-08-27 10:30	2024-08-27 10:45	3019
Lime phosphates in Senegal: characterization, modelling and predictive mapping for the development of a prospecting guide.	Abdoul Aziz NDIAYE	C109	2024-08-27 10:45	2024-08-27 11:00	3004
On the issue of developing a methodology for compiling a map for assessing the anisotropy of the natural stress state of dispersed soil massifs	Violetta SHANINA	C109	2024-08-27 11:00	2024-08-27 11:15	3008
Exploratory modeling of Giran Rig- Chah Sangi area (Sistan and Baluchestan Province, Iran)	Elnaz Aghaali	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3021
The geochronological database of Colombia: Review and new geological perspectives for this sector of the Americas	Daniela MATEUS ZABALA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3022
New edition of the Geological Map of Colombia at a scale of 1:1,5M	Vanessa Rey León	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3024
Surface and subsurface geological data in Italy: state of the art of the harmonization process.	Marco PANTALONI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3026
Exploration and Application of High-Precision Inclined Photography and 3D Modeling Technology in Digital Geological Outcrops	Zongqi Lin	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3028
Geological and Prospectivity mapping of phosphates deposits in the Senegalese sedimentary basin	Mamadou Fall	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3030
Innovative Approaches to 3D Geo-Modeling of Geological Structures: Integration of Laser Scanning and Digital Photogrammetry, case studies from Ukraine	Mariia OLIINYK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3032
Detecting Brittle Structures in Vegetated Landscapes with Sentinel-2 Data: A Case Study of Deep Geological Repository Site Assessment	Jan JELENEK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3034
(Open)GeoSGB: State of the art of Transition to an Open Source, semi-automated, FAIR-ready Geological Spatial Data Infrastructure of the Geological Survey of Brazil	CARLOS EDUARDO MOTA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3035
Rapid Geological Modelling for Surat Basin Based on Well Logs	GUOXU CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3037
GEODEATLAS.nl; A web-based GIS resource atlas showing multiple geo-energy uses to support subsurface planning	Susanne NELSKAMP	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3038
S5+S3+S6 Advances in GIS and remote sensing approach for geological hazards management		Session Chair: Scientific Program Committee			
The Landslide Whisperer: An Intelligent and Efficient Framework for wrapped Interferogram Detection of Potential Hazards	Ruixuan Zhang	C109	2024-08-28 08:00	2024-08-28 08:15	3040
Multi-frequency SAR time-series analysis of ground subsidence at coastal reclaimed land in Busan	Jeong-Heon JU	C109	2024-08-28 08:15	2024-08-28 08:30	3044
Coastal Change from Space: Geohazard Assessment using S1-SAR and S2 datasets	Xavier MONTEYS	C109	2024-08-28 08:30	2024-08-28 08:45	3045
Multitemporal Monitoring of Landslides using Remotely Piloted Aircraft (RPA) and Structure from Motion–Multi View Stereo (SfM-MVS): Case Studies in Brazil	Camila Duelis VIANA	C109	2024-08-28 08:45	2024-08-28 09:00	3047
Utilizing PSInSAR and Open-Source Software for Monitoring Slow-Moving Landslides: A Case Study from Southern Taiwan	Abhishek Ravindra LAKHOTE	C109	2024-08-28 09:00	2024-08-28 09:15	3049
Fostering New Talent: Exploring Innovative Approaches in Geoscience to Meet 21st Century Societal Needs	Courtney Elaine Jermyn	C109	2024-08-28 09:15	2024-08-28 09:30	3050
The f(utility) of GIS-based landslide susceptibility: a review approach	Mihai Niculiță	C109	2024-08-28 09:45	2024-08-28 10:00	3041
Geospatial Analysis of Coastal Dynamics and Development Strategies: A Case Study of Nagapattinam District, Tamil Nadu, India	Isai RAMACHANDRAN	C109	2024-08-28 10:00	2024-08-28 10:15	3046
InSAR analysis for monitoring Cultural Heritage threatened by multiple risk and anthropogenic hazards: the seaport quarter in Valparaiso (Chile) case study.	Daniele SPIZZICHINO	C109	2024-08-28 10:15	2024-08-28 10:30	3042
Landslide susceptibility assessment using Mahalanobis Distance-based class imbalance strategies: A comparison of under-sampling, over-sampling, and hybrid sampling techniques	Kounghoon NAM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3051
Opportunities of Advanced Remote Sensing for Rock Mass Classification on Inaccessible High Alpine Rock Slopes	Nicole OYSMUELLER	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3052

Title	Presenter	Venue	Start	End	Page
A Study on the Utilization of GNSS Data for Monitoring the Stability of the Yangsan Fault	Heeun KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3053
Geological Risk Mapping in the Largest City in Brazil: From Paper Reports to Artificial Intelligence	Thais Feitosa TREVISANI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3054
2023 Multi-temporal Surface Deformation and Activity Evaluation of Deep-Seated Landslide Sites	Suet-Yee AU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3056
Remote Sensing Technology Applied to the Potential Analysis of Engineering Geological Disasters	Tsung ting CHEN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3057
Assessing Landslide Vulnerability in Sindhudurg District, Western India: Integrating Stakeholder Perspectives and Geospatial Analysis	AMIT VIJAYKUMAR SHIRKE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3059
Research on Precipitation Prediction and Geological Disaster Warning Based on Infrared Remote Sensing and Deep Learning	jingyi zhang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3060
Geological Hazard Mitigation Portal of Indonesia	Ahmad BARNES	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3061
Integration of ISAR and GNSS for Monitoring the Stability of Artificial Slope: a Case Study of Lijiang, China	Yinjie CAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3062
Multi-Sensor Remote Sensing Data and Deep Learning for Time-Series Analysis of Caldera Lake Dynamics at Mt. Changbai: Monitoring Volcanic Activity	EURU LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3064
Assessing the Potential of Novel Remote Sensing Techniques in Landslide Monitoring and Susceptibility Mapping	Dylan GORDON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3066
Mitigating decorrelation noises and atmospheric delays in InSAR	Jun HU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3067
High-Density and High-Temporal-Frequency Monitoring of Reservoir Landslides with InSAR based on Environmental Prior Information	Qian SUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3069
S7 Mapping the Way Forward: Advances in Applied Geoinformatics for Mineral Exploration		Session Chair: Mana RAHIMI			
[Keynote] Assessment of Machine Learning Techniques for Prospectivity Modeling and Vectoring of IOCG Mineralizations	Carlos Roberto Souza Filho	C109	2024-08-27 16:00	2024-08-27 16:30	3079
Identification of lithium deposits information based on two Chinese satellites	Nannan ZHANG	C109	2024-08-27 16:30	2024-08-27 16:45	3071
Exploration Information System (EIS): Open-Source Toolkit & QGIS Plugin for Mineral System Modelling and Mineral Predictive Mapping	Vesa Nykänen	C109	2024-08-27 16:45	2024-08-27 17:00	3072
Characterization of mineral systems in northern Finland using autoencoders- and self-organizing maps-based deep learning architecture.	Bijal Chudasama	C109	2024-08-27 17:00	2024-08-27 17:15	3074
Sparse spectral unmixing applied to hyperspectral satellite imagery for accurate identification and mapping of hydrothermal alteration minerals	Masahide KISHIMOTO	C109	2024-08-27 17:15	2024-08-27 17:30	3075
Spectral Geological mapping in Kuhi area, Maharashtra, with AVIRIS-NG Airborne Hyperspectral Data	Trina Vishal VYAS	C109	2024-08-27 17:30	2024-08-27 17:45	3076
Approaches and Technologies of the Digital Twin of Russia's Mineral Resources: possibility of using the experience of the Karpinsky Institute for the development of information systems in geological surveys and institutes	Olga KOVALEVA	C109	2024-08-27 17:45	2024-08-27 18:00	3077
Enhancing Mineral Prospectivity Mapping for Cu-Pb-Zn in Faraj Abad, Qom, Iran: A Comprehensive Integration of Geology, Geochemistry, and Remote Sensing Data Using Fuzzy Analytical Hierarchy Process Models.	Kamyar KESHAVARZ	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3081
Identification of High-grade Ni Laterite Ores Using Hyperspectral Imaging and Deep Learning	Koichi FURUKAWA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3082
Advancing Mineral Resource Prediction through Distributed Cloud Computing and Remote Sensing: A Case Study in Namibia	Tianyi LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3084
Hydrothermal Alteration Mapping using Remote Sensing and GIS in parts of North Purulia Shear Zone (NPSZ), Purulia District, West Bengal, India	Anirudh CHAKRABORTY	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3085
S8 Advances in AI and remote sensing approach for tidal flat monitoring		Session Chair: Scientific Program Committee			
Evolution of a Sand Spit in Ujeon Tidal Flat at Sinangun, Jeollanamdo, Korea's West Coast	Jun-Ho Lee	C109	2024-08-29 08:00	2024-08-29 08:15	3086
Guided sampling method of diffusion model for cloud area restoration from tidal flat satellite images	Donguk Lee	C109	2024-08-29 08:15	2024-08-29 08:30	3087
Performance comparison of waterline based topographical mapping of tidal flats with different spatial interpolation methods	Jingyo Lee	C109	2024-08-29 08:30	2024-08-29 08:45	3089
Airborne Sensor system for monitoring Tidal Flat	Hyunsoo Hur	C109	2024-08-29 08:45	2024-08-29 09:00	3090
Exposure Duration and Geochemical Influences on Surface Sediment Properties for Monitoring Approach at Hwangdo Tidal Flat, Taean, Cheonsu Bay, Korea's West Coast	Jun-Ho Lee	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3091
S9 Artificial Intelligence Methods Applied to Geological hazard using Remote Sensing and GIS		Session Chair: Scientific Program Committee			
Land Subsidence Observation using InSAR Time-Series Analysis of Bangkok and Samut Prakan, Thailand	Raisa Najma Sakina	C109	2024-08-29 09:30	2024-08-29 09:45	3093
Identification of slope failure by random forest using topographic characteristics changes	Mitsunori UEDA	C109	2024-08-29 09:45	2024-08-29 10:00	3094

Title	Presenter	Venue	Start	End	Page
Integrating InSAR Time-Series Machine Learning Optimized and Susceptibility Assessment for Monitoring Land Subsidence in the Iron Mining Site Musan	Muhammad Fulki Fadhillah	C109	2024-08-29 10:00	2024-08-29 10:15	3096
S10 Geoscience Information in the 2020s		Session Chair: Harvey THORLEIFSON			
New opportunities with Earth Science data platforms in Europe: fostering next-generation cross-domain research and decision-making	Marc URVOIS	C109	2024-08-27 14:30	2024-08-27 14:45	3099
International geoscience terminology management and governance	Mark Rattenbury	C109	2024-08-27 14:45	2024-08-27 15:00	3101
A Framework for Smart Geological Mapping Using Data and Knowledge Hybrid-drivenFAIR	Yongzhi WANG	C109	2024-08-27 15:00	2024-08-27 15:15	3102
Geoscience Information in the 2020s	Harvey Thorleifson	C109	2024-08-27 15:15	2024-08-27 15:30	3104
NSDI Implementation at the Ministry of Mines and Energy in Namibia	FREDDY MUYAMBA	C109	2024-08-27 15:30	2024-08-27 15:45	3097
EarthResourceML 3.0	Michael Graham SEXTON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3105
Building a Digital Framework for Europe's Geology: GSEU and the Significance of Data Modelling and Vocabularies	Kristine ASCH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3106
REASSESSMENT OF DETAILED LITHOLOGICAL MAPPING USING A MACHINE LEARNING ALGORITHM: A CASE STUDY ON THE BOA VISTA SHOSHONITIC STOCK IN NORTHEASTERN BRAZIL	Mariana Izabel Tomaz de LIMA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3108
Serverless Computing Powered Efficient Remote Sensing Image Processing: A Case Study on Potential Sand Source Identification in the Yarlung Zangbo River Middle Reaches	Qing LAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3110
Enhancing Environmental Understanding with Spatio-Temporal Knowledge Activation in Large Language Models	Xinhua FAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3111
T23 Seismology					
S2+S1 Statistical Seismology and Episodic Events		Session Chair: Scientific Program Committee			
Estimation of earthquake hazard parameters of delineated sources of the Shillong Plateau, Northeast India and adjoining regions	MOHD SHAHABUDDIN	M213	2024-08-28 08:00	2024-08-28 08:15	3114
Unraveling Seismic Patterns: A Deep Dive into Earthquake Sequences and Swarms in Northeastern Algeria through a Dual Method Approach	Sofiane Taki-Eddine Rahmani	M213	2024-08-28 08:15	2024-08-28 08:30	3112
Using eathquake time series to characterize seismicity in the Mount Cameroon	Delair ROUAI	M213	2024-08-28 08:30	2024-08-28 08:45	3115
A regional insight on the tectonic and geometric configuration of the Bengal Basin for hosting predicted mega earthquakes	MIR FAZLUL KARIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3116
S3 East Asia Earthquakes, Seismic Structure and Tectonics		Session Chair: Won-Young KIM, YoungHee KIM			
[Keynote] Lithosphere structure from comparative tomographic study: Implications for deformation mechanisms of the Tibetan Plateau	Xiaodong SONG	M213	2024-08-27 08:00	2024-08-27 08:30	3132
HIGH RESOLUTION P AND S WAVE VELOCITY STRUCTURES OF THE EASTERN SINO-KOREAN CRATON	Yanbing LIU	M213	2024-08-27 08:30	2024-08-27 08:45	3118
Do Subducted Seamounts Act as Weak Asperities?	Sungho Lee	M213	2024-08-27 09:00	2024-08-27 09:15	3127
Crustal Structure in the Southeastern Korean Peninsula Using a Receiver Function Analysis	Jeongin Lee	M213	2024-08-27 09:15	2024-08-27 09:30	3128
Constraints on crustal seismic properties of the southern Korean Peninsula using Virtual Deep Seismic Sounding	Young Oh SON	M213	2024-08-27 09:30	2024-08-27 09:45	3123
Recent Earthquakes along the Ogcheon Fold Belt in the Korean Peninsula	Won-Young Kim	M213	2024-08-27 09:45	2024-08-27 10:00	3117
The 2022 Goesan earthquake of the moment magnitude 3.8 along the buried fault in the central Korean Peninsula	Hobin LIM	M213	2024-08-27 10:00	2024-08-27 10:15	3120
Focal Mechanism Solutions and Crustal Stress Field around the Korean Peninsula	Dong geon KIM	M213	2024-08-27 10:15	2024-08-27 10:30	3125
Utilization of Regional Lg Wave in Precise Epicentral Relocation and Source Characterization of Two 2021 Earthquake Sequences in Gunsan Basin, Yellow Sea	JUN YONG PARK	M213	2024-08-27 10:30	2024-08-27 10:45	3130
Fault complexity revealed by focal mechanisms of small earthquakes in Gyeongju, South Korea: effective use of S-wave polarizations retrieved from the high-density seismic array	Sangwoo HAN	M213	2024-08-27 10:45	2024-08-27 11:00	3126
Resolving rupture properties of small earthquakes in the southern Korean Peninsula using direct and reflected phases	Min-Seong SEO	M213	2024-08-27 11:00	2024-08-27 11:15	3121
Comprehensive Earthquake Parameter Determination using the AI and Bayesian Inference Techniques: Case Study on the Southeastern Korean Peninsula	Jongwon HAN	M213	2024-08-27 11:15	2024-08-27 11:30	3129
Teleseismic constraints on the crustal structure beneath Gyeongju, S. Korea from high-density seismic array data	Minkyung KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3133
The intricate fault interactions: source parameter estimation of the 2017 Pohang, Korea, earthquake and its aftershocks	Minkyung SON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3135
Seismic Properties of Upper-mantle 410- and 660-km Discontinuities Beneath the Korean Peninsula Using P-wave Receiver Functions	Juhyung LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3136

Title	Presenter	Venue	Start	End	Page
Constraining crustal composition of the continental China by three-dimensional Vp/Vs model	Guifang ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3137
Intraplate lithospheric structures near plate margins: comparison between northeast India (Eastern Himalayan Syntaxis) and southern Korean Peninsula	ABHISHEK KUNDU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3138
Deploying a Temporary Seismic Network for the 2022 Goesan Earthquake Sequence and its Integration with the Deep Learning Model EQTransformer	EunJin LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3139
Upper crustal azimuthal anisotropy and seismogenic tectonics of the Hefei segment of the Tan-Lu fault zone from ambient noise tomography	LI CHENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3140
Determination of moment magnitude of earthquakes in the Korean Peninsula from 2017 to 2022.	Yoontaek HONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3141
Recent seismicity in the Haenam and Suncheon regions using template matching method	Bohyun KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3142
Determination Focal Depth of the 2014 ML 5.1 Offshore Gyeongyeolbi Island Earthquake Using Depth Phase	Hyeonjun LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3143
Introduction to Research using the Unified Model for Subsurface Fault and Velocity Structure in the Korean Peninsula	Kyungmin MIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3144
Analysis of the three earthquakes with moment magnitudes greater than 4 in the Gunsan Basin, Yellow Sea, Korea, 2021	Miji KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3145
S5 The 2023 M7.8 and M7.5 Kahramanmaraş, Turkey, Earthquake Sequence		Session Chair: Tamer Y. DUMAN, YoungHee KIM			
[Keynote] The East Anatolian Fault System: An Overview on Active Tectonic Setting of the February 6, 2023, Kahramanmaraş Earthquake Sequence, Türkiye	OMER EMRE	M213	2024-08-27 14:30	2024-08-27 14:50	3147
[Keynote] Rupture Geometry and Segmentation associated with the 6 February 2023 Pazarcık (Mw 7.8) and Elbistan (Mw 7.6) Earthquakes: East Anatolian Fault, Southeastern Türkiye	Tamer Y. DUMAN	M213	2024-08-27 14:50	2024-08-27 15:10	3161
The Role of Stress Transfer in Earthquake Nucleation and Inhibition in the 2023 Kahramanmaraş, Türkiye, Earthquake Sequence	Shinji TODA	2024-08-27 10:00	2024-08-27 18:00	2024-08-27 15:25	3155
[Keynote] What determined the Rupture Extent of the 2023 Mw7.8 Kahramanmaraş Earthquake	Ali Ozgun KONCA	M213	2024-08-27 15:25	2024-08-27 15:45	3146
The 2023 Kahramanmaraş, Türkiye, earthquake doublet as the most powerful continental earthquake doublet: magnitudes, rupture process, triggering mechanism, and aftershocks	Xiaodong SONG	M213	2024-08-27 15:45	2024-08-27 16:00	3159
[Keynote] The earthquake deformation cycle along the East Anatolian Fault deduced from space geodesy; implications for rupture propagation and arrest	Ziyadin CAKIR	M213	2024-08-27 16:00	2024-08-27 16:20	3149
Stress perturbation induced by precedent earthquakes and its implications for the 2023 Kahramanmaras earthquake sequence	Junhyung Lee	M213	2024-08-27 16:45	2024-08-27 17:00	3156
Understanding the 2023 Mw 7.8 Pazarcık (Kahramanmaraş) Earthquake by integrating multi-parameter paleoseismological data from the Pazarcık segment of the East Anatolian Fault	Gülsen Ucarkus	M213	2024-08-27 17:00	2024-08-27 17:15	3157
Establishing and Operating the AFAD Earthquake Clearinghouse for Reconnaissance Efforts After the 6 February 2023 M7.7 and M7.6 Eastern Türkiye Earthquakes	RECEP CAKIR	M213	2024-08-27 17:15	2024-08-27 17:30	3150
Near-Fault and Off-Fault Field Observations of The 6 February 2023 Mw7.8 and Mw7.6 Kahramanmaraş and 20 February 2023 Mw6.4 Antakya earthquakes	Hasan SOZBILIR	M213	2024-08-27 17:30	2024-08-27 17:45	3153
A Comprehensive Analysis of Türkiye's Earthquake Disaster Response and Recovery Efforts Following the Devastating 6 February 2023 M7.7 and Mw7.6 Kahramanmaraş-Elbistan Earthquakes	Orhan TATAR	M213	2024-08-27 17:45	2024-08-27 18:00	3152
In the light of fault geometry, segmentation and slip distribution data an assessment of the February 06 2023 Pazarcık (Kahramanmaraş) earthquake (Mw 7.8), East Anatolian Fault Zone, Turkey.	Akın KÜRÇER	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3163
Rupture geometry and slip characteristics of the Doğanşehir Fault Zone rupture associated with the February 06, 2023 Ekinözü Earthquake (Mw 7.6), Eastern Anatolia, Türkiye	Hasan ELMACI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3165
Rupture Propagation Paths and Probabilities Considering Fault Continuity and Geometry in the 2023 Kahramanmaraş, Türkiye Earthquake	Yuki HARA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3167
Preliminary Study on Surface Rupture Displacement Analysis of the 2023 Kahramanmaraş(Turkey) Earthquake Using High-Resolution Optical KOMPSAT-3(A) Satellite	Chaehyeon CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3169
S6 Investigating subsurface structures with dense seismic array: Theories and applications		Session Chair: Hongyi LI			
Advanced seismic imaging of subsurface structures using wavelet-based decoupled wavefields on small aperture dense arrays	Hongfeng YANG	M213	2024-08-26 16:00	2024-08-26 16:15	3170
Subsurface structure imaging robustness enhancement with multiple processing methods on a dense seismic array	Lanbo Liu	M213	2024-08-26 16:15	2024-08-26 16:30	3171

Title	Presenter	Venue	Start	End	Page
Seismic velocity changes observed on a dense array of nodal seismometers reveal soil moisture changes in the Critical Zone	James HAMMOND	M213	2024-08-26 16:30	2024-08-26 16:45	3172
Unravelling crust-to-upper-mantle structures around the central Korean Peninsula using combined tomographic analyses	SEONGJUN PARK	M213	2024-08-26 16:45	2024-08-26 17:00	3174
Extraction of body waves from seismic ambient noise recorded by a dense seismic array at the Zhangbaling segment of Tanlu Fault Zone, China	Mingze DU	M213	2024-08-26 17:00	2024-08-26 17:15	3186
Lateral variation of the Mantle Transition Zone Beneath Southern Tibet inferred from receiver function analysis	YiBin WU	M213	2024-08-26 17:15	2024-08-26 17:30	3176
Pn-wave receiver function method	LiangYu ZHANG	M213	2024-08-26 17:30	2024-08-26 17:45	3177
Lithospheric Structure Beneath the Upper Indus Basin and its Adjacent Regions from Inversion of Surface Wave Dispersion	G.Suresh	M213	2024-08-26 17:45	2024-08-26 18:00	3175
Detailed crustal structure beneath the epicentral region of 2016 Mw 5.5 Gyeongju earthquake: preliminary results of teleseismic receiver functions from the Naenam Fault Array	Hobin LIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3178
The Seismogenic Processes of Main Faults in Sichuan-Yunnan Based on Time-varying Repeating Event Waveforms	Boyang WANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3179
The Characteristics of Regional Seismicity before the 2008 Mw 7.9 Wenchuan Earthquake	Xinzhong YIN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3181
Characterizing the shallow subsurface of the Bukpyeong Basin, Korea, by the HVSR method	SU YOUNG KANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3182
Fragmented Plates in Sumatra-Andaman Subduction Zone Revealed by Distinct Mantle Anisotropic Directions	BHASKARARAO ILLA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3183
Ambient Noise Tomography with a Short-Period Dense Array: Case of Sedimentary Basin	Hyejeong CHO	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3184
Deep Learning-driven ambient noise surface wave dispersion data selection along linear array	Yan WANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3185
Azimuthal anisotropy of the upper crust beneath the Gyeongju Hi-density Broadband Seismic Network rebuilt by the local shear wave splitting	June Baek	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3188
Investigation on the Influence of Non-uniform Noise Source Distribution on Ambient Noise Imaging Effectiveness	Fei HUANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3190
S7 Site survey and seismic safety for nuclear installations (Sponsor Special Session)		Session Chair: Korea Hydro & Nuclear Power Co., Ltd. (KHNP)			
[Keynote] Physics-based Ground Motion Prediction for Advanced Seismic Hazard Assessment: Potentials and Challenges	Seok Goo SONG	M213	2024-08-28 09:30	2024-08-28 09:45	3197
Procedure for the determination of Safe Shutdown Earthquake ground motion for nuclear power plants	Sinae HAN	M213	2024-08-28 09:45	2024-08-28 10:00	3195
Hybrid Empirical Ground Motion Predictions for the southern Korean Peninsula	Sae-Woon CHOI	M213	2024-08-28 10:00	2024-08-28 10:15	3194
Ground Motion Models for South Korea using the Hybrid Empirical Method and NGA-West2 Empirical Ground Motion Models	Seonjeong PARK	M213	2024-08-28 10:30	2024-08-28 10:45	3192
Investigation of Directional Variability of Earthquake Ground Motion of South Korea for Nuclear Seismic Safety Assessment	JEONGGON HA	M213	2024-08-28 10:45	2024-08-28 11:00	3193
Short and long-term behavioral characteristics of the Eupcheon Fault in the southeastern part of the Korean Peninsula	Sung-il CHO	M213	2024-08-28 11:00	2024-08-28 11:15	3191
Preliminary evaluation of fault activity around the southeastern part of the Korean Peninsula using probabilistic approach on seismogenic potential of a fault	Sung-il CHO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3198
Using logic-tree approach, reduction of uncertainty in fault source characterization for probabilistic seismic hazard analysis in South Korea	Sehyeon GWON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3199
The Study on the Seismic Source Parameters of Major Earthquakes in 2023	Hyun-Me RHEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3200
Shallow earthquakes in stable continental regions and implications for probabilistic seismic hazard analysis in SE Korea	Sehyeon GWON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3201
Development of Earthquake Ground Motion Database in Korea	Sang-hyun Lee	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3202
The high frequency spectral decay in seismic station near nuclear power plant using S wave autopicking.	Arim HAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3203
Application of High-Dimensional Visualization Techniques for the development of Ground Motion Characterization Model for the Korean Peninsula	Sae-Woon CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3204
Fault investigation through geomorphic analysis	Su-Ho JEONG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3205
Geological and Geotechnical Characterizations in the Arabian Gulf Coast	Yongwoo NOH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3206
S8+S4 General Topics		Session Chair: Scientific Program Committee			
On a numeric and interactive database for Algerian historical earthquakes	Radia KHERCHOUCHE	M213	2024-08-28 16:00	2024-08-28 16:15	3207
Ambient noise levels and their effects on the Pohang Community Seismograph Network (PCSN), South Korea	Yu Jin Sohn	M213	2024-08-28 16:15	2024-08-28 16:30	3212
Automatic earthquake detection using open source software	Nomin-Erdene ERDENETSOGT	M213	2024-08-28 16:30	2024-08-28 16:45	3211
Imaging the Aegean crustal structure using P and S phase travel times	Pratul RANJAN	M213	2024-08-28 16:45	2024-08-28 17:00	3210

Title	Presenter	Venue	Start	End	Page
Role of the Main Himalayan Thrust in generating earthquakes in the Himalaya	Devajit Hazarika	M213	2024-08-28 17:00	2024-08-28 17:15	3209
IMPLICATIONS ON THE PALEOSEISMICITY IN THE PRECAMBRIAN INTRACRATONIC BASINS: CASE STUDY OF THE BALTIC SEDIMENTARY BASIN	Jurga LAZAUSKIENĖ	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3214
Vector Autocorrelation and Cross Correlation for Resolution Improvement of Apparent Source Time Function	Wu-Cheng Chi	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3216
Estimation of seismic source parameters and high-frequency attenuation characteristic (Kappa) using microearthquake data in the southeastern Korean Peninsula	BYEONG SEOK AHN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3217
Seismic Noise in the Deep Underground Seismic Laboratory (JSTB): Influences from Mining Activity, Typhoons, and Precipitation	Do Woon KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3218
Determining Hypocenter of recent earthquakes in South Korea using the 3D velocity structure model and Antelope DB	Yeongjae CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3219
A Study on Earthquake Detection and Intensity Analysis Using High-Density MEMS Observation Network	EUNA PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3220
Case study on maximum seismic amplitude estimation for high-rise structures	Keun-Joo SEO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3221
Surface-to-borehole Site Correction: Assessing the suitability of transfer function	Jeongseon OH	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3222
Research on the identification of micro-seismic events in the Kangping area of Liaoning province based on random forest.	Zihao LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3224
Impact of data fidelity for double-difference relocation: A case study of the Kiskatinaw microseismic monitoring, British Columbia, Canada	Suhee PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3225
Tracking Typhoon Hinnamnor (2022) using microseism recorded at CTBTO seismic array	Yunah KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3227
Estimating Moment Magnitudes of Certain South Korean Macroseismic Events	SUNGSU KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3228
Seismicity in the South Korean Region Across Two Millennia	SEUNGHEE YUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3229
Comparing Acceleration and Velocity Horizontal-To-Vertical Spectral Ratios at South Korean Sites	Youngtaek HONG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3230
Comparing South Korean Earthquakes to Next Generation Attenuation West Ground Motion Models	Jungho KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3231
Comparing Peak Frequency to Shear Wave Velocity Models in South Korea	Joohwan CHA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3232
New insights of seismicity and stress pattern from the dense temporary deployment network in Anker, Kunene Region, Namibia	Bufelo Lushetile	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3233
Stratigraphic Analysis of Regressive Erosion in the Upper Coca River Basin: Insights from Seismic Imaging and Field Data	Christian WLADIMIR ROMERO CÓNDOR	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3234
Focal mechanisms of earthquakes in the Korean Peninsula based on P-wave first-motion polarity determination using deep learning	Ah-Hyun BYUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3235
T24 Geophysics					
S1 Fault detection and paleoseismology with near-surface geophysics		Session Chair: Takao Kobayhasi, Jin-Hyuck CHOI			
Detection of the buried rupture of the North Anatolian Fault in Kocaeli, Türkiye using ERT and VLF-R methods	Ümit AVŞAR	M212	2024-08-26 16:00	2024-08-26 16:15	3236
Geophysical investigation using ERT and MASW surveys at the Quaternary faults along the Yangsan fault system, SE Korea	Hwanwoo SEO	M212	2024-08-26 16:15	2024-08-26 16:30	3241
Structural characterization of intracratonic strike-slip faults in the southern Oridos Basin	Yunwen GUAN	M212	2024-08-26 16:30	2024-08-26 16:45	3238
GPR detection of buried paleo-channel through unconsolidated layer and characterization of the channel fill	Takao KOBAYASHI	M212	2024-08-26 16:45	2024-08-26 17:00	3239
Buried Geomorphic Signatures of Paleo-Earthquakes Detected by 3D GPR survey and Trench Analysis: A Case Study of the Yangsan Fault, South Korea	Changwan SUN	M212	2024-08-26 17:00	2024-08-26 17:15	3240
Detection of buried faults: a case study at the north end of the Miryang Fault, southeastern Korean Peninsula	Lanbo Liu	M212	2024-08-26 17:15	2024-08-26 17:30	3237
3D Imaging of Fault Fracture Zones using Electrical Resistivity Survey	Samgyu PARK	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3242
Utilizing Electrical Resistivity Method to Characterize Buried Faults in Suhari, Hong-Cheon, South	Jeong-Ryul CHOI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3243
Peering Through Sediments: Ground-Penetrating Radar Mapping of the Yangsan Fault	Hak Min LEE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3244
Understanding the subsurface structure of Bukpyeong Basin through 2-D electrical resistivity survey	WooHyun Kim	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3245
S2 Coupling of deep Earth and surface processes		Session Chair: Sang-Mook LEE, Haemyeong JUNG			
[Keynote] Pacific Array: an observational effort to find a link between the deep mantle process and surface features of the Pacific Basin	Hisashi UTADA	M212	2024-08-27 08:00	2024-08-27 08:30	3248
New Parameterization of Lithosphere-Asthenosphere System Beneath the Oldest Pacific Based on In-situ Seafloor Geophysical Observations	Hogyum KIM	M212	2024-08-27 08:30	2024-08-27 08:45	3255

Title	Presenter	Venue	Start	End	Page
A top-down control on upper crustal inheritance on the south-eastern Tibetan Plateau	Kun ZHANG	M212	2024-08-27 08:45	2024-08-27 09:00	3246
Lithosphere thermal structure of Greenland and Antarctica: Implications for the ice sheets dynamics –	Irina M. ARTEMIEVA	M212	2024-08-27 09:00	2024-08-27 09:15	3249
Geodynamic implications of small plume-driven weakening of the continental lithosphere	Ritabrata Dasgupta	M212	2024-08-27 09:15	2024-08-27 09:30	3251
Formation of the Continent and Surrounding Region from the Perspective of Changes in Subduction Configuration	SANG-MOOK LEE	M212	2024-08-27 09:30	2024-08-27 09:45	3253
Unraveling the diversity in arc volcanism and seismicity in Southwest Japan subduction zone: insights from numerical models	Goeun HA	M212	2024-08-27 09:45	2024-08-27 10:00	3254
Deformation microstructures of experimentally deformed epidote blueschist and implications for seismic low velocity layer and S-wave anisotropy in warm subduction zones	Yong PARK	M212	2024-08-27 10:00	2024-08-27 10:15	3252
Kinematics of Capricorn plate inferred from the GPS data relative to its surroundings region and possible Geodynamical implications	AKILAN A	M212	2024-08-27 10:15	2024-08-27 10:30	3250
GEOELECTRIC STUDY OF BARAK BASIN USING MAGNETOTELLURIC TECHNIQUE, NORTH-EASTERN INDIAN REGION	Devesh WALIA	M212	2024-08-27 10:30	2024-08-27 10:45	3256
Deformation fabrics of talc and chloritoid and implications for seismic anisotropy in subduction zones	Jungjin LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3257
Constraining Upper Mantle Seismic Anisotropy beneath the Oldest Pacific Seafloor from Shear-wave Splitting	Seung-Heon CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3258
Geodynamic Investigation of Subduction Angle and Possible Flat Subduction Beneath East Asia During Mesozoic	Kien PHAM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3260
Anomalous Inclination of Rock Samples from the South Atlantic Transect (SAT) and Their Implications for Variability in Magmatism of Slow-Spreading Ridges	Gilbert HONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3261
S3 New Insights into the evolution of Deccan Volcanic Province and its seismic scenario		Session Chair: Scientific Program Committee			
[Keynote] The Deccan Volcanic Province (DVP) of India hosts three different types of earthquake sequences	Harsh K GUPTA	M212	2024-08-27 14:30	2024-08-27 14:45	3266
Remnant mantle pathways of the Deccan volcanic eruption in the Indian subcontinent revealed by 3D magnetotelluric imaging	ABDUL AZEEZ KIZHAKKEKARA KUNJAVARAN	M212	2024-08-27 14:45	2024-08-27 15:00	3264
Tomographic imaging of sub-trappean Mesozoic sediments and basement configuration using long-offset seismic data in the Deccan Volcanic Province (DVP) of India	LAXMIDHAR BEHERA	M212	2024-08-27 15:00	2024-08-27 15:15	3267
Crustal geoelectrical structure of Koyna region, India: Role of fluids as inferred from magnetotelluric study	Bantu Prasanta Kumar PATRO	M212	2024-08-27 15:15	2024-08-27 15:30	3268
A RELOOK AT THE THICKNESS OF DECCAN TRAPS: IMPLICATIONS ON PALEOTOPOGRAPHY	VIVEK S. KALE	M212	2024-08-27 15:30	2024-08-27 15:45	3272
Crustal Architecture beneath southern Deccan Volcanic Province: Implications from Integrated Studies	Vasanthi ANTHWAR	M212	2024-08-27 15:45	2024-08-27 16:00	3274
Development of rift systems in the Kutch-Saurashtra region-A tale of multiple breakup events: Constraints from geophysical and geochronological data	Munukutla RADHAKRISHNA	M212	2024-08-27 16:15	2024-08-27 16:30	3276
Seismic imaging of southern part of Kachchh region (western India)	CHANDRAKALA KOTESWARA	M212	2024-08-27 16:30	2024-08-27 16:45	3275
Possible sub-surface extension of Deccan Magma in the north Arabian Sea	Vasanthi ANTHWAR	M212	2024-08-27 16:45	2024-08-27 17:00	3277
Constraining focal mechanisms of reservoir triggered seismicity in the Deccan Volcanic Province	D SHASHIDHAR	M212	2024-08-27 17:00	2024-08-27 17:15	3269
Bole beds and earthquake swarms in Deccan Volcanic Province, India	Rajender Kumar CHADHA	M212	2024-08-27 17:15	2024-08-27 17:30	3262
Characterization of 3D shallow subsurface structure of Deccan Volcanic Province, India using high frequency noise tomography	Sion Kumari Pasagadgu	M212	2024-08-27 17:30	2024-08-27 17:45	3265
Mid-crustal basement below Deccan Volcanic Province: Evidence from multiparametric borehole study	Om Prakash PANDEY	M212	2024-08-27 17:45	2024-08-27 18:00	3270
Tectonomagmatic evolution of the crust and lithosphere beneath the Western Deccan Volcanic Province, India – A magnetotelluric study	Pavankumar GAYATRI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3278
Delineation of lithospheric structure across the Deccan Volcanic Province and Eastern Dharwar Craton, south Indian shield using joint inversion of receiver function and surface wave dispersion data	Sudesh KUMAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3279
Configuration of Deccan Traps and its effect on triggered seismicity in Koyna-Warna Seismic Zone, India	Ujjal BORAH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3280
Deep Seismic Reflection Profiling across the Seismically active Mesozoic Kachchh rift basin, NW India: implications for crustal evolution	BISWAJIT MANDAL	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3281
Paleomagnetism of KBH-7 core from Koyna, Western Ghats, India	Venkateshwarlu MAMILLA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3282

Title	Presenter	Venue	Start	End	Page
Secondary mineralization and fluid channelization through fractures within the basement rocks of seismically active Koyna-Warna area, Maharashtra, India	Manas GOSWAMI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3283
S6+S4+S5 Trending Machine Learning Applications in Oil and Gas Industry		Session Chair: Scientific Program Committee			
Application of supervised neural network algorithm in logging predicting shale lithofacies - A case study from the first member of Qingshankou Formation in Gulong Sag, Songliao Basin	danting LUO	M212	2024-08-28 08:00	2024-08-28 08:15	3285
A review of the utilization of novel artificial intelligence tools for advanced reservoir characterization	SHIB SANKAR GANGULI	M212	2024-08-28 08:15	2024-08-28 08:30	3286
Blank strip filling method for electrical logging images based on the combination of convolution neural network and Transformer	XU PANG	M212	2024-08-28 08:30	2024-08-28 08:45	3284
Appraisal of gas hydrate saturation in KG basin using synergistic implementation of geophysical log analysis and machine learning approaches	SUMAN KONAR	M212	2024-08-28 08:45	2024-08-28 09:00	3287
Fine Structure Description and Hydrocarbon Prediction of Fault-karst Reservoir	Hong ZHANG	M212	2024-08-28 09:00	2024-08-28 09:15	3288
Quantification of uncertainty in the reconstruction of resistivity tomography image with machine learning	Xixi LAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3290
Identification Method Of Micro Residual Oil Types And Quantitative Characterization Based On Deep Learning	Xianda SUN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3291
S7 General Topics		Session Chair: Scientific Program Committee			
Characterizing electrical properties of hydrate-bearing sediments during dissociation via 3D multifield-coupled numerical simulation	Xixi LAN	M212	2024-08-28 09:30	2024-08-28 09:45	3295
Structure of the Denizli Graben-Horst System & Acıgöl Graben in the Western Anatolian Extensional Province from magnetotelluric resistivity models.	Ümit AVŞAR	M212	2024-08-28 09:45	2024-08-28 10:00	3296
2-D Integrated Geophysical Modelling Over an Anomalous Magnetic Body in North-Western Bangladesh	XixiLAN	M212	2024-08-28 10:00	2024-08-28 10:15	3297
A novel method of seismic data reconstruction in reverse time migration	YueZHENG	M212	2024-08-28 10:15	2024-08-28 10:30	3293
Particle Swarm Optimization - Gravitational Search Algorithm Tuned Deep Neural Network to estimate the subsurface interlayer boundary	Sunam KumarSHARMA	M212	2024-08-28 10:30	2024-08-28 10:45	3292
Oscillatory constituents of the secular variation of the geomagnetic field	CrișanDEMETRESCU	M212	2024-08-28 10:45	2024-08-28 11:00	3298
Investigation of fluid gas migration with an insight of mineralization using Amplitude vs Offset analysis for offshore Multichannel Seismic reflection Data	DEBAJYOTI SAHA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3299
The density structure of the around Gyeongju based on gravity analysis	Young-Cheol Lee	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3300
Neotectonic deformation in the southwestern part of the Anatolian Block in consideration of palaeomagnetic results in Bodrum peninsula.	Ümit AVŞAR	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3302
Seismic Fine Description of Facies Change Reservoir in Subei Basin	Zhipeng Gui	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3303
Improved C3 coherence algorithm considering structure dip without interpolation	ZiCheng Wang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3305
MODERN GEOELECTRIC MODEL OF GROUNDWATER FILTRATION FLOWS AND ITS SEARCH VALUE	Rakhimjan TURSUNMETOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3307
Generalized linear inversion of prestack data based on exact Zoeppritz equation	Guobin HU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3309
Optimized spectral decomposition method based on Restart and Adaptive Rapid Iterative Shrinkage Threshold	Jifei Qi	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3310
Analytical study of geomagnetic observations using automated absolute measurements collected in 2023 at the Cheongyang Geomagnetic Observatory in South Korea.	Sohyeon Park	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3311
T25 Geotechnology and Geophysical Exploration					
S1 Advances in Geophysical Exploration Techniques for Resource Characterization		Session Chair: Scientific Program Committee			
[Keynote] Identification of prospective regions for selected critical minerals through integrated geophysical, geochemical and geologic data	Carol A FINN	M212	2024-08-29 14:00	2024-08-29 14:15	3320
A seismic geomorphology study of the fluvial and shallow-delta facies of the Oligocene Huagang Formations in the East China Sea Shelf Basin, China	Huafeng LIU	M212	2024-08-29 14:15	2024-08-29 14:30	3315
Research On The Frontier Technology Of Continuous Coring For Directional Drilling	Yinlong MA	M212	2024-08-29 14:30	2024-08-29 14:45	3317
Research on Anti-Adhesion and Drag Reduction Performance of Bionic Sampling Tube for Shallow Submarine Sediments	Pengyu ZHANG	M212	2024-08-29 14:45	2024-08-29 15:00	3318
Microscopic structure and wear properties of micro-nano sized (TiCp-SiCp)/ 7075Al composites	Yueqi LI	M212	2024-08-29 15:00	2024-08-29 15:15	3319

Title	Presenter	Venue	Start	End	Page
Identification of River Sand Body Based on Deep Residual Shrinkage Network	yufei SU	M212	2024-08-29 15:15	2024-08-29 15:30	3322
New progress in research of lightweight wear-resistant drilling pipe materials	Shaoming MA	M212	2024-08-29 15:30	2024-08-29 15:45	3323
Deterministic Approaches and Machine Learning Approaches for fluid detection: a comparison and integration	Mohammed FARFOUR	M212	2024-08-29 15:45	2024-08-29 16:00	3313
Use of geochemical and ground magnetic data in the definition of copper-cobalt targets in the blind area. A case study: Kanseba prospect.	Naveen BHADU	M212	2024-08-29 16:00	2024-08-29 16:15	3314
Enhancing Reservoir Performance Prediction Through Advanced Data Analytics and Machine Learning: A Study on Reservoir Evaluation Management for Improved Oil and Gas Recovery in the Orange Basin, Namibia.	Freddie KAFULA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3324
The application of comprehensive electromagnetic methods in the search for copper-nickel polymetallic ores in shallow-covered areas-A case study of the Jing'erquan area in the East Tianshan Mountains of Xinjiang	ShiHao JIA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3325
An efficient 3D inversion algorithm for the inversion of large-scale magnetic dataset when remanence exists	Jun WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3327
Accurate first arrivals picking method combining dynamic threshold control and bisection in complex geological environment.	Hongyan Yan	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3328
S-wave propagation and analysis under the modified couple stress theory	Wenlei BAI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3329
Improving Seismic Profile Resolution through Inversion of Reflection Coefficients based on Short-Time Fourier Transform and Restarted Fast ADMM	Wei SONG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3330
Wave propagation and analysis under the single-parameter second-order strain gradient theory	Chaopu CHEN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3331
S2+S3 Geotechnology and its Applications in Geological Hazard Assessment and Monitoring		Session Chair: Scientific Program Committee			
Nuclear magnetic resonance constrained triple-water resistivity model to estimate the fluid saturation in Zao 34 block, Bohai bay basin	XueJuan ZHU	M212	2024-08-29 16:45	2024-08-29 17:00	3340
A holistic approach towards geophysical characterization of the Quick Clays in Norway; A case study from Gjerdrum	Saman Tavakoli	M212	2024-08-29 17:15	2024-08-29 17:30	3333
Multi-thematic geoscience study in Hamirgarh Bhiyana segment, eastern Aravalli Craton Rajasthan, Western India: Evidences of existence of dual mineral systems	Rana BANDYOPADHYAY	M212	2024-08-29 17:30	2024-08-29 17:45	3338
Slope Failure Back Analysis from Ground-Based Radar Data to Estimate the Safe Re-entry Time After Failure	Dio Yudha PRATAMA	M212	2024-08-29 17:45	2024-08-29 18:00	3336
Interpretation of aero-magnetic ring features in Sausar fold belt, Bastar Craton, Central India	SHEIKH MOHAMMAD SHAKIL HASHMI	M212	2024-08-29 18:00	2024-08-29 18:15	3334
Proximity Excavation in Down Town area Using High Tension Net	BYUNG DON RO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3342
Correlation between consolidation of soft ground and time-lapse gravity	YeongJae LEE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3343
Gravity and Gravity Gradient Joint Fast Inversion Method	Zhengyuan JIA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3344
Distribution of plume-shaped low-gravity zone in the southeastern part of the Korean Peninsula estimated through 3D gravity modeling	sung-wook KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3345
Investigation on the magnetotelluric (MT) survey from the Yeonil Tectonic Line and Ulsan fault zones in the Gyeongsang Basin of Korea	Kyeongho Ryu	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3346
T26 Geoscience Education					
S1 Geology Degrees Across the World – How are the Next Generation of Geologists Being Educated for the Geosciences of Tomorrow		Session Chair: Scientific Program Committee			
PROFESSIONAL INITIATION RESIDENCE PROGRAM LATO-SENSU IN EARTH SCIENCES AT THE GEOLOGICAL SURVEY OF BRAZIL – CPRM	Patricia DURINGER Jacques	M215	2024-08-28 08:00	2024-08-28 08:15	3348
ERASMUS+: a strategic tool to build partnerships among continents to enhance Geoscience through Higher Education.	Lola PEREIRA	M215	2024-08-28 08:15	2024-08-28 08:30	3350
Towards a common understanding of raw materials education worldwide – An international Qualification Framework for Raw Materials	Vitor Correia	M215	2024-08-28 08:30	2024-08-28 08:45	3352
Vision and Change – Transforming Geoscience Education in the United States	Christopher KEANE	M215	2024-08-28 08:45	2024-08-28 09:00	3353
Geoscientists for Ireland's future – What are we doing to encourage their creation?	Siobhán Eilís Power	M215	2024-08-28 09:00	2024-08-28 09:15	3354
The role of the NATIONAL FORUM OF GEOLOGY COURSES IN BRAZIL in the training of geologists and geological engineers	Alexis Rosa NUMMER	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3355
Enhancing Geoscience Education Through Critical Thinking: Insights on Teacher Development and Student Engagement	Liang Qiu	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3356
S2 Exploring Geoscience Across the Globe: Special Session in Memory of Chris King		Session Chair: Scientific Program Committee			
Promoting Geoscience Education in a South African Science Centre	Tanja REINHARDT	M215	2024-08-28 10:00	2024-08-28 10:15	3357

Title	Presenter	Venue	Start	End	Page
Teaching with toilet roll and learning with LegoTM to address the geosciences knowledge and skills gaps in the UK and beyond. -Teaching in the shadow of a king	Phillip MURPHY	M215	2024-08-28 10:15	2024-08-28 10:30	3358
Geoscience outreach for visually impaired learners: A journey to “see” Earth and space differently	Tanja REINHARDT	M215	2024-08-28 10:30	2024-08-28 10:45	3359
The Transformative Power of International Geoscience Experiences for Students	Tara Schielein	M215	2024-08-28 10:45	2024-08-28 11:00	3360
Sharing outreach and educational materials through YouTube: a case study from the Shear Zone Channel.	Rob BUTLER	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3361
Participatory Photography Methods in Geoscience Education	Sharon LOCKE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3363
S4 International perspectives for natural disaster education		Session Chair: Scientific Program Committee			
[Keynote] Systematization of Education for Disaster Risk Reduction from the Viewpoint of SDGs	Tatsuya FUJIOKA	M215	2024-08-28 16:00	2024-08-28 16:15	3368
UK Perspectives on Educating for "No Natural Disasters"	ILAN KELMAN	M215	2024-08-28 16:15	2024-08-28 16:30	3364
Incorporating Natural Blessings and Disasters to Develop an Integrated School Curriculum	Hisashi OTSUJI	M215	2024-08-28 16:30	2024-08-28 16:45	3365
Natural Disaster and Education in South Korea	Young Shin Park	M215	2024-08-28 16:45	2024-08-28 17:00	3366
Current Status and Issues of Earthquake Disaster Prevention Education in a Major City that Experienced The 1995 Southern Hyogo Prefecture Earthquake: A Case Study of Kobe City	Toshio ARIMICHI	M215	2024-08-28 17:00	2024-08-28 17:15	3370
Educating Local Communities in the Southeastern USA through a Natural Hazards Course	Athena Owen NAGEL	M215	2024-08-28 17:15	2024-08-28 17:30	3371
Development of Volcano Disaster Prevention Education Program from the Perspective of STEAM Education	Shintaro SATO	M215	2024-08-28 17:30	2024-08-28 17:45	3372
Examples of SDGs that raise awareness of disaster prevention and mitigation in schools and local communities.	Ichiro MATSUMOTO	M215	2024-08-28 17:45	2024-08-28 18:00	3374
S5 Geoscience Education and Outreach for All: Techniques and Trends for Engaging Non-Specialist Learners		Session Chair: Scientific Program Committee			
Exploring Learning in Virtual Geological Field Trip: A Theoretical Approach Based on the Revised Novelty Space Concept	YOONSUNG CHOI	M215	2024-08-29 08:00	2024-08-29 08:15	3375
Anthropomorphic characters: “Lucky charms - Geo-Mascots – Geo-Cartoons – Geo-Emoji Mascots” in Geoscience communication and popularisation	Maria-Luise Luise FREY	M215	2024-08-29 08:15	2024-08-29 08:30	3376
Understanding time scales: which teaching materials do students find easier to understand? - Cosmic (Geologic) Ticker Tape, Cosmic (Geologic) Calendar, and Cosmic (Geologic) historical film in case of undergraduate students –	Hiroo NEMOTO	M215	2024-08-29 08:30	2024-08-29 08:45	3378
Elementary Students' Understanding of Fossil Formation and Geological Change	Younkyeong Nam	M215	2024-08-29 08:45	2024-08-29 09:00	3382
Promoting Use of the UN Sustainable Development Goals in Pre-college Geoscience Education	Ed C. Robeck	M215	2024-08-29 09:00	2024-08-29 09:15	3383
Earth of all, Geology for all	Michele LUSTRINO	M215	2024-08-29 09:15	2024-08-29 09:30	3384
Geology and Disaster Risk Reduction Training for Non-Specialist Science Teachers: Implications for Professional Development of Teachers	Magnolia Vida Ante CANO	M215	2024-08-29 09:30	2024-08-29 09:45	3387
Communicating like Hutton and Muir: Connecting geology and ecology (Geocology) to improve public support for critical raw material extraction	Maureen Gallagher	M215	2024-08-29 09:45	2024-08-29 10:00	3386
Geodyssey: Forging a new path for app-based geoscientific teaching and learning	Cameron Roy PENN-CLARKE	M215	2024-08-29 10:00	2024-08-29 10:15	3380
The Geological History of Colombia Told by Its Rocks	Vanessa Rey León	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3389
Advancing geography education through 3D geospatial information	yuichi S. hayakawa	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3391
Sandsnap: Engaging the Public in Coastal Geoscience Through Social Media and Education Outreach	Brooke Marlo WALKER	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3392
Role-Playing: A New Method for Museum Exhibitions , (A Case Study from the Liu Guanghua Museum of Natural Heritage)	ZHUQING DENIS DING	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3393
Geolchat Fossil Edition: Using Paleontology as an science outreach strategy in social media	María Daniela MUÑOZ-GRANADOS	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3394
School Rock Maps: Geological information translated for society by the Geological Survey of Brazil	Andrea SANDER	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3396
Popularizing Brazilian paleontology through fossil replica workshops at the Geological Survey of Brazil	Andrea SANDER	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3398
Dissemination of Geosciences: SGBeduca's teaching collection of minerals and rocks donated to teachers	Andrea SANDER	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3400
S6 Geoscience Education and Awareness		Session Chair: Scientific Program Committee			
GEOLOGISTS.COM—the global digital platform fostering communication and collaboration among geologists and other professionals across Earth science disciplines	Olena IVANOVA	M215	2024-08-30 08:00	2024-08-30 08:15	3402

Title	Presenter	Venue	Start	End	Page
The importance of informal educators in improving geoscience education in Namibia	Josephine UUSHONA	M215	2024-08-30 08:15	2024-08-30 08:30	3406
REGIONAL DRILL CORE REPOSITORY, GSI, NAGPUR: A CENTRE FOR GEOSCIENCE INFORMATION DISSEMINATION	praveer PANKAJ	M215	2024-08-30 08:30	2024-08-30 08:45	3404
The Importance of Science Communication About Hydrogeology in Culturally Sensitive Arid Areas	Barbara REYES	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3408
Interpreting Dragons and Dinosaurs: Gaining Insights Through Museum Initiatives (Exhibition Practices at the Liu Guanghua Museum of Natural Heritage)	ZHUQING DING	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3409
ALTERNATIVE E-ASSESSMENT WITH INTEGRATED ACADEMIC STUDENT SUPPORT: CASE STUDY- ENVIRONMENTAL SCIENCES	Helena VAN NIEKERK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3411
S7 Mitigating multi-hazard risks: perception, awareness and educational perspectives to cultivate a risk culture and strengthen disaster resilience in vulnerable communities		Session Chair: Scientific Program Committee			
Conceptions of risk in the face of crises and the memory of events in tropical island territories. Ways of establishing a risk culture in the French West Indies.	Yves MAZABRAUD	M215	2024-08-30 09:30	2024-08-30 09:45	3412
Strategies and challenges for risk education in the city of São Paulo, Brazil	Natalia Leite de MORAIS	M215	2024-08-30 09:45	2024-08-30 10:00	3415
Languages and natural risk prevention in diglossic territories: a study in Guadeloupe	Béatrice JEANNOT-FOURCAUD	M215	2024-08-30 10:00	2024-08-30 10:15	3414
Deciphering the Scientific Conceptions of Students and Teachers: from Interaction-Based Modelling to Machine Learning Perspectives.	Alexandra RENOUARD	M215	2024-08-30 10:15	2024-08-30 10:30	3413
CREDO-L: An Innovative Landslide Mitigation Strategy for Highschool Students (Study Case: Depok, Indonesia)	TWIN HOSEA WIDODO KRISTYANTO	M215	2024-08-30 10:30	2024-08-30 10:45	3417
S8 International Perspectives on Earth Science Education		Session Chair: Scientific Program Committee			
Over 20 years of serving secondary and tertiary education worldwide – The activities of the Education Committee of EGU	Friedrich BARNIKEL	M215	2024-08-29 14:30	2024-08-29 14:45	3418
Measuring and Communicating the Impact of Earth Science Research on Society and the United Nations Sustainable Development Goals	Phoebe MCMELLON	M215	2024-08-29 14:45	2024-08-29 15:00	3420
Between Fieldwork and Classroom Training: the School of Geology and the Early Geological Survey in China (1913-1916)	Lijuan YANG	M215	2024-08-29 15:00	2024-08-29 15:15	3422
Fostering geoheritage education through Virtual Reality technologies	Vittoria VANDELLI	M215	2024-08-29 15:15	2024-08-29 15:30	3423
Practice of Geoscience Education for Guilin Karst World Natural Heritage Site -- Taking "A Drip of Water Travel" as an Example	Lina SHEN	M215	2024-08-29 15:30	2024-08-29 15:45	3428
Philippine Participation in the International Earth Science Olympiad (IESO): A Longitudinal Study	Miguel CANO	M215	2024-08-29 15:45	2024-08-29 16:00	3427
Evolution and Achievements of the IUGS Commission on Geoscience Education (COGE)	Ian Francis CLARK	M215	2024-08-29 16:00	2024-08-29 16:15	3425
[Keynote] Engaged Geosciences: Connecting Students, Teachers, and Community to Solve Local and Global Problems	Sharon LOCKE	M215	2024-08-29 16:30	2024-08-29 16:45	3429
Arts and Geoscience: An Interdisciplinary Approach to Enhancing Geoscience Education	Sandra Paula VIILLACORTA CHAMBI	Exhibition Hall			3430
Mobilizing Geoscience Education: The Mobile Laboratory (Laboratorio Móvil - LAM) Experience in Rural Uruguay	Elena Peel	Exhibition Hall			3432
S9 General Topics		Session Chair: Scientific Program Committee			
CLIMATIC DYNAMICS AND POPULATION TRENDS OF MICROTUS (IBEROMYS) CABRERAE (THOMAS, 1906) IN THE MEDITERRANEAN: A BIOCLIMATIC NICHE MODELING APPROACH	JULIA JIMENO-ALDA	M215	2024-08-30 13:50	2024-08-30 14:05	3433
Evaluation of Interpolation Methods for Mapping Potential Hydrogen for Windhoek Municipal Boreholes	Taleni Silas Taleni David	M215	2024-08-30 14:05	2024-08-30 14:20	3435
Promoting the equality of research and education in geosciences using 3D digital outcrops: implications of the DDE-Outcrop3D platform	Xia WANG	M215	2024-08-30 14:20	2024-08-30 14:35	3436
The why and how of seismic and geomechanical approaches for effective reservoir characterization	SHIB SANKAR GANGULI	M215	2024-08-30 14:35	2024-08-30 14:50	3437
Science Diplomacy in Action: Unveiling Opportunities and Challenges – A Case Study of Namibia's Endeavor to Integrate Science and Politics	Martha Ndapandula Haludilu	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3438
Erosion, Transport, and Deposition of Microplastics	Ino-Ethandje Thomas	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3439
The subsurface of Valencia: Conceptualization and 3D high-resolution model	ARIADNA CALLEA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3440
PETROGRAPHIC CHARACTERIZATION AND DIAGENESIS OF CARBONATE ROCKS IN THE NAMA BASIN OF SOUTHERN NAMIBIA: IMPLICATION AS VALUABLE RESOURCES.	Sam Shihafeleni SHANGHETA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3441

Title	Presenter	Venue	Start	End	Page
Re-assessing late Holocene Lake level fluctuations in Lago Cardiel, Southern Patagonia (Argentina) – Geomorphological and archeological implications.	Luis Rubén Horta	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3442
Neoichnology in Salar de Antofalla, Catamarca province, Argentina: a study case of Diptera living in an extreme environment	Gabriel Ricardo LÓ PEZ ISLA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3443
DECIPHERING THE LIMITS OF HABITABILITY: GEOSPATIAL ANALYSIS OF ANDEAN MICROBIALITIC SYSTEMS AS ANALOGUES FOR THE SEARCH FOR LIFE ON MARS.	Micaela DELLA VEDOVA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3445
Geochemical, isotopic, and mineralogical study of Vega Verde travertine system, central Andes -Argentina.	Guido Ezequiel Alonso	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3446
T27 Geoheritage, Geopark, and Geotourism					
S1+S2 Heritage Stone: safeguarding the cultural and social legacy of rocks		Session Chair: Víctor Cárdenes Van den EYNDE, Angela Ehling			
Trail of Heritage Stones along the trade routes through the ages	Angela EHLING	M211	2024-08-29 08:00	2024-08-29 08:15	3450
Portuguese limestones from the Middle Jurassic of the MCE candidate for heritage stone	Luis LOPES	M211	2024-08-29 08:15	2024-08-29 08:30	3452
A New Approach to Key Mineral Analysis for Tracking the Provenance of Stone Heritage	Myoungju CHOIE	M211	2024-08-29 08:30	2024-08-29 08:45	3458
A new look at the geology collections of the National museum of natural history - Paris, heritage stones from buildings or sites	Grégoire EGOROFF	M211	2024-08-29 08:45	2024-08-29 09:00	3453
Heritage Stone Subcommission: Showcasing the first 50 IUGS Heritage Stones	VINOD KUMAR SHARMA	M211	2024-08-29 09:00	2024-08-29 09:15	3462
Heritage Stones, and their cultural and historical legacy in the Indian subcontinent	VINOD KUMAR SHARMA	M211	2024-08-29 09:15	2024-08-29 09:30	3448
GOREE ISLAND (Dakar, Senegal, West Africa), UNESCO World Heritage Site without GEODIVERSITY ? Inventory AND Assessment of a GEOMORPHOSITE Sensitive to Coastal Erosion	Cheikh Ibrahima YOUM	M211	2024-08-29 09:30	2024-08-29 09:45	3463
The natural stones of the cemeteries in the PNDO (Ardennes, Wallonia, Belgium): a geoheritage approach linking geodiversity and biodiversity	Xavier DEVLEESCHOUWER	M211	2024-08-29 09:45	2024-08-29 10:00	3460
Geoheritage value of the Fonte Fenix and the Boca de Vaca springs from Panjim: hidden jewels from Goa, India	Raymond Ashirwad DURAISWAMI	M211	2024-08-29 10:00	2024-08-29 10:15	3456
Cultural and Social Legacy of Alpedrete Granite Heritage Stone	David Martín FREIRE-LISTA	M211	2024-08-29 10:15	2024-08-29 10:30	3454
SOCIAL LICENSE TO OPERATE FOR HERITAGE STONES QUARRIES: IS THIS APPROACH POSSIBLE?	Paola MARINI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3464
Itria Valley Heritage stones: the new studies on Natural Stone and World Heritage for the Apulian limestones	Paola MARINI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3465
S3 Geosites and Georoutes in the History of Geological Sciences		Session Chair: Ezio VACCARI, Martina KÖLBL-EBERT			
[Keynote] IUGS Geological Heritage Sites. A recognition to the history of our science	Asier Hilario	M211	2024-08-30 08:00	2024-08-30 08:15	3473
Crossing Heritages. Geosites, Geoheritage and their History through Images	Maddalena NAPOLITANI	M211	2024-08-30 08:15	2024-08-30 08:30	3466
VESUVIUS GEOROUTES	Claudia Principe	M211	2024-08-30 08:30	2024-08-30 08:45	3472
Maruia Falls (New Zealand) – a Historical Geosite for the Discovery of the Inner Earth Core	Martina KÖLBL-EBERT	M211	2024-08-30 08:45	2024-08-30 09:00	3467
Archibald Geikie and Edward Hull Tour 1887: in search of historical georoutes and geosites in County Donegal (Ireland)	Catherine (Kathleen) HISTON	M211	2024-08-30 09:00	2024-08-30 09:15	3469
The Agno Valley and Giovanni Arduino's 1758 cross section: an iconic site and a classic image for the birth of lithostratigraphy	Ezio VACCARI	M211	2024-08-30 09:15	2024-08-30 09:30	3468
MONTE AMIATA (TUSCANY, ITALY) IN THE HISTORY OF VOLCANOLOGY	Claudia Principe	M211	2024-08-30 09:30	2024-08-30 09:45	3470
The Argonauts Campaign to the Ancient Colchis Kingdom: One of the first documented geological exploration in the Human history	Avtandil OKROSTSVARIDZE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3475
Digital Preservation and Sharing of Classic Geosites and Georoutes via DDE-Outcrop3D Platform	HANTING ZHONG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3477
S4 Geoconservation and Geoheritage: geodiversity underpinning natural systems		Session Chair: Kevin Page, John Gordon			
[Keynote] Conservation of geodiversity and geoheritage in protected and conserved areas underpins natural systems and contributes to a sustainable future	John E. Gordon	M211	2024-08-27 09:30	2024-08-27 09:45	3502
The current status of geoheritage management in Korea: a decade of progress and future directions	Wansang RYU	M211	2024-08-27 09:45	2024-08-27 10:00	3492
How can we arrange a geoconservation strategy in our area? some tips based in the Basque Country (Spain).	Manu R. MONGE-GANUZAS	M211	2024-08-27 10:00	2024-08-27 10:15	3487
Integrating geoconservation and sustainability: a focus on natural resource management in the Brazilian Amazon	MARIA DA GLORIA GARCIA	M211	2024-08-27 10:15	2024-08-27 10:30	3488

Title	Presenter	Venue	Start	End	Page
Geoheritage and Geoconservation as a resource and a tool for promoting the United Nations 17 Sustainable Develop Goals (SDGs)	Kevin Neil Page	M211	2024-08-27 10:30	2024-08-27 10:45	3493
Managing natural heritage: geoconservation efforts across Latin America and the Caribbean's landscapes	MARIA DA GLORIA GARCIA	M211	2024-08-27 10:45	2024-08-27 11:00	3485
New geoheritage research initiative of the Saudi Geological Survey aiming to act as national guardian of the abiotic natural values of the Kingdom of Saudi Arabia	Karoly NEMETH	M211	2024-08-27 14:30	2024-08-27 14:45	3503
Key Geoheritage Areas: a promising IUCN initiative for global geoconservation	José B. R. BRILHA	M211	2024-08-27 14:45	2024-08-27 15:00	3500
Geoparks' way of survival in National Parks management system-perspectives from Australia and China	Qian Li	M211	2024-08-27 15:00	2024-08-27 15:15	3497
The open air Museum - A significant geoconservation in the Lesvos Petrified Forest - Lesvos island UNESCO Global Geopark, Greece.	Nikolaos ZOUROS	M211	2024-08-27 15:15	2024-08-27 15:30	3482
From Cultural Landscape to Aspiring Geopark: 18 Years of Community-Based Landscape Tourism Development in Fengnan Village, Hualien County, Taiwan (2006–2024)	Kuang Chung LEE	M211	2024-08-27 15:30	2024-08-27 15:45	3480
Geosensitivity based Geoheritage threat mapping using RS and GIS in the Darjeeling hill region, India	Lakpa TAMANG	M211	2024-08-27 15:45	2024-08-27 16:00	3484
Integrating geo- and biodiversity: Towards a more holistic approach to nature conservation	Kevin Neil Page	M211	2024-08-27 16:00	2024-08-27 16:15	3495
Addressing geohazards in populated geoheritage sites: the case of Dovžan Gorge Natural Monument in Slovenia	Matevž Novak	M211	2024-08-27 16:30	2024-08-27 16:45	3490
When citizens contribute to the discovery of geosites and to geoconservation	Isabelle ROUGET	M211	2024-08-27 16:45	2024-08-27 17:00	3498
From Cultural Landscape to Aspiring Geopark: 18 Years of Community-Based Landscape Tourism Development in Fengnan Village, Hualien County, Taiwan (2006–2024)	Kuang Chung LEE	M211	2024-08-27 17:00	2024-08-27 17:15	3480
Remote sensing assessment of biological activities on built historical structures in a tropical region: Case of the Osun-Osogbo Sacred Grove UNESCO World Heritage Site, South-Western Nigeria.	Jokotola Toyyebat OMIDIJI	M211	2024-08-27 17:15	2024-08-27 17:30	3478
How to save a discovery in an active mine? Cooperation with the mine and its workers to protect the dinosaur heritage	Piotr SZREK	M211	2024-08-27 17:30	2024-08-27 17:45	3505
Toward global modelling of geoheritage and geodiversity loss	Mihai Niculiță	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3506
Interpretation of Underground Structure and Provenance for Rock Properties in Three-story Stone Pagoda and Flagpole Support Stones from Jungchosaji Temple Site of Anyang, Korea	HyeJi Choi	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3507
U.S. Geological Survey Geoheritage Sites of the Nation Inventory	Christina DEVERA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3509
Lithological Characteristics and Provenance Interpretation of Stone Properties for Jotap-ri Five-story Brick Pagoda in Andong, Korea	Dong Hee JEONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3511
Stability Interpretation for Rock-carved Standing Buddha Triad of Dongmun-ri in Taean, Korea, based on Geophysical Exploration and Slope Analysis	ILKYU CHOI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3513
Provenance Interpretation and Petrological Characteristics from Hongjueupseong Fortress Wall and Stone Block Foundation of Joyangmun Gate in Hongseong, Korea	JUN HO SONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3515
Cultural ecosystem services as a good presentation of geodiversity in the geopark– A case study in Taitung Geopark, southeast Taiwan	Chuanyao CHI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3517
Integrated geological and geophysical monitoring of the Udo beach sediments (Natural Monument) for geoheritage conservation	WOOSEOK YOON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3518
Can computational geoscientists and digital innovation contribute to geoconservation strategies?	Antoine BOUZIAT	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3519
S6 Geoscience in Geoheritage, Geoparks and Geotourism		Session Chair: Afia Akhtar			
Exploring Hydrogeochemical Characteristics and Impact on Geoheritage Monuments in Odisha: A GIS and Statistical Approach	ROSALIN DAS	M211	2024-08-29 14:30	2024-08-29 14:45	3533
Preserving Belitong Island UNESCO Global Geopark Unique Heritage: Geomorphosites and Anthropogenic Landforms	Santi Dwi PRATIWI	M211	2024-08-29 14:45	2024-08-29 15:00	3522
Sustainable use of materials from an abandoned quarry in a Unesco Global Geopark in Spain. A proposal.	Lola PEREIRA	M211	2024-08-29 15:00	2024-08-29 15:15	3524
Paleontological Zoning: a new paradigm for geoconservation in the Uberaba Geopark, Brazil	Thiago da Silva MARINHO	M211	2024-08-29 15:15	2024-08-29 15:30	3526
Investigation and Promotion of Geological Heritage of the Karaburun Peninsula in Türkiye	Oyküm Berfin GULERGUL	M211	2024-08-29 15:30	2024-08-29 15:45	3531
The Geological Setting of Tanzania with Possibilities of Hosting Potential Geoparks Worldwide	John Desderius Kalimenze	M211	2024-08-29 15:45	2024-08-29 16:00	3528
Geoheritage and Geotourism prospect of Ramu Upazila Cox's Bazar District, Bangladesh	Md. Faruk HASAN	M211	2024-08-29 16:00	2024-08-29 16:15	3521
Importance of Rock hive/Tafoni structure as geotourism point of view at Harihareshwar beach in Raigad district of Maharashtra, India	SHARAD GAJANANRAO PORATE	M211	2024-08-29 16:15	2024-08-29 16:30	3529

Title	Presenter	Venue	Start	End	Page
Wugongshan Geopark: A natural museum to study the granite dome and associated geological landforms	QINGCHENG HE	M211	2024-08-29 16:30	2024-08-29 16:45	3535
Study on Features and the Formation Mechanism of the Geomorphic Landscape of Slit-typed Danxia Gorge in the Loess Plateau in China	Hua DING	M211	2024-08-29 16:45	2024-08-29 17:00	3537
Karstological planning and construction control of new motorways and railway line crossing Classical Karst (Slovenia)	Martin Knez	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3539
STATE AND DEVELOPMENT OF GEOPARKS IN THE REPUBLIC OF UZBEKISTAN	Jurabek AZIMOV	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3540
Geoheritages of Georgia (The Caucasus) and potential for aspiring UNESCO Geoparks	Avtandil OKROSTSVARIDZE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3541
Establishing a Geoheritage Museum in Nanchang, China: A Nexus for Scientific Research, Educational Outreach, Artistic Display, and Touristic Interaction – A Case Study	Guanghua Liu	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3543
Middle Jurassic Chaukhi Gabbro-Diabase-Pillow lava massif: An Impressive Geoheritage of the Greater Caucasus, Georgia	Salome GOGOLADZE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3545
Geotourism Sites of the Outer Ukrainian Carpathians	Ihor BUBNIAK (BUBNYAK)	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3547
The Spatial-temporal evolution and determinants of homestays in the Dabie old-revolutionary-base-region, China.	Qiankun LIU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3549
Tourism Intelligence in Cabo Ortegal Geopark. Case of San Andrés de Teixido (Spain)	Sergio MUINO FREIRE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3550
Geological Characterization of the Geoparks within the Central Zone of the Limpopo Mobile Belt: Implication to the development of E - virtual geo-tourism, South Africa	Humbulani MUNDALAMO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	3551
S8 The Second 100 IUGS Geological Heritage Sites		Session Chair: Scientific Program Committee			
IUGS GEOLOGICAL HERITAGE SITES		C205	2024-08-27 14:00	2024-08-27 14:15	3567
Italian sites for the history of geosciences: Vesuvius and Agno Valley	Catherine (Kathleen) HISTON	C205	2024-08-27 14:30	2024-08-27 14:40	3564
Jurassic Coast: Lyme Regis	David A.T. HARPER	C205	2024-08-27 14:40	2024-08-27 15:00	3560
The Durbuy Anticline: a top geoheritage site in the UNESCO Global Geopark Famenne-Ardenne, Belgium		C205	2024-08-27 14:50	2024-08-27 15:15	3578
The combined Esmark Moraine and Otto Tank's Moraine (Norway)	Ezio VACCARI	C205	2024-08-27 15:00	2024-08-27 15:30	3561
Mesoproterozoic Belt-Purcell Supergroup	Kylie CAESAR	C205	2024-08-27 15:10	2024-08-27 15:45	3562
Iconic Colorful Navajo Sandstone of The Wave at Coyote Buttes, Vermilion Cliffs National Monument, Arizona, United States	Marjorie A CHAN	C205	2024-08-27 15:20	2024-08-27 16:00	3570
Molassic sediments and pinacles of Meteora, Greece	Nikolaos ZOUROS	C205	2024-08-27 15:30	2024-08-27 16:15	3569
Kikaijima Island – the history of coral reefs over 100,000 years	Atsuko YAMAZAKI	C205	2024-08-27 15:40	2024-08-27 16:30	3571
Wuda Plant Fossil Site: Permian Vegetational Lagerstätte unveiling ancient coal forming plants and forest		C205	2024-08-27 15:50	2024-08-27 16:00	3579
Middle Jurassic dinosaur footprints from the Serras de Aire and Candeeiros	Luis LOPES	C205	2024-08-27 16:00	2024-08-27 16:10	3572
A Dinosaur Quarry, the World's Wonder: The Dashanpu Middle Jurassic Dinosaur Fossils Site	Yi LI	C205	2024-08-27 16:10	2024-08-27 16:20	3573
Las Hoyas fossil site (Cuenca, Spain): an extraordinary Early Cretaceous faunal and floral wetland	Angela D. D. BUSCALIONI	C205	2024-08-27 16:20	2024-08-27 16:30	3556
The geoheritage and geodiversity framework of the newly listed Second 100 IUGS Geological Heritage Site, the Pleistocene Al Wahba dry maar of Saudi Arabia within the Kishb monogenetic volcanic field	Karoly NEMETH	C205	2024-08-27 16:40	2024-08-27 16:50	3552
Paricutin: The Volcano born in a Mexican cornfield	Lucero	C205	2024-08-27 16:50	2024-08-27 17:00	3558
HEISEI SHINZAN LAVA DOME / THE SECOND 100 IUGS GEOLOGICAL HERITAGE SITES	Setsuya NAKADA	C205	2024-08-27 17:00	2024-08-27 17:10	3554
Mackenzie Delta - coastal landforms created by giant sediment deposition of the fluvial system under Arctic permafrost conditions	Zbigniew Zwoliński	C205	2024-08-27 17:10	2024-08-27 17:20	3575
Outstanding geoheritage values of the Korean Getbol	Kyung-Sik WOO	C205	2024-08-27 17:20	2024-08-27 17:30	3559
Wakulla Spring, Florida, USA: A preeminent example of karst hydrogeology	Jonathan ARTHUR	C205	2024-08-27 17:30	2024-08-27 17:40	3565
Tepuis and quartzite karst of Gran Sabana, Venezuela		C205	2024-08-27 17:40	2024-08-27 17:50	3580
Vatnajökull - a complex interplay of rift, fire and ice	Zbigniew Zoliński	C205	2024-08-27 17:50	2024-08-27 18:00	3576
Inverted landscape of a Plio–Pleistocene phreatomagmatic monogenetic volcanic field: Tapolca Basin, Hungary	Karoly NEMETH	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3581
S9 Global Geopark Network (GGN)/Geoparks and Society		Session Chair: Asier Hilario, Min HUH			
[Keynote] Global Geoparks Network: 20th anniversary Protecting and managing Earth heritage - Building Sustainable Communities	Nikolaos ZOUROS	M211	2024-08-28 08:00	2024-08-28 08:15	3587
Suggestion of New Paradigm for UNESCO Global Geoparks	Daekyo CHEONG	M211	2024-08-28 08:15	2024-08-28 08:30	3583
The contribution of UNESCO Global Geoparks and Global Geoparks Network to Geosciences	Maria-Luise FREY	M211	2024-08-28 08:30	2024-08-28 08:45	3584
Samcheok Geopark: Promising and aspiring geopark in Korea	Kyung-Sik WOO	M211	2024-08-28 08:45	2024-08-28 09:00	3586
UNESCO Global Geoparks in Belgium - added value and perspectives.	Xavier DEVLEESCHOUWER	M211	2024-08-28 09:00	2024-08-28 09:15	3589

Title	Presenter	Venue	Start	End	Page
UNESCO's Earth Sciences Activities in Africa: Impacts on sustainable development and capacity building	Kombada Mhopjeni	M211	2024-08-28 09:15	2024-08-28 09:30	3591
Participatory inventory of geosites as a tool for geoheritage management in the Mixteca Alta UNESCO Global Geopark (Mexico)	Jose Luis SANCHEZ-CORTEZ	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3593
The Pollino UNESCO Global Geopark (southern Italy): a route in the Ancient Tethys Ocean	Giovanni MONGELLI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3595
Geopoetics as a new tool for the enhancement of the management of Natural and Cultural Heritage in UNESCO Global Geoparks	Artur SÁ	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3597
Geoheritage conservation and promotion on a small tropical island: first steps toward a UNESCO Geopark in Guadeloupe, Lesser Antilles	Yves MAZABRAUD	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3598
University and Geopark: Fundamental Partnership for the Preservation and Promotion of Geological and Cultural Heritage.	Stela MORAIS	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3599
Strategic Management of Geoparks: Conservation, Development, and Challenges.	Stela MORAIS	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3601
Identifying the Relationship Between Geoparks and Local Government Policies	기업 김	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3603
Geoheritage and Geodiversity in Yazd Province, the Potentials to Develop Shirkouh and Bahabad Geoparks, Iran	Alireza AMRIKAZEMI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3604
S10 TRANSNATIONAL UNESCO GLOBAL GEOPARKS: The need and historical value of designating a transnational UNESCO Geopark in East Asia - focusing on Mount Baekdu and the Hantan River on the Korean Peninsula		Session Chair: Scientific Program Committee			
[Keynote] Transnational UNESCO Global Geoparks	Patrick James MCKEEVER	M216	2024-08-26 16:00	2024-08-26 16:15	3608
[Invited] The master plan of Hantangang transnational UNESCO Global Geopark between ROK and DPRK.	KIL YOUNGWOO	M216	2024-08-26 16:15	2024-08-26 16:30	3606
Historical and cultural value of Mount Baekdu as seen through old Korean maps	Sangmyeoung MOON	M216	2024-08-26 16:30	2024-08-26 16:45	3607
Expected Effects and Key Strategic Approaches for Promoting a Transnational UNESCO Global Geopark Network in Northeast Asia, Including Baekdusan aUGGp and Hantangang UGGp.	Soo Jae LEE	M216	2024-08-26 16:45	2024-08-26 17:00	3609
The Designation and Denomination of Transnational Geoparks: A Case Study in East Asia	Jisung KIM	M216	2024-08-26 17:00	2024-08-26 17:15	3611
Necessity of Transnational UNESCO Global Geopark in East Asia: Focusing on Baekdu Mountain Geopark and Gangwon Peace Geopark	Donwon CHOI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3613
S11 General Topics		Session Chair: Scientific Program Committee			
Magnetic susceptibility measurement using simulated rock samples and application to the stone used in Himeji Castle, a World heritage site	Ayaha EMURA	M211	2024-08-26 16:00	2024-08-26 16:15	3615
Inventory and Revision of Paleobiodiversity in the Uberaba Geopark: Challenges and Perspectives	Isadora	M211	2024-08-26 16:15	2024-08-26 16:30	3618
The Journey: IUGS Geological Heritage Sites of Namibia	Helke Brigitte MOCKE	M211	2024-08-26 16:30	2024-08-26 16:45	3616
Study on Environmental Characteristics of the Eundae-ri water spider(Argyroneta aquatica) habitat in Hantangang River Global Geopark	Jinah MOON	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3619
CoalHeritage project: Unlocking the potential of Europe's coal mining heritage	Nicolas CHARLES	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3620
The Italian Geosite Inventory: a useful tool for knowledge and geoconservation.	Elisa Brustia	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3622
Illuminating the cultural traces in the transition zones: Examples from the Mediterranean region	Nikos PAPADOPOULOS	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3623
T28 Forensic Geology and Medical Geology					
S2+S1+S3 Medical Geology in Honour of Professor Olle Selinus (Special Session)		Session Chair: Scientific Program Committee			
Olle Selinus (1943-2023): The Founder of Modern Medical Geology	Anna LADENBERGER	C205	2024-08-26 16:00	2024-08-26 16:15	3660
Comprehensive assessment and multivariate statistical analysis of Transfer Factors soil-to-plante stimated from bioavailable concentrations: A Case Study in the Campania Region, Southern Italy	Lucia Rita PACIFICO	C205	2024-08-26 16:15	2024-08-26 16:30	3642
Investigating the relationship between health and the environment using soil and air pollution data in a changing climate.	Jennifer M MCKINLEY	C205	2024-08-26 16:30	2024-08-26 16:45	3641
Coupling of neurodegenerative diseases to element distribution through geospatial statistics	Sarah CONRAD	C205	2024-08-26 16:45	2024-08-26 17:00	3646
Anthropogenic gadolinium in surface and groundwaters of Poland	Irena Agnieszka WYSOCKA	C205	2024-08-26 17:00	2024-08-26 17:15	3658
Role of Critical Minerals in Medical Geology: Applications and Implications	PRATIK PRAVIN GODBOLE	C205	2024-08-26 17:15	2024-08-26 17:30	3652

Title	Presenter	Venue	Start	End	Page
"RASASHASTRA": AN ANCINET INDIAN MEDICINAL SYSTEM PROMOTING MEDICAL GEOLOGY	Kirtikumar Ramkrushna RANDIVE	C205	2024-08-26 17:30	2024-08-26 17:45	3659
Forensic application of traceability technology in illegal marine sand mining crimes	Ping YIN	C205	2024-08-26 17:45	2024-08-26 18:00	3656
The Potential Traceability of Mineral Commodities using Artificial Taggant Particles	Laurance John DONNELLY	M217	2024-08-26 16:15	2024-08-26 16:30	3638
Determining the geographic origin of illegally imported Chinese dinosaur nests retrieved in Australia	Robert William FITZPATRICK	M217	2024-08-26 16:30	2024-08-26 16:45	3649
Exploration of Characteristics of Pollen Assemblages in Soil Sampes of China	ping wang	M217	2024-08-26 16:45	2024-08-26 17:00	3625
Mineralogy and morphology of earth materials in vehicle wheel-rims as significant trace evidence in a double murder and arson investigation in Australia	Robert William FITZPATRICK	M217	2024-08-26 17:00	2024-08-26 17:15	3654
Hazard and exposure assessment in contaminated land investigations and environmental management: The Lavrion case study, Hellenic Republic	ALECOS DEMETRIADES	M217	2024-08-26 17:30	2024-08-26 17:45	3639
The Development of Strontium and Oxygen Isoscapes to Determine a Geographical Origin of Human Remains in Korea	Seongshin GWAK	M217	2024-08-26 17:45	2024-08-27 16:00	3644
[Keynote] Community to Combat Crisis: Steps to engage with our environment and progress to better human and environmental health outcomes.	Kim DOWLING	M215	2024-08-27 16:00	2024-08-27 16:15	3645
Occurrence, Sources, Mechanisms of Enrichment and Possible Human Health Impacts of Fluoride-Bearing Groundwater in the Central Parts of the White Volta River Basin of Ghana	Moses Boakye OKYERE	M215	2024-08-27 16:15	2024-08-27 16:30	3626
Assessment of potentially harmful elements on human health and agriculture of surface and groundwater sourced from the granito-gneissic phreatic aquiferous formations in Bertoua and its environs, east region Cameroon.	SHARON NTUBE NGWESE	M215	2024-08-27 16:30	2024-08-27 16:45	3628
Environmental and Health Risk Assessment of Coal Mining in Moatize, Tete, Mozambique	Micaela Arlete Jose CHAPO COSSA	M215	2024-08-27 16:45	2024-08-27 17:00	3630
The occurrence of potentially harmful elements in gold mine tailings and their possible impacts on the environment and public health with reference to the Welkom goldfields in South Africa - A review	Rinae MAKHADI	M215	2024-08-27 17:00	2024-08-27 17:15	3632
Geochemical and isotropic composition assessment of groundwater consumed by a vulnerable population with chronic kidney disease of unknown origin (CKDu) in the dry zone of Sri Lanka	Navodya Dhananjalee MAHALEKAM	M215	2024-08-27 17:15	2024-08-27 17:30	3636
Potential risk of CO poisoning for casual workers exposed to emissions from clamp kiln: a South African perspective.	Lawrence DIKO MAKIA	M215	2024-08-27 17:30	2024-08-27 17:45	3648
Dimensionality reduction for visualizing gold trace element geochemistry through the chain of production in Brazil using UMAP	Angel VERBEL	M215	2024-08-27 17:45	2024-08-27 18:00	3657
Identification of mercury in stream sediment in Yanomami Indigenous Land, Roraima, Brazil	Patricia DURINGER Jacques	M215	2024-08-27 18:00	2024-08-27 18:15	3634
"We Did not Notice This Demon in Our Backyard!"—Introducing a New Source of Geogenic Health Hazard	Kirtikumar Ramkrushna RANDIVE	M215	2024-08-27 18:15	2024-08-27 18:30	3651
Mineralogical and elemental information for soil geolocation tracing	hongling guo	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3661
Forensic Geology in Chile: Foundations of a scientific basis for Justice and Environmental Sciences.	Kristian AGURTO VELASQUEZ	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3662
The impact of ashes produced during a fire event on the soil: a comparative study between anthropogenic and natural sources in the Campania region (Southern Italy).	Lucia Rita PACIFICO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3664
A Study on Discrimination Capability of Soil for Forensic Comparison based on Statistical Approach in South Korea	Yu Ran LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3666
Tracing the geographical origin of bottled water collected in South Korea via isotopic and elemental analyses	Byeong-Yeol SONG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3667
Medical and environmental aspects of multipurpose geochemical mapping	Iosif VOLFSON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3668
Occurrences of potentially toxic elements such as uranium (U) and molybdenum (Mo) in the Karoo ground-and-surface waters near Beaufort West, Western Cape, South Africa: a possible health threat to the local population?	Okuhle POTO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3670
New insights into the geological occurrence, morphology and toxicology of New Zealand erionite minerals	Martin Brook	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3671
WATER QUALITY FOR HUMAN CONSUMPTION IN THE CONTEXT OF ABANDONED ARTISANAL GOLD MINING	Marina THIMOTHEO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3672
T29 Engineering Geology and Geomechanics					
S2+1 General Topics		Session Chair: Scientific Program Committee			
Crack Propagation Analysis Through Digital Image Correlation in Volcanic and Plutonic Specimens Under Brazilian Tensile Tests	Chamran KAZEMI	C109	2024-08-30 08:00	2024-08-30 08:15	3678

Title	Presenter	Venue	Start	End	Page
Effects of heating-LN2 cooling on the Brazilian tensile strength of rock materials	BIKASH KUMAR KUMAR RAM	C109	2024-08-30 08:15	2024-08-30 08:30	3684
Influence of anthropogenic factors on landslide activity in the Moskva river valley (Moscow, Russia)	Pavel Novikov	C109	2024-08-30 08:30	2024-08-30 08:45	3682
The Engineering Geology of Havant Thicket Reservoir – The first to be built in the United Kingdom in over three decades	Hollie Elizabeth FISHER	C109	2024-08-30 08:45	2024-08-30 09:00	3677
The engineering geology of London's raised reservoirs with a summary of ground investigation risks and recommendations, citing techniques used at three sites	Hollie Elizabeth FISHER	C109	2024-08-30 09:00	2024-08-30 09:15	3676
Damage Evolution Mechanisms of Granite Rock under Cyclic Loading: X-Ray Computed Tomography and Digital Volume Correlation Technique Analysis	Shangtong YANG	C109	2024-08-30 09:15	2024-08-30 09:30	3688
INTERPLAY OF COHESIVE-ORGANIC SOILS AND DISPERSIVE BEHAVIOR: SHAH ALAM'S SUSCEPTIBILITY TO WATER PONDING	NOR SHAHIDAH MOHD NAZER	C109	2024-08-30 09:30	2024-08-30 09:45	3687
Engineering-geological characteristics of pyroclastic deposits from paroxysmal eruption of Shiveluch volcano in 2023 (Kamchatka Peninsula)	Mariya NIKULINA	C109	2024-08-30 09:45	2024-08-30 10:00	3680
Shear behavior and deformation mechanisms of reactivated ancient landslides soil in the Nepal Himalaya	Bharat Prasad BHANDARI	C109	2024-08-30 10:00	2024-08-30 10:15	3679
Frequency dependence of internal mechanical losses in rocks in the low-frequency range	Aleksandr Sergeevich VOZNESENSKII	C109	2024-08-30 10:15	2024-08-30 10:30	3674
Sensibility analysis of the parameters "Factor of Safety" and "Probability of Failure" in Slope Stability	Rubén Eduardo ROMERO MAYMA	C109	2024-08-30 10:30	2024-08-30 10:45	3686
Comprehensive studies of the engineering geological behavior of red clay soils in Bangladesh	Md Shohel RANA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3689
Successful Replacement for Slope Stability Enhancement in Group-housing Site	BYUNG DON RO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3691
Paleostress from healed microcracks and fluid inclusions in granites in the northeastern and southwestern areas of the Ogcheon folded belt, South Korea	Seong-Seung KANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3692
Comparative analysis of slope stability assessment using LightGBM and CatBoost	Seong-Seung KANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3693
A comparative study of cation exchanges in 'extreme types of clay minerals' to modify the swelling index of the foundation soil underlying the civil engineering structures	Sudipta SARKAR	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3695
Rockslides and Rock Avalanches in the Upper Part of Mzymta River Valley (Caucasus, Russia)	Oleg ZERKAL	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3697
A Basic Study on the Development of Trenchless Excavation Technology and Construction Method	YONG BAEK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3699
Investigating physico-chemical and mechanical properties of Cretaceous sandstones within Khorat Cuesta, Northeastern, Thailand	Prachya Tepnarong	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3700
Evaluation of operating cost and economic feasibility of a limestone open pit mine in Korea	Dong-Kil LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3701
Case of Rockmass Classification in the Submarine Ground Where Marine Investigation is Difficult Due to Rapid Current	Seong-Woo MOON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3702
Experimental study on mechanical properties of pore-filling and fracture-filling clayey silt hydrate-bearing sediments	Yiming LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3703
Engineering geological studies and expected support design during the construction of diversion tunnels, Renukaji Dam Project, District Sirmaur, Himachal Pradesh, India	TRIPTI BABA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3704
Review on geological and engineering aspects of gypsum solubility and dissolution in the Arabian Gulf coast	Sungbin YIM	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3706
T30 Urban Geology					
S2+S1 General Topics		Session Chair: Scientific Program Committee			
Mainstreaming urban geoheritage as a tool for environmental education and geotourism in local administrations	Juana VEGAS	M212	2024-08-30 08:00	2024-08-30 08:15	3708
The monitoring of land subsidence and groundwater level in the southeast Kanto groundwater basin, Japan	Atsushi KAGAWA	M212	2024-08-30 08:15	2024-08-30 08:30	3709
Characterizing Groundwater Drought-Induced Land Subsidence Dynamics in Economic Hub of State of Gujarat, India	Anuradha Karunakalage	M212	2024-08-30 08:30	2024-08-30 08:45	3710
Bridging the Data Gap with 3D Geoscientific City Models (GeoCIM): A case study of the Liberec municipality, Czech Republic	Jan JELENEK	M212	2024-08-30 08:45	2024-08-30 09:00	3711
Locations that are prone to liquefy and locations that are difficult to liquefy by strong earthquakes in the Tokyo bay reclaimed land: Knowledge for urban planning that is unlikely to cause earthquake damage	Osamu KAZAOKA	M212	2024-08-30 09:00	2024-08-30 09:15	3713
[Keynote] Safe Urbanization in an Alluvial Terrain (Bangladesh): In the Reality of Seismic Risk and Climate Change	A K M Khorshed ALAM	M212	2024-08-30 09:15	2024-08-30 09:30	3715
Assessment of tunnel stability in active fault zone: Integrating A multidisciplinary approach	Kiwoong PARK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3717

Title	Presenter	Venue	Start	End	Page
T31 Geohazards					
S1+S4 Surface faulting and near-fault earthquake hazard		Session Chair: Paolo BONCIO			
[Keynote] Near-fault earthquake multi-hazards	Timothy Austin STAHL	M312	2024-08-28 09:30	2024-08-28 09:45	3719
Updating empirical regressions for Probabilistic Fault Displacement Hazard Analysis of distributed ruptures for dip-slip faults	Paolo BONCIO	M312	2024-08-28 09:45	2024-08-28 10:00	3726
Paleoseismology and capable faults in the Rieti intermountain basin (Central Italy)	Alessandro Maria Michetti	M312	2024-08-28 10:00	2024-08-28 10:15	3724
The role of brittle rock mass fracturing in alpine slope instabilities	Reinhard GERSTNER	M312	2024-08-28 10:15	2024-08-28 10:30	3722
Analysing the dynamics of rockfall at Koto Panjang, Indonesia : A Multi-Temporal Approach Through Street View Images and UAV	Tiggi Choanji	M312	2024-08-28 10:30	2024-08-28 10:45	3721
Landslide susceptibility assessment based on multi-sources data in the Three Gorges Project reservoir area	Ningtao WANG	M312	2024-08-28 10:45	2024-08-28 11:00	3720
August 2022 monsoon thunderstorm impact on the sedimentation in a tectonically active small catchment; case study of Saydoon dam reservoir, Southern Iran	Arash Barjasteh	M312	2024-08-28 11:00	2024-08-28 11:15	3718
Evaluating the Relationship between Catchment Area Capacity and Constructed Slope Failure Probability in South Korea	alain bindu	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3727
Suggestions for safety distance based on surface rupture characteristics and its importance to active fault Investigations	Yeoeun SEO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3729
The advantages of using a combination of ground, air, and space technologies for mitigating large landslides in Uzbekistan.	Abdulla Baratov	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3730
Generating plausible multifault ruptures with empirical rupture simulation	Timothy STAHL	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3731
Geo-engineering characteristics and performance analysis of the landslide mitigation measures implemented in the Rohingya camps in Bangladesh	Farhad HOSSAIN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3732
Probabilistic Fault Displacement Hazard Analysis of a strategic dam in the Sansepolcro graben (Northern Apennines, Italy): methodologic implications for distributed faulting	Paolo BONCIO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3734
Landslide Prediction in Nepal Himalaya with a National-Scale Rainfall-Triggered Nowcast System	Ananta Man Singh Pradhan	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3736
Analysis of Landslide Hazard and Geoenvironmental Condition in Rangamati and adjoining areas of Chittagong-Rangamati National Highway Road, the South-Eastern Hilly Districts of Bangladesh	Lubna KHONDAKAR	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3737
InSAR techniques and multi-risk assessment approach for monitoring Cultural heritage	Daniele SPIZZICHINO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3739
Chronological constraints of a fault scarp in a glaciated high mountain environment: the Coronas fault scarp	MARÍA ORTUÑO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3741
Landslide Hazards and Forecast under Changing Climatic Patterns	Devesh WALIA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3742
S2 Outreach tools as a way to increase preparedness for geological hazards		Session Chair: María ORTUÑO, Jin-Hyuck CHOI			
[Keynote] Geological risk assessment in Mexico City: The Interactive Observatory of Land Subsidence and Fracturing, OIHFRA	Dora Celia CARREON-FREYRE	M312	2024-08-28 08:00	2024-08-28 08:15	3745
[Keynote] The UNESCO Land Subsidence International Initiative (LaSII)	Dora Celia CARREON-FREYRE	M312	2024-08-28 08:15	2024-08-28 08:30	3747
Citizen science in response to the climate crisis : focus on old building retrofit for low-income people	Jong-Won Lee	M312	2024-08-28 08:30	2024-08-28 08:45	3743
Current Research and Education Efforts for Proactive Landslide Disaster Management in the Context of Climate Change in Korea	Joon-Young PARK	M312	2024-08-28 08:45	2024-08-28 09:00	3744
Experience and challenges of popularizing sciences related to earthquake disasters in S. Korea	Jin-Hyuck CHOI	M312	2024-08-28 09:00	2024-08-28 09:15	3749
Presenting the Outcome of Earthquake Prediction Spatial Probability Mapping Utilizing Explainable Artificial Intelligence in the Nepal Himalayas	Suchita SHRESTHA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3750
SINKHOLES AND UNDERGROUND WATER FLOW AS A RESULT OF PROLONGED RAINFAL; THE CASE OF SAKATA, CHOWE, AND ZOMBA IN SOUTHERN MALAWI	Joseph CHIRWA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3751
S3 Geohazards: A global phenomenon and their Reduction Strategies		Session Chair: Madumita DAS			
The Kumalu catchment area, Bulolo District, Morobe Province, Papua New Guinea: Some findings and conclusions about the floods and landslides since 1950s	Shekinah Pilamp	M312	2024-08-27 08:00	2024-08-27 08:15	3761
Geological Survey Ireland, managing geohazards in a safe country, landslides, groundwater flooding and coastal change.	Koen M VERBRUGGEN	M312	2024-08-27 08:15	2024-08-27 08:30	3763
Development of Classification and Grading Approach for Potential Large-scale Landslides and its Application	TING-YU WU	M312	2024-08-27 08:30	2024-08-27 08:45	3765
Assessing the influence of geological structures and lineaments on the landslides in KwaZulu-Natal Province, South Africa: A case study on the Sangwana Mountain landslide	MAWANDE NCUME	M312	2024-08-27 08:45	2024-08-27 09:00	3766
Characters of Landslides Development in Arid Areas, Assessment and Trends	Gany BIMURZAEV	M312	2024-08-27 09:00	2024-08-27 09:15	3759

Title	Presenter	Venue	Start	End	Page
Man-Induced Landslides in Uzbekistan: Overview and Case Studies	Gany BIMURZAEV	M312	2024-08-27 09:15	2024-08-27 09:30	3757
Geohazards and Risk Reduction Framework in India	VINOD KUMAR SHARMA	M312	2024-08-27 09:30	2024-08-27 09:45	3755
Recent landslides of liquefaction in Uzbekistan triggered by resonant frequency oscillations during deep strong Pamir-Hindu Kush earthquakes	Mansurjon Makhmudjanovich TASHPULATOV	M312	2024-08-27 09:45	2024-08-27 10:00	3753
Geological characteristics of the area where land subsidence has continued for more than 12 years with in liquified-fluidized part on the Tokyo bay reclaimed land at the 2011 off the Pacific Coast of Tohoku Earthquake	Osamu KAZAOKA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3768
S5 Our Tasks on Global Submarine Geohazard Issues to our future earth		Session Chair: Kiichiro KAWAMURA			
Tectonic structure and deformation along the Manila Trench subduction zone: Implications on submarine geohazards in the South China Sea eastern margin	Leo ARMADA	M312	2024-08-27 14:30	2024-08-27 14:45	3779
Imaging offshore deformation features in western Luzon using integrated geophysical analyses	Carla Besa DIMALANTA	M312	2024-08-27 14:45	2024-08-27 15:00	3777
Spatial time series variation of contourite drifts on active margins: Examples from the Kuril Trench in the NW Pacific	Hisashi IKEDA	M312	2024-08-27 15:15	2024-08-27 15:30	3773
In-situ Observation and Machine Learning Prediction of Marine Shallow Gas Emission	Cong HU	M312	2024-08-27 16:45	2024-08-27 17:00	3780
Key Technologies and Equipment of Geological Environment Observation in Deep-Sea Development	Yonggang Jia	M312	2024-08-27 17:00	2024-08-27 17:15	3772
How do overpressure-driven hydrofractures grow in sedimentary basins?	Qing WANG	M312	2024-08-27 17:15	2024-08-27 17:30	3770
Submarine geohazards and renewable energy	Kiichiro KAWAMURA	M312	2024-08-27 17:30	2024-08-27 18:00	3771
Depositional process of contourite on active margins: Examples from the Kuril Trench and the Japan Trench in the NW Pacific		M312	2024-08-27 15:00	2024-08-27 15:15	3775
In-Situ Observation on the Interaction of Deep-Sea Internal Solitary Waves with the Seabed		M312	2024-08-27 15:30	2024-08-27 15:45	3781
Submarine geohazards and educational materials	Kiichiro KAWAMURA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3783
An optimal geological method to decipher active faults and related lineaments at Yamaguchi, SW Japan	Momoko TSUTSUMI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3785
Microplastics: diffusion into ocean floors by tsunamis and typhoons and application for age determination	Kiichiro KAWAMURA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3787
A harmonized database on geological events occurrence as a tool to support geohazard assessment in European seas	Andrea FIORENTINO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3788
Possible development and implication of subsurface fault structures offshore northeast Taiwan	Chien-Wei HSU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3790
Active Fault and fold structures in northern Taiwan Strait	YI-PING CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3791
S6+S7 Advances in Modeling and Simulation of Geological Disaster Problems		Session Chair: Yu Huang			
[Keynote] Rheological behaviour of pressure-controlled steady slope flow with coexistence of multiple flow regimes	Chongqiang ZHU	M312	2024-08-26 16:00	2024-08-26 16:15	3798
Shallow Subsurface 3D Velocity Structure Identification in Turkey Antakya based on Microtremor Horizontal-to-Vertical Spectral Ratio	Jikai SUN	M312	2024-08-26 16:15	2024-08-26 16:30	3792
Framework for prioritization strategies for slope reinforcements under heavy rainfall based on probabilistic connectivity of road networks	Zhengying he	M312	2024-08-26 16:30	2024-08-26 16:45	3793
Energy evolution of subaqueous gravity flows composed of viscous liquids and particles	Chen PENG	M312	2024-08-26 16:45	2024-08-26 17:00	3794
DEM modeling of undrained cyclic triaxial behavior in submarine loose sediments under wave loading: the influence of fine contents	Yandong Bi	M312	2024-08-26 17:00	2024-08-26 17:15	3795
Simulating Cyclic Injection-Induced Fatigue in Rocks	Chang Xia	M312	2024-08-26 17:15	2024-08-26 17:30	3800
Prediction of landslide hazard using LS-RAPID model. A case study in Tia Dinh area (Dien Bien province, Vietnam)	Ha Duc NGUYEN	M312	2024-08-26 17:30	2024-08-26 17:45	3796
Numerical Insights into Microbially Induced Desaturation (MID) in Layered Silts and Sands	Patrick Kwon	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3801
Karst geohazard and climate change: case of Lithuania	Jonas SATKUNAS	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3802
From Hazard to Opportunity: Success Story of Biogenic Gas Exploration in North Sumatera Basin through Heating Rate Analysis in Offshore Area	Anggit KURNIA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3803
Improving landslide susceptibility assessment using probabilistic back analysis and Markov Chain Monte Carlo simulation	Hyuck-Jin PARK	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3804
Seismic Imaging of Fault Structures Offshore Northern Taiwan Mountain Belt	Ching-Yun HUANG	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3805
Appraisal of the present-day geodynamics in Andaman Islands through campaign mode GNSS survey	SNEHASIS BHATTACHARYA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3806
Smart Monitoring System for Flexible Barrier Using Accelerometer and Corrosion Sensors	JunHa BAEK	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3808

Title	Presenter	Venue	Start	End	Page
Stability Assessment of the Rock-Cut Slopes Based on a Multi-Method Approach	PRATEEK SHARMA	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3810
INVESTIGATION OF THE RELATIONSHIP BETWEEN GEODYNAMIC AND GAS DYNAMIC PROCESS IN MINING AREAS	Alexander KOBYLKIN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3811
GEOMORPHOLOGICAL EVOLUTION AND ASSOCIATED RISK ON THE SLOPES OF CERRO SOLO AND TECHADO NEGRO, TORRE GLACIER VALLEY, SANTA CRUZ PROVINCE, ARGENTINA	Daniela SCHMIDT	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3812
SUSCEPTIBILITY TO LANDSLIDES IN AN AREA OF 48 KM2 IN THE SURROUNDINGS OF BIOTOPO MARIO DARY RIVERA NATURE RESERVE, PURULHÁ, BAJA VERAPAZ, GUATEMALA	Gabriel MORALES RECINOS	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3814
Study on coastal flooding from Probable Maximum Storm Surge(PMSS) by the changes in Probable Maximum Typhoon Intensity at the nuclear power plant site	JAEWOONG RYU	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3813
Estimation of debris flow damage areas using influencing factors and empirical formula	Jaeho LEE	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3815
T32 Mitigation and Adaptation in the Climate Crisis					
S1+S2 Geoscience Contributions to Climate Change Mitigation Strategies		Session Chair: Scientific Program Committee			
Soil CO2 change and rainfall effect in growing season in a karst grassland of Slovenia	Cheng ZHANG	C106	2024-08-30 08:00	2024-08-30 08:15	3824
Integrated assessment of gully erosion susceptibility for risk informed urban planning: A case study of Rundu, Namibia	Giesberta Naipopya Shaanika	C106	2024-08-30 08:15	2024-08-30 08:30	3821
Carbon Capture, Utilisation, and Storage opportunities in South Africa's highest carbon dioxide emissions hub: opportunities for the Just Transition	Taufeeq DHANSAY	C106	2024-08-30 08:30	2024-08-30 08:45	3823
Solid Carbon: Safe, durable and scalable geological carbon storage in the ocean crust	Martin SCHERWATH	C106	2024-08-30 08:45	2024-08-30 09:00	3817
Impact of Climate Change and Rapid Urbanization: A need for Climate Resilience Plans- based on Flash Flood Analysis in Hyderabad Metropolitan area through a Geospatial approach	Anoop V M	C106	2024-08-30 09:00	2024-08-30 09:15	3819
Evaluation of energy saving effects in university campus rooftop greening through the use of high concentrations of carbon dioxide in lecture rooms	Jeongwoo PARK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3826
Artisanal Biochar Production: A Sustainable Pathway for Climate Resilience in Rwanda	Magalie NTAHOKAJA	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3828
Application of Petrography to the Assessment of Philippine Coastal Concrete Structures Exposed to Extreme Weather Conditions	Chelly Mei Nacional TANPOCO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3829
Investigation of hydrochemical and stable carbon isotope compositions as effective tracers for tracing CO2 leakage: lessons from two controlled CO2 release tests	Hyunkwon Do	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3831
Enhanced basalt weathering for CO2 sequestration under wheat-corn rotation pattern in Xuyi County, China	Yijaing XU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3833
S3+S4 Offshore Monitoring Technology and its Application for CO2 Storage		Session Chair: Scientific Program Committee			
[Keynote] Building on Bedrock: Geosciences' Role in Mitigation and Adaptation	Lisa GRAUMLICH	C106	2024-08-30 09:30	2024-08-30 09:45	3842
Non-repeatable Noise Attenuation on Time-lapse Prestack Data using Fully Convolutional Neural Network	Hanjoon Park	C106	2024-08-30 09:45	2024-08-30 10:00	3837
Artificial CO_2 release experiments for the development of stationary monitoring system in Korea	JONGHA HWANG	C106	2024-08-30 10:00	2024-08-30 10:15	3838
Numerical modeling of subsurface fluid injection using the poroelastic finite element code	Chan-Hee JANG	C106	2024-08-30 10:15	2024-08-30 10:30	3840
Research on a CO2 Internet of Things online monitoring system for marine carbon storage	JUNXI TU	C106	2024-08-30 10:30	2024-08-30 10:45	3835
Repeatability analysis of time-lapse OBC data for CCS in the offshore of Pohang, Korea	YONGHWAN JOO	C106	2024-08-30 10:45	2024-08-30 11:00	3841
Unraveling the Complex Nexus of Geology, Water Quality, and Forage Impact on Enteric Methane Emissions: A Case Study from North Kivu, Democratic Republic of the Congo	Tomple Byamungu Mayange	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3843
Feasibility study for subsurface imaging using onshore VSP geophone and DAS data	Hanjoon PARK	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3845
Numerical Modeling of Two-Way Coupled Simulation for Geological Carbon Storage	Hyun Chul YOON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3846
Reservoir simulation study for the injectivity and geomechanical stability in the Gunsan basin	Taehun LEE	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3847
Building an initial velocity for 3D OBC seismic data processing in the Gunsan basin, offshore western Korea	Woohyun SON	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	3848

Title	Presenter	Venue	Start	End	Page
T33 Big Data and Artificial Intelligence (AI) in Geoscience					
S1+S2 Application of AI algorithms in natural hazards modelling		Session Chair: Biswajeet PRADHAN, Saro LEE			
Development of a surrogate model to improve the efficiency of groundwater level fluctuation pattern-based hydrologic properties evaluation	JIHO JEONG	M217	2024-08-27 08:00	2024-08-27 08:15	3849
Machine-learning-based microearthquake detection for the southern Korean Peninsula	Byeongwoo Kim	M217	2024-08-27 08:15	2024-08-27 08:30	3850
Investigation of Important Factors on the Field-scale DNAPLs Contamination by Applying Polynomial Chaos Expansion and Random Forest	Taehoon Kim	M217	2024-08-27 08:30	2024-08-27 08:45	3851
Improvement of performance of in-situ virtual monitoring system of the occurrence probability for high concentrations of naturally occurring radioactive materials in groundwater through the solution of the data imbalance problem	Hyeongmok LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3853
Pollution Sources Identification and Sustainable Management Strategy of Groundwater in Volcanic Islands: A Case Study of Jeju Island Using an Integrated Multivariate Statistical and Machine Learning Approach	Hyuntai AHN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3854
Evaluation of the Feasibility of Applying Machine Learning Techniques for Landslide Prediction	Hyeyeon JEON	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3856
Convolutional LSTM networks for predicting spatio-temporal variability of standardized groundwater level index in South Korea	Sanghoon LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3857
Oil spill analysis around Small Island Developing States through multimodal large model	Xiaohui YU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3858
Prediction of groundwater levels of National Groundwater Monitoring Network in South Korea using LSTM (Long Short-Term Memory)	hyowon AN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3859
S3 Prediction of reservoir response using machine learning and data integration		Session Chair: Scientific Program Committee			
A deep learning-based proxy model for 3D channel reservoir characterization	Youjun LEE	M217	2024-08-27 14:30	2024-08-27 14:45	3860
Carbonate structures and reservoir identification based on machine learning methods: A case from the Lower Paleozoic of Jiyang Sub-Basin	Chenglong LIU	M217	2024-08-27 14:45	2024-08-27 15:00	3861
Intelligent logging identification of petrophysical facies	Xinhao ZHANG	M217	2024-08-27 15:00	2024-08-27 15:15	3863
Productivity Prediction of shale basins in the USA using machine learning and data integration	Sungil KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3864
Fracture identification based on graph convolutional network in continental shale oil reservoirs	Guoqing LU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3865
S4 Data-driven or AI-driven Discovery in Geosciences		Session Chair: Guoxiong CHEN			
Cascade Effects of Global Supply Chains Induced by Regional Conflicts Increase Global Inequality	Rongtian Zhao	M217	2024-08-27 16:00	2024-08-27 16:15	3866
Innovative input-output geographical cascading model for detection and simulation of induced negative shocks in global supply chains	Mo Zhang	M217	2024-08-27 16:15	2024-08-27 16:30	3867
Research on Petroleum Geological Reserve Prediction Based on Machine Learning	XIAOYU AN	M217	2024-08-27 16:30	2024-08-27 16:45	3868
Leveraging Machine Learning, Natural Language Processes and Knowledge Representations to Facilitate the Discovery of Insights and Analogues in Unstructured Geoscience Literature	Phoebe MCMELLON	M217	2024-08-27 16:45	2024-08-27 17:00	3871
An ensemble model for predicting mineral prospectivity: a case study in the Malipo W-Sn mineral district, Yunnan Province, China	Jie ZHAO	M217	2024-08-27 17:00	2024-08-27 17:15	3873
Drivers of Phanerozoic Marine Biodiversity: Insights from Machine Learning	Guoxiong Chen	M217	2024-08-27 17:15	2024-08-27 17:30	3875
Intelligent Identification of Target Properties of Downhole Rockfall Funnels in Pulang Copper Mine	JIANGUO CHEN	M217	2024-08-27 17:30	2024-08-27 17:45	3876
AusGeochem: Unveiling Earth through 4D Geochemistry	Halimulati ANANUER	M217	2024-08-27 17:45	2024-08-27 18:00	3878
Decoding Informative Factors for Large Earthquake Occurrence Recognition from the Earthquake Catalogs with Explainable Machine Learning	Jinsu JANG	M217	2024-08-27 18:00	2024-08-27 18:15	3880
Explainable machine learning to uncover hydrogen diffusion mechanism in clinopyroxene	Anzhou LI	M217	2024-08-27 18:15	2024-08-27 18:30	3881
Time-limited lithogeochemistry of marine and terrestrial alternation on the Tibetan Plateau	Xinwei Liu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3882
Calculation of crustal thickness and characterization of its spatial distribution in the South American Andes magmatic arcs	Kunyi WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3884
A data-driven approach for adaptive utilization of geothermal energy worldwide by examining top 100 geothermal cities	Wang XU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3886
Quantitative analysis of fluid inclusions characteristics based on data drive	Xia QINGLIN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3888
Comprehensive Evaluation of Tobacco-planting Soil Fertility Based on Machine Learning: A Case Study of Hezhou City, Guangxi	JUNXI TU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3869

Title	Presenter	Venue	Start	End	Page
Machine Learning and Magma Fertility Determination: Revealing Spatio-temporal Variation of the Favorability of Porphyry Copper Formation	Yuanzhi ZHOU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3890
The formation and evolutionary process of the North China Craton during early Precambrian: Implications from big data analysis	Zhenjie ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3891
Application of remote sensing to identify Copper–Lead–Zinc deposits in the Heiqia Area of the West Kunlun Mountains, China	yuhai FAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3892
Machine learning models for investigating the primary water content of pyroxene in mantle-derived magmas	Huan CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3893
Development of clustering model for XRD experimental data from the Ulleung Basin, Korea	Ju Young PARK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3894
A Method of Geological Mapping Based on Deep Learning	Fengdan LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3896
Data-driven Automated Detection and Characterization of Dinosaur Footprints	Yeoncheol HA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3898
Deep Learning 3D Mineral Segmentation with micro-CT and micro-XRF	Yiming WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3899
Multi-scale full waveform inversion based on a convolutional neural network	Hong LIU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3900
Improvement of YOLO Model for Borehole Breakout Detection Using Data Augmentation	Juyeol YEOM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3902
Mineral Identification and Mapping Algorithm Based on X-ray Fluorescence Spectroscopy and Self-supervised Strategy	Weiming JIANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3904
GIS Tool Learning with Large Language Model	Zhizhen YU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3905
Improvement and Evaluation of the RAG Application	Jiarui CAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3906
Predicting Methane Concentration in Chromitites: An Application of Ensemble Learning Algorithms in Chro-mitites from Greece	Elena IFANDI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	3907
S6 Big Data and Artificial Intelligence (AI) in Geomodeling		Session Chair: Scientific Program Committee			
Characterizing subsurface structures from hard and soft data with multiple-condition fusion neural network	Zhesi Cui	M217	2024-08-28 09:30	2024-08-28 09:45	3911
Forecast of Shale Lithofacies Types in the Dongying Fault-depressed Lacustrine Basin Based on Machine Learning	Zhengwei FANG	M217	2024-08-28 09:45	2024-08-28 10:00	3909
A new sedimentary facies geo-modeling method based on CGAN deep-learning algorithm	Yiming YAN	M217	2024-08-28 10:00	2024-08-28 10:15	3912
A method using convolutional interactive perception network for well logging data prediction.	Xin LUO	M217	2024-08-28 10:15	2024-08-28 10:30	3910
Deep learning-based multiscale digital rock modeling integrating 2D and 3D rock images	Peng Chi	M217	2024-08-28 10:30	2024-08-28 10:45	3908
Application of BPNN neural network algorithm driven by data and model in bitumen content prediction of Silurian Kepingage Formation reservoir in Tazhong area	Yanjun Lu	M217	2024-08-28 10:45	2024-08-28 11:00	3913
Predicting the lithofacies of Longdong lacustrine shale oil based on the intelligent fusion of multi-scale well logging data	Quansheng MIAO	M217	2024-08-28 11:00	2024-08-28 11:15	3914
Research on Knowledge Sharing of WRF Meteorological Simulation Based on Knowledge Graph Structure	Chunxiao ZHANG	M217	2024-08-28 11:15	2024-08-28 11:30	3915
Diagenetic facies characteristics and quantitative prediction via wireline logs based on machine learning	Liqiang ZHANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3917
Machine learning-based approach for intermediate volcanic rock tectonic setting determination.	FengRui JIN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3918
Assessment of the effectiveness of a convolutional autoencoder for digital image-based automated core logging	Jaesung PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3919
Method of Segmenting the Origin of Soil samples in South Korea Using Deep Learning-based Feature Extraction Technology	SUBI LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3920
Integration of Dense Well Network Architecture Unit Geological Knowledge Base into Generative Adversarial Networks for Modeling Reservoir Architecture in Fan Delta	Chao Jiang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3921
Identification method of low-order faults in ultra-deep carbonate rocks based on convolution neural network	Hao LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3922
Improvement of Deep Learning-based Inverse Model with Reconstruction of Dynamic Data	Hayoung KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3923
Fault detection based on 3D seismic images using an integration of GCN and U-Net	Guoqing LU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3925
Seismic attribute optimization and fracture prediction model establishment based on artificial intelligence-A case study of dense sandstone reservoirs in the Northern Ordos Basin	Ziyi YANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3927
Carbonate Lithofacies Logging Identification Based on Machine Learning: A Case Study of Longwangmiao Formation in Moxi Area, Sichuan Basin	Mingqiang LI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3929
S7+S5 General Topics		Session Chair: Scientific Program Committee			
Development and Application of an Intelligent QA System for Knowledge of Global Petroliferous Basins	LI DAWEI	M217	2024-08-28 08:00	2024-08-28 08:15	3931

Title	Presenter	Venue	Start	End	Page
Artificial Intelligence and Machine Learning for the Automated Classification of the Seabed	Umberto DI LAUDO	M217	2024-08-28 08:15	2024-08-28 08:30	3932
Predicting Pegmatite-Derived Lithium Anomaly in Stream Sediment Using Machine Learning Methods: A Case Study of South Korea	Jeong-Ho LEE	M217	2024-08-28 08:30	2024-08-28 08:45	3933
Physics-Guided Unsupervised Deep Learning Approach for the Inversion of Receiver Functions	BIJAYANANDA DALAI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3934
Research on data integration system development for excavation construction equipment fleet management	Skhan Park	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3935
AI in solving geological problems using the example of uranium deposits in Kazakhstan	Abish SHARAPATOV	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3936
A new approach of mineral targeting in a concealed shear zone complex by Knowledge-Driven multi-thematic Mineral Prospectivity Mapping	PRASHANTH KUMAR K	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3938
Intelligent Identification Technology for Sandstone Thin Sections	Yili REN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3940
A study on the analysis and prediction model of lime dosage for artificial intelligence-based mine drainage treatment	SEONG-SOOK PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3942
The intelligent identification and regional capacity estimation of submarine polymetallic nodules based on Segment Anything Model	Jingpeng LIU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3944
T34 Energy and Carbon Neutrality					
S1 Geothermal energy, geoenergy, geopower, geoheat, earth energy		Session Chair: Scientific Program Committee			
Borehole Thermal Resistance Estimation and Optimization for In-Situ Borehole Heat Exchangers	Byoung Ohan SHIM	M214	2024-08-26 16:00	2024-08-26 16:15	3946
Interdisciplinary and shared 3D geomodels of the Los Humeros and Acoculco geothermal systems (Mexico)	Philippe CALCAGNO	M214	2024-08-26 16:15	2024-08-26 16:30	3947
CEEGS - Novel CO2-based electrothermal energy and geological storage system	Marko KOMAC	M214	2024-08-26 16:30	2024-08-26 16:45	3949
On Policies and Mechanisms for Collaborative Promotion of Electricity Market and Carbon Market under the Dual Carbon Goals	Jia LIU	M214	2024-08-26 16:45	2024-08-26 17:00	3953
Geothermal Water Chemistry and Water Rock Interaction in the Olkaria Geothermal Reservoir, Naivasha Kenya.	Edwin Wafula WANYONYI	M214	2024-08-26 17:00	2024-08-26 17:15	3954
Transgeo Project - How to reuse abandoned oil and gas exploration wells, opportunities and constraints in Hungary	Ferenc FEDOR	M214	2024-08-26 17:15	2024-08-26 17:30	3955
Hydrochemical features of geothermal waters in the Namaqua-Natal Province, South Africa	Musarrat SAFI	M214	2024-08-26 17:30	2024-08-26 17:45	3956
The Impact of Fluid-Rock Interaction on Environment in Geothermal Sites of Kuril-Kamchatka Island Arc	JULIA Vladimirovna FROLOVA	M214	2024-08-26 17:45	2024-08-26 18:00	3951
Fracture-matrix interactions of deep geological systems in the context of energy geosciences and carbon management	Qinhong Hu	M214	2024-08-26 18:00	2024-08-26 18:15	3957
Optimal Selection and Development Plan Design for Buried Hill-Type Hot Dry Rock Targets in the Jiyang Depression	Shaozheng Wang	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3959
Feasibility analysis of thermal solar energy storage in heterogeneous deep aquifer	Yating W	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3960
The potential for GigaWatt-Hour Subsurface Thermal Energy storage in Mine shafts	Zoe SHIPTON	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3961
New understanding of Mesozoic-cenozoic tectonic features and geothermal potential evaluation in Weibei Basin	Xiaoxin SHI	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3962
Characterizing geothermal heat pump system in relation to thermal property of different rocks by laboratory and field tests	Youngjin KIM	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	3963
S2 Offshore renewable energy systems and submarine geohazards		Session Chair: Shinji SASSA			
[Keynote] Submarine Geohazards Resistant Design Concept for Anchors and Cables of Floating Offshore Wind	Shinji Sassa	M214	2024-08-27 08:00	2024-08-27 09:30	3965
Toward Sustainable Development of Offshore Wind Power at Active Margins -Importance of Submarine Geohazard Risk Assessment-	Yasukuni Okubo	M214	2024-08-27 08:30	2024-08-27 08:45	3964
Numerical simulation of the flow impact due to submarine landslide exerting on offshore wind turbines with a monopile type foundation	Kazuki MURATA	M214	2024-08-27 08:45	2024-08-27 09:00	3967
Wave-Induced Liquefaction and the Stability of Offshore Structures in Seabed Soils in a Drum Centrifuge	JUNJI MIYAMOTO	M214	2024-08-27 09:00	2024-08-27 09:15	3968
Assessment of Submarine Geological Risks to Offshore Wind Power in Japan Coastal Areas	Koki KIMURA	M214	2024-08-27 09:15	2024-08-27 09:30	3969
Seismic characteristics of Changyun Rise western offshore central Taiwan (eastern Taiwan strait) and their possible connections to Late Pleistocene - present Choshui River system	Yi Hao WANG	Exhibition Hall	2024-08-27 09:15	2024-08-27 09:30	3970
S3 Assessment of innovation necessary for sustainable use of geothermal resources		Session Chair: Yasukuni Okubo			
Significance of Strong Amplitude Reflectors Observed in Geothermal Areas for Deep Geothermal Resource Exploration	Jun MATSUSHIMA	M214	2024-08-28 08:00	2024-08-28 08:15	3973

Title	Presenter	Venue	Start	End	Page
DEVELOPMENT OF THE RENEWABLE GEOTHERMAL ENERGY IN UZBEKISTAN	Elena Aleksandrovna GOLOVKO	M214	2024-08-28 08:15	2024-08-28 08:30	3974
Porous media heat transport experiments reveal local thermal non-equilibrium (LTNE) and non-uniform flow	Haegyeong LEE	M214	2024-08-28 08:30	2024-08-28 08:45	3975
Experimental investigation of formation damage potential during thermal water reinjection on Upper Miocene (Pannonian) sandstones from Szentes geothermal field, Hungary	Péter János KORONCZ	M214	2024-08-28 08:45	2024-08-28 09:00	3976
Study of seasonal characteristics of near-surface geo-temperature obtained by long-term monitoring in Japan	Osamu MATSUBAYASHI	M214	2024-08-28 09:00	2024-08-28 09:15	3977
Application of play fairway analysis to identifying geothermal prospect areas in Sulawesi Island, Indonesia	Angga Bakri PRATAMA	M214	2024-08-28 09:15	2024-08-28 09:30	3978
Incorporating Mineral Compositions in Shallow Wells into Multicomponent Geothermometer to Improve Reservoir Temperature Estimation in the Patuha Field, Indonesia	Brenda Ariesty Kusumasari	M214	2024-08-28 09:30	2024-08-28 09:45	3979
The role of the upper crustal thermal structure in defining the global Golden Zone of hydrocarbons	Carlos Alberto Vargas	M214	2024-08-28 09:45	2024-08-28 10:00	3980
Turning point of geothermal resources development in the world	Yasukuni Okubo	M214	2024-08-28 10:00	2024-08-28 10:15	3981
Combination of Fuzzy Logic and Geostatistics for Detecting Potential Zones of Geothermal Resource over Java Island, Indonesia through Multi-Sensor Satellite Image Data	Tedi Atmapradhana	M214	2024-08-28 10:15	2024-08-28 10:30	3985
Thermolithospheric Model (THERMOMAG) to Curie Isotherm Calculations	Suze Nei Pereira GUIMARAES	M214	2024-08-28 10:30	2024-08-28 10:45	3971
PTA and TTA the fundamental difference in Geothermal prospect well test	Fathia ABDI ATTEYE	M214	2024-08-28 10:45	2024-08-28 11:00	3984
S4+S6+S7 Critical Minerals Governance for Carbon Neutrality		Session Chair: Yasukuni Okubo			
Underground Resources and their Uses in the Energy Transition: Hydrocarbon exploration, geothermal energy, and natural gas, CO2 and H2 storage in the Polish Basin as a part of the Central European Permian–Mesozoic Basins.	JAROSLAW ZACHARSKI	M214	2024-08-28 11:00	2024-08-28 11:15	3982
Carbon emission reduction: Contribution of geothermal energy and practice in China	Liqiong JIA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3986
Colombia's natural hydrogen potential: first exploration insights	Valeria RAMIREZ JUYA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3988
Sustainable and ethical mining: future challenges and new perspective	Daniele SPIZZICHINO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3990
Research on the Effect of Pressure on Thermal Cracking of Immature/Low Mature Source Rocks	Fengtian BAI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3992
Oxidative pyrolysis characteristics and kinetic analysis of low-medium maturity organic rich shale	Sunhua DENG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3994
Design and simulation of a high-efficiency cooling system for high temperature drilling fluid	Rui JIA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3995
Projection of natural gas demand in China based on a hybrid model from sector perspective under carbon-neutral strategy	Xiaoqian GUO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3997
Magnetite powder as an enhancer in biogasification of phenolic pollutants	Minjae KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3998
A spectroscopic assessment of the microstructural evolution in a suite of Indian coals and their potentiality for energy storage applications	Archchi Sarkar	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	3999
S5 Unconventional Oil and Gas Resources & CO2 Geological Sequestration		Session Chair: Dameng LIU			
Characterization of pore structure in semi-deep and deep lacustrine tight sandstones: A case study of the Triassic Chang 6 in Longdong area, Ordos Basin, NW China	Taping He	M214	2024-08-27 09:30	2024-08-27 09:45	4000
Two decades of research on injection-induced seismicity: What have we learned?	David William EATON	M214	2024-08-27 09:45	2024-08-27 10:00	4001
Applications of low-field NMR techniques in CO2 sequestration in hydrocarbon reservoirs	Yanbin YAO	M214	2024-08-27 10:00	2024-08-27 10:15	4003
Advancements in the Exploration and Production of Coal-Associated Unconventional Natural Gas in China: Geological Insights and Technological Innovations	Dameng LIU	M214	2024-08-27 10:15	2024-08-27 10:30	4004
Material Balance Equation for CO2 Storage Capacity Estimation in Saline Aquifer	Sangkeon PARK	M214	2024-08-27 10:30	2024-08-27 10:45	4009
Anisotropic reservoir characteristics influencing the CO2 sequestration behavior in shale with simultaneous enhanced gas recovery and a case simulation	Li LI	M214	2024-08-27 10:45	2024-08-27 11:00	4010
Exploration of shale gas from lower Gondwana shale beds of Jharia Coalfield, India– a potential game changer in clean energy domain	KAUSIK KUMAR GHOSH	M214	2024-08-27 11:15	2024-08-27 12:00	4014
Experimental Study on Interaction of Sc-CO2 with Feldspar and Clay Minerals and its Implication to Carbon Sequestration in Sandstone Reservoirs	Yiming Luo	M214	2024-08-27 14:15	2024-08-27 14:30	4011

Title	Presenter	Venue	Start	End	Page
Effect of the surfactant on the storage ratio of supercritical CO2 in pore spaces of the subsurface CO2 reservoir rock: based on laboratory experiments	Jeonghyeon BYEON	M214	2024-08-27 14:30	2024-08-27 14:45	4007
Effect of intraformational mudstone on CO2 plume migration and distribution: Insights from Sleipner geological storage project	Huixing ZHU	M214	2024-08-27 15:00	2024-08-27 15:15	4005
Comparison of Gas-bearing Parameter Evaluation Methods for Deep Shale Based on Pressure-holding Coring Technique	Xiao LI	M214	2024-08-27 15:15	2024-08-27 15:30	4024
Utilization of porous media for CO2 and H2 storage in Hungary	Gyorgy FALUS	M214	2024-08-27 15:30	2024-08-27 15:45	4021
A novel method to enhance hydrate production and CO2 sequestration in clayey silty reservoir via splitting grouting	Xiaochu WANG	M214	2024-08-27 16:00	2024-08-27 16:15	4020
Pore-scale Investigation of the Effect of Surfactant on Storage Efficiency in CO2 Geosequestration	Chan Hee KIM	M214	2024-08-27 16:15	2024-08-27 16:30	4019
Fracture Diagnosis and Inter-Well Interaction Analysis - Correlating Fiber Optic Data with Coupled Geomechanics-Thermal-Flow Simulations	Juliana Y Leung	M214	2024-08-27 16:30	2024-08-27 16:45	4017
Structural deformation and microstructure evolution of marine shale from the upper Yangtze region of China	Yiwen JU	M214	2024-08-27 16:45	2024-08-27 17:00	4016
Preliminary assessment of CO2 storage capacities in the northern portion of the offshore Orange Basin, South Africa.	Nangamso DUNGA	M214	2024-08-27 17:00	2024-08-27 17:15	4026
Molecular simulation of CO2 injection in methane-bearing coal models with different pore structures	Ruikang CUI	M214	2024-08-27 17:15	2024-08-27 17:30	4012
Nano-petrophysical studies for energy geosciences in the context of carbon neutrality.	Qinhong Hu	M214	2024-08-27 17:30	2024-08-27 17:45	4028
Acoustic Simulation Study of Coal Rock	Xiaojuan SUN	M214	2024-08-27 17:45	2024-08-27 18:00	4023
Carbon fixation mineral—Geological characteristics and synthetic experiments of Dawsonite	Yangchen ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4029
Multi-objective optimization of impure CO2-EOR implementation using CNN-GRU neural network and NSGA-II algorithm: a case study on H59 block of Jilin oilfield China	guangxu CHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4030
Geochemical Characterization of Pimienta Formation, Mexico as a Potential Hydrogen Source	Alexis Rosa NUMMER	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4031
Comprehensive division of exploration and development units: case studies from three blocks in the southern Qinshui Basin	HUI WANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4033
Evaluation of Multi-scale Natural Fractures in Coalbed Methane Reservoirs	Yidong CAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4034
Numerical Simulation Study on the Effect of Horizontal Well Reservoir Stimulation for Gas Hydrate Production	Xiaoyang LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4035
Early-Stage Risk Assessment for a Potential Commercial-Scale Geological Carbon Storage Site in Utah, USA	Ting XIAO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4036
Microscale gas occurrence mechanism in coalbed methane reservoirs	Fengrui SUN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4037
Effect of SCCO2-H2O-Coal Reaction on the Pore Structure of High-rank coal	Junyan Jun ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4038
Monitoring methane gas emissions in coal mine areas of North Korea based on Sentinel-2 satellite data	Minju KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4039
Simulation study of the high-temperature nitrogen injection in-situ conversion process: a case study in Songliao Basin shale formation	Chaofan ZHU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4040
Numerical Simulation of Oil Recovery Performance and Long-term CO2 Storage Potential after Different CO2-EOR Operations	Zejin FAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4041
Autothermic Pyrolysis in situ Conversion Process for Oil Shale Recovery	Wei GUO	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4042
Study on promoting mechanism of electric field on pyrolysis and seepage of oil shale products	Qiang LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4043
Altering Pore Morphology of Organic-Rich Shale through SC-CO2 Exposure	Ogochukwu OZOTTA	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4044
Unveiling the Sub-10 Nanometer Realm: Innovative FIB-HIM Approach to Shale Nanopore Characterization	Jianguo WU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4045
Formation dry-out from CO2 injection into coal seam: Salt precipitation and injectivity alteration	Xiaoxiao SUN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4046
Influence of sediment properties on methane hydrate enrichment in fine-grained sediments	Chenyang BAI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4047
The Geochemical characteristics and Genetic mechanism of tight gas in Shahezi Formation,North Songliao Basin, China——Take Xujiaweizi Fault Depression as an example	YiXuan RAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4048
Sensitivity analysis of non-condensable gas in SAGP method on 3-dimensional heterogeneous oil sands reservoir	Sunghyun KIM	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4049
Prediction of CO2 flooding channels based on seismic azimuthal anisotropy	Mei YANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4051
Investigation of Characteristics of Gas Hydrate Decomposition under Microwave Stimulation	Baochang Liu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4053
Fatigue life analysis of oil shale in-situ conversion combustion heater	Shui haoche	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4054
Numerical Simulation Study on the Influence of Intermittent Gas Injection on the in-situ Conversion Development Effect of Oil Shale Autothermic Pyrolysis	Yijian ZENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4055

Title	Presenter	Venue	Start	End	Page
Numerical Simulation Study on the Impact of Complex Fracture Network on In-Situ Conversion of Oil Shale	Yanwei LI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4056
Evaluation of Nong'an oil shale reservoir stimulation based on gas injection	Qingfeng BU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4057
Carbon Dioxide Storage Potential of Cenozoic Saline Aquifers in the South Yellow Sea Basin	Yong YUAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4058
Experimental Study and Numerical Simulation of Rock Fracturing Based on High Voltage Electric Pulse	LI XIAOLE LI XIAOLE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4059
Evaluation of CO2 Storage Potential in Offshore East Sea, Korea	Eunsil Jung	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4060
Evolution of fluid occurrence states during oil shale pyrolysis under inert and oxidative conditions	Junfan PAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4061
Research on the inherent mechanism of rock mass deformation of oil shale in-situ mining under the condition of thermal-fluid-solid coupling	Shuo ZHANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4062
Effect of decrease in pore water salinity induced by depressurization in clayey silt gas hydrate reservoirs on the migration characteristics of illite	Jiang LEI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4063
Enhancement on the development of methane hydrate in the clayey silty reservoir by stratified split grouting	Hangkai Chen	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4064
Fracture propagation and evaluation of dual wells, multi-fracturing, and split-time in Fuyu oil shale	Bin Zhu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4066
Calculation method and application of cap rock's effective thickness of X Gas Reservoir	Zhengchun SHEN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4067
Hydrocarbon migration and accumulation in shale play	Rujiao CHENG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4068
A novel approach for predicting in-situ stress in coal reservoirs based on acoustic emission: Analysis, comparison, and application	Shuheng TANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4070
Identifying Miocene sedimentary rocks for CO2 storage in the Gunsan Basin	CHANGYOON LEE	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4072
T35 Geoscience and Policy					
S2+S4 / T22-S4 Geological Survey Organizations and Land Use Planning: From Geoscience Data to National Policy		Session Chair: Christopher Keane, Young Joo LEE			
The Australian national geological survey organisation's (Geoscience Australia) provision of geoscience data to inform national policy and decisions using the Digital Atlas of Australia	Steve HILL	M311	2024-08-29 08:05	2024-08-29 08:18	4077
The key role of NGSOs and transnational associations in supporting policy making process for mitigating and adapting to the global climate change	Christophe POINSSOT	M311	2024-08-29 08:18	2024-08-29 08:31	4096
U.S. Invests in Foundational Geoscience Data Collection, Mapping, and Analysis to Inform Infrastructure Policy	David APPLEGATE	M311	2024-08-29 08:31	2024-08-29 08:44	4091
Geological Surveys in Ibero-America and land use planning	Enrique Armando CASTELLANOS ABELLA	M311	2024-08-29 08:44	2024-08-29 08:57	4073
Geological Survey Ireland, supporting national policy through geoscience on land and at sea.	Koen M VERBRUGGEN	M311	2024-08-29 08:57	2024-08-29 09:10	4082
Public geoscience: a foundation for strategic land use decisions in Canada	Sonia TALWAR	M311	2024-08-29 09:10	2024-08-29 09:23	4087
The Important of Geoscience Data for Land Use Planning in Malaysia	Zamri bin RAMLI	M311	2024-08-29 09:36	2024-08-29 09:49	4101
Geoscience information in Dutch land use planning: showcase for comprehensive planning?	Tirza van DAALEN	M311	2024-08-29 09:49	2024-08-29 10:02	4084
Role of Czech Geological Survey in Siting of Deep Geological Repository of Radioactive Waste	Zdenek Venera	M311	2024-08-29 10:02	2024-08-29 10:15	4100
Contribution of geoheritage and geoconservation research to land use planning and new policies in the post-eruptive recovery phase of 2021 Tajogaite volcano (La Palma Island, Spain)	Juana VEGAS	M311	2024-08-29 10:15	2024-08-29 10:28	4078
Navigating Extreme Landslide Events: Insights from Slovenia's August 2023 Disaster and the Role of the National Geological Survey	Miloš BAVEC	M311	2024-08-29 10:28	2024-08-29 10:41	4089
New Arabian Shield Lithostratigraphic and Lithodemic Code (ASLLC) and its Application to the Terranes of the Arabian Shield	Alan S. Collins	M311	2024-08-29 10:41	2024-08-29 10:54	4075
Subsurface environment, a key asset for the global ecological transition	Christophe POINSSOT	M311	2024-08-29 14:35	2024-08-29 14:48	4094
The importance of raw materials for the Energy Transition	Teresa PONCE DE LE ÃO	M311	2024-08-29 14:48	2024-08-29 15:01	4098
The European Critical Raw Materials Act – How can geoscience programmes support the Act and build collaborations	Ana Luisa LAVADO	M311	2024-08-29 15:01	2024-08-29 15:14	4080
EU International Centre of Excellence on Sustainable Resource Management in support of the United Nations Resource Management System	Miloš BAVEC	M311	2024-08-29 15:14	2024-08-29 15:27	4093
OneGeology Projects: Climate Action, Geohazards and of course, the Global Geological Map	Steve Hill	M311	2024-08-29 15:27	2024-08-29 15:40	4086
Developing QGIS Plugins for 3D Geological Modelling	Michel M. NZIKOU	M311	2024-08-29 15:40	2024-08-29 15:53	4074
Professionals in Earth Sciences in municipal administrations, a contribution to the development of the territory: a case study in Colombia, South America	Clemencia GOMEZ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4102
OneGeology's impact: shaping the development of digital cartography in the Polish Geological Survey	Katarzyna JÓŹWIK	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4103

Title	Presenter	Venue	Start	End	Page
PanAfGeo: A unique pan-African training programme for African Geological Surveys	Nicolas CHARLES	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4105
IGME's contribution to the Critical Raw Materials pan-European map: GSEU project	Iván MARTÍN-MÉNDEZ	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4107
What we have learned from operating OneGeology Portal	Amaya FUENZALIDA VELASCO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4108
The national geological service of Senegal : an instrument for managing geoscience data that benefits policy makers.	Raymond SAGNA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4109
S3+S1+S6 Responsible Mining of Critical Minerals and the Importance of Environmental Justice		Session Chair: Adam Simon			
SOCIAL REPORT OF THE GEOLOGICAL SERVICE OF BRAZIL, AN ESG TOOL	Patricia DURINGER Jacques	M317	2024-08-29 08:00	2024-08-29 08:15	4111
Geothermal energy research supporting national policy and regulation; a European case study from Ireland	Aoife K. BRAIDEN	M317	2024-08-29 08:15	2024-08-29 08:30	4113
Geoscience for Sustainability – A new initiative to promote the role of geosciences in society	Jonathan ARTHUR	M317	2024-08-29 08:30	2024-08-29 08:45	4117
Integrated geoscience mapping toward minerals and energy development: a case study for lithium prospectivity in the Northern Cape of South Africa	Taufeeq DHANSAY	M317	2024-08-29 08:45	2024-08-29 09:00	4121
Insights on the evolution of mineral policies, acts, rules and their association with mineral targeting geosciences in India	Debkumar BHATTACHARYYA	M317	2024-08-29 09:00	2024-08-29 09:15	4119
Geoscience Policy Advocacy for the Public Good: Making an Impact through Policy!	Munira Raji	M317	2024-08-29 09:15	2024-08-29 09:30	4115
Communicating with Non-Scientists: A Review of Select EU Horizon Projects and their Degree of Public Transparency	Maureen Gallagher	M317	2024-08-29 09:30	2024-08-29 09:45	4122
IGCP 735 project: Rocks and the Rise of Ordovician Life	Wenhui Wang	M317	2024-08-29 09:45	2024-08-29 10:00	4123
Intergovernmental Action on Sustainability and the Role of Geoscience	Janice Lachance	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4124
The Brazilian Geological Survey: Unveiling a World of Geodiversity and Scientific Expertise for Global Collaboration	Deborah MENDES	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4125
S5 Empowering women in geoscience for gender equality		Session Chair: Heejung Kim			
[Keynote] Advancing Earth Science and women's equity through research, community building and professional societies	Carol FINN	M211	2024-08-28 16:20	2024-08-28 16:40	4130
East to West collaboration for a gender equality in Geosciences	Minha LEE	M211	2024-08-28 16:40	2024-08-28 16:55	4127
GeoLatinas: six years embracing, empowering and inspiring Latinas in Earth and Planetary Sciences	Monica Alejandra GOMEZ CORREA	M211	2024-08-28 16:55	2024-08-28 17:10	4128
Africa-Europe: working together to close the gender gap in Geosciences.	Lola PEREIRA	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4132
T36 Management of Radioactive Resources and Waste					
S1+S5 Advances in natural and engineering barriers for underground nuclear waste repositories		Session Chair:			
Inversion of Barcelona Basic Model Parameters for Thermo-Hydro-Mechanical Simulation of High-Level Radioactive Waste Disposal System	Yeongju KIM	M212	2024-08-29 09:30	2024-08-29 09:45	4134
Micro CT and NMR studies in the very compact Boda Claystone, in connection with the Hungarian HLW project	Ferenc FEDOR	M212	2024-08-29 09:45	2024-08-29 10:00	4135
Microbial Reactions by Bentonite Indigenous Microbes under Varied Temperatures and Irradiation Conditions	Kanghyun PARK	M212	2024-08-29 10:00	2024-08-29 10:15	4136
Investigation of Characteristics of Bentonite Samples in Natural Analogue Study Sites	Yoonah BANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4137
3D and 4D insights into barrier behaviour	Katherine DOBSON	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4138
Analysis of the Current Status of Siting Criteria and Factors for High-Level Radioactive Waste Disposal in Leading Countries	Taeyoo NA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4139
Characterization of Ca-type bentonite in contact with corrosion product of copper canister	Gha-Young Kim	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4140
Site Characterization and Investigation Requirements (draft) for High-Level Radioactive Waste Disposal Facilities	Hyeondong Woo	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4141
R&D of KAERI for development of base technologies for demonstration of the deep geological system	Geon Young KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4143
Enhancing HLW Disposal Safety Through Global NA Study insights	HunSuk IM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4145
Integrating Advanced Technologies and Safety for a Susainable Spent Nuclear Fuel Waste management	HunSuk IM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4147
Investigating Measurement Methods for Grain Bulk Modulus of Sandstone: An Experimental Approach	Min-Jun KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4149
S2 Investigation and evaluation techniques related with nuclear power plants and waste disposal sites		Session Chair:			

Title	Presenter	Venue	Start	End	Page
[Keynote] Current Status and Future Outlook on IAEA Safety Standards Development and Research Regarding the Site Safety for Nuclear Facilities	Heanu LEE	M212	2024-08-28 14:30	2024-08-28 14:45	4151
Kinematic and Paleostress Analysis for Long-term Structural Evolution: A Preliminary Analysis in the KURT Site	Ho-Seok Choi	M212	2024-08-28 14:45	2024-08-28 15:00	4150
Volcanic Tephra-Fallout Hazards and the Safety of Nuclear Installations	Hyun Woo LEE	M212	2024-08-28 15:00	2024-08-28 15:15	4153
Integrating multi-disciplinary data to evaluate a potential deep geological repository site	Jakub KRYL	M212	2024-08-28 15:15	2024-08-28 15:30	4155
GeM-DB – A searchable database, linking exploration objectives and geoscientific methods for the German nuclear waste repository siting process	Thies BEILECKE	M212	2024-08-28 15:30	2024-08-28 15:45	4157
Integrated analysis of deep brittle structures using borehole images and drill cores for high-level radioactive waste disposal	Ji-Min CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4159
Geochemical and Geochronological Study of the Crystalline Rocks through Boreholes in the KURT Site: Implications for Long-term Evolution of a Deep Geological Repository	Nak Kyu KIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4160
Morphostructural analysis of the LIDAR terrain model applied in the selection of a site for the Deep Geological Repository for Radioactive Waste	Jan JELÍNEK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4161
GPR, a fundamental tool for 3d mapping of the complex internal salt structures by investigations in drifts and boreholes	Thies BEILECKE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4162
Investigation of host rocks and geotechnical barriers for the disposal of radioactive waste by means of Electrical Resistivity Tomography (ERT)	Thies BEILECKE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4163
Comparison of geological and mechanical properties of crystalline and sedimentary rocks through deep drilling cases	Dae-Sung Cheon	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4164
Applying deep learning to detect fractures from GPR data	Ain LEE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4165
Investigating Deep Groundwater Recharge Processes: A Combined Isotopic, Hydrochemical, and GIS Methodology	JAEHOON CHOI	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4167
Characteristics of radiogenic heat production rate in fractured rock mass	Yeonguk JO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4168
S3 Transport of radionuclides in deep geological repositories and nuclear-related facilities		Session Chair: Benny (Chuan-Pin) LEE, Young-Jin Park			
[Keynote] Overview of research and development (R&D) activities on radionuclide migration in Taiwan	CHUAN-PIN LEE	M212	2024-08-28 16:00	2024-08-28 16:15	4169
Assessment of Water-Rock Interactions of Uranium through Laboratory Batch and Column Experiments	Sung-Wook JEEN	M212	2024-08-28 16:15	2024-08-28 16:30	4170
Characterization of radionuclide mobilization using environmental tracers at natural analogue site in Boeun, South Korea	Ye Ji KIM	M212	2024-08-28 16:30	2024-08-28 16:45	4171
Methodology development for optimal remediation strategies for nuclear facility sites	In-Ho YOON	M212	2024-08-28 16:45	2024-08-28 17:00	4172
A current status of natural analogue studies in Korea for high-level radioactive waste disposal	Ji-Hun RYU	M212	2024-08-28 17:00	2024-08-28 17:15	4173
Multiple sulfur and uranium isotope compositions of uraniferous slates in the Bibong Formation of the Okcheon Metamorphic Belt	Eunje OH	M212	2024-08-28 17:15	2024-08-28 17:30	4174
Examining Uranium Behavior Through Column Experiments Using Artificial Groundwater and Coaly Slate from a Natural Analogue Study Site in Korea	Soyeon LIM	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4175
Hydrochemical Characteristics of Deep Groundwater by Depth in Granite site for Disposal of High-Level Radioactive Waste	JIWON PARK	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4177
Examination of Uranium Migration within Bentonite Employing the Reactive Transport Model	Won Woo YOON	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4178
Investigation of geochemical evolution and radionuclide migration in engineered barrier systems using an adaptive process-based total system performance assessment framework	Jeonghwan HWANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4179
S4 Techniques for assessment and control of nuclide behavior in the HLW geological repository		Session Chair: Minhee LEE			
Sorption characteristics of the cesium on the improved coal mine drainage treated sludge (CMDS) by the addition of Na and S	Soyoung JEON	M212	2024-08-29 08:00	2024-08-29 08:15	4180
Gas and nuclide migration model study by using parameter values derived from laboratory experiments	Danu KIM	M212	2024-08-29 08:15	2024-08-29 08:30	4182
Characterization of Granitic Groundwater Colloids in KAERI Underground Research Tunnel for Evaluating Radionuclides Transport	Sang-Ho LEE	M212	2024-08-29 08:30	2024-08-29 08:45	4184
Sorption Mechanisms and Thermodynamics of Highly Soluble Fission Products onto Ca-type Bentonil-WRK Montmorillonite	Seonggyu CHOI	M212	2024-08-29 08:45	2024-08-29 09:00	4185
Assessing nuclides migration across multi-barrier interfaces using reactive transport models	Heewon JUNG	M212	2024-08-29 09:00	2024-08-29 09:15	4187
Interrogating reactive surface distribution at the pore-scale using dual tracer breakthrough curves	Sunwong LIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4188
Effect of gas originated from the deep geological SNF (spent nuclear fuel) repository on the sorption of Cs (I) and Sr (II) on bentonite	Daehyun SHIN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4189
Experimental Investigation into Nuclide Diffusion on Compacted Bentonite under the Influence of Reactive Gas	Jin-Seok KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4191

Title	Presenter	Venue	Start	End	Page
Preliminary results of nuclide migration and retardation in engineering-scale natural fractured rock	Seonyi NAMGUNG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4193
Accelerating geochemical calculations in reactive transport simulations with an artificial neural network based surrogate model for nuclear waste repository management	Yehoon KIM	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4194
T37 Deep-Time Digital Earth: IUGS DDE Sessions					
S1 Evolution of life and biodiversity changes through deep time		Session Chair: Shuzhong Shen			
[Keynote] Mesozoic origin and evolution of coccolithophores documented by their biodiversity and calcification	ELISABETTA ERBA	C110	2024-08-28 14:30	2024-08-28 14:45	4201
[Invited] Reconstructing High-Resolution Biodiversity Patterns in Deep Time: Innovations, Challenges, and Future Directions	Junxuan FAN	C110	2024-08-28 14:45	2024-08-28 15:00	4200
An enigmatic macrofossil from the terminal Ediacaran Liuchapo Formation in South China	Qing TANG	C110	2024-08-28 15:00	2024-08-28 15:15	4205
A Deep Learning Approach to Synthesizing Phanerozoic Paleoclimate and Biogeochemical Cycles	Dongyu ZHENG	C110	2024-08-28 15:15	2024-08-28 15:30	4199
The Basal Emsian boundary – the only pending stage issue in the Devonian stratigraphy	Ladislav SLAVÍK	C110	2024-08-28 15:30	2024-08-28 15:45	4195
Foraminiferal biodiversity changes to interpret the paleoenvironmental perturbation across the Late Cretaceous Oceanic Anoxic Event 2 at southern high latitudes (IODP Sites U1513 and U1516, SE Indian Ocean)	Maria Rose PETRIZZO	C110	2024-08-28 15:45	2024-08-28 16:00	4212
Heterogeneous selectivity and morphological evolution during the Permian-Triassic mass extinction	Xiaokang Liu	C110	2024-08-28 16:00	2024-08-28 16:15	4198
Early Palaeozoic biodiversifications: Plus ça change	David A. T. HARPER	C110	2024-08-28 16:15	2024-08-28 16:30	4211
Palaeo-environmental insights into late Ediacaran "mass extinctions"	Brennan O'Connell	C110	2024-08-28 16:45	2024-08-28 17:00	4206
Unraveling Marine Biodiversity Dynamics in North China during the Middle-Late Cambrian: Insights from a High-resolution Species-level Richness Analysis	Yujie Shi	C110	2024-08-28 17:00	2024-08-28 17:15	4203
Morphological complexity as a potential predictive indicator of evolutionary rates in ammonoids	Luyi Miao	C110	2024-08-28 17:15	2024-08-28 17:30	4207
Building a numerical high-resolution geological timeline	Shuzhong SHEN	C110	2024-08-28 17:30	2024-08-28 17:45	4197
Recognition and timing of Early-Middle Devonian extinction events in South Polar regions	Cameron Roy PENN-CLARKE	C110	2024-08-28 17:45	2024-08-28 18:00	4209
Pioneering Data-Driven Discoveries from DeepBone.org	Zhaohui PAN	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4214
Latitudinal Shift Patterns of Taxa Through the Phanerozoic	Shuhan Zhang	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4216
S2 Quantifying plate tectonics and deformation in four dimensions		Session Chair: Shaofeng Liu			
[Keynote] Topography and deformation of the Polar regions measured with thermochronometry	Matthew Fox	C110	2024-08-27 08:00	2024-08-27 08:15	4220
[Invited] Toward a “best-fit” tectonic reconstruction for the Caroline Plate: Oceanic plateau-subduction zone interaction as a driver for plate boundary reorganization?	Samuel MARTIN	C110	2024-08-27 08:15	2024-08-27 08:30	4218
Dynamic Linking of Progressive Exhumation to Mendocino Triple Junction Migration	yudan SI	C110	2024-08-27 08:30	2024-08-27 08:45	4217
Non-cylindrical Slab Subduction and Tearing beneath Southern Iberia	Pengfei MA	C110	2024-08-27 08:45	2024-08-27 09:00	4221
High-elevation Tibetan Plateau before India–Eurasia collision recorded by triple oxygen isotopes	Xiangrui Liu	C110	2024-08-27 09:00	2024-08-27 09:15	4222
Tectonic and topographic evolution of the Eastern Himalayan Syntaxis	Zhicheng Yu	C110	2024-08-27 09:15	2024-08-27 09:30	4223
S3 Deep probing of 3D-4D lithospheric architecture and metallogenic processes		Session Chair: DDE			
[Keynote] Archean lithospheric mantle beneath Neoproterozoic Central Asia Orogenic Belt: significance of Archean lithosphere in the evolution of younger terranes	Kuo-Lung WANG	C110	2024-08-28 08:00	2024-08-28 08:20	4225
Lithospheric thermochemical structure beneath the southwestern Central Asian Orogenic Belt from joint inversion	Xuewei BAO	C110	2024-08-28 08:20	2024-08-28 08:35	4237
The crustal and uppermost mantle Vs structure of the middle and lower reaches of the Yangtze River Metallogenic Belt: implications for metallogenic process	Yingjie YANG	C110	2024-08-28 08:50	2024-08-28 09:05	4224
Water Reservoirs and Speciation in the Lithospheric Mantle	Halimulati ANANUER	C110	2024-08-28 09:05	2024-08-28 09:20	4229
[Invited] Dense passive source seismic array reveals detailed shallow lithospheric structures: a case study from Western Australia	Huaiyu YUAN	C110	2024-08-28 09:20	2024-08-28 09:40	4236
[Invited] Kinematics, Tectonic Events and Orogens	Manuel Pubellier	C110	2024-08-28 09:55	2024-08-28 10:15	4232
Crustal architecture of the Newfoundland Appalachians and its control on metallogeny	Chaoyang WANG	C110	2024-08-28 10:15	2024-08-28 10:30	4227
Continental growth and orogenic types：Big data of magmatic rocks	TAO WANG	C110	2024-08-28 10:30	2024-08-28 10:45	4228

Title	Presenter	Venue	Start	End	Page
Crustal modification influenced by multiple convergent systems: Insights from Mesozoic magmatism in northeastern China	He HUANG	C110	2024-08-28 10:45	2024-08-28 11:00	4231
Geochronology and geochemistry of metamorphic rocks in the Khutag Uul block of the Khatanbulag Massif, South Mongolian Orogenic Belt: Timing of formation and metamorphism and tectonic implications	Narantsetseg TSERENDASH	C110	2024-08-28 11:00	2024-08-28 11:15	4233
Comparative Orotomy of the Archean Superior, North China, and Phanerozoic Altaid orogenic systems	Tim Kusky	C110	2024-08-28 11:15	2024-08-28 11:30	4234
Petrogenesis of late Carboniferous garnet-bearing, strongly-peraluminous granites in the West Junggar oceanic arc, NW China: implication for crustal maturation and rapid supracrustal recycling	Jiyuan Yin	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4238
Formation, Preservation, and Metallogenic Fertility of Juvenile Crust in the Eastern Tethyan Collisional Orogen	Zengqian HOU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4239
Geophysical data constraint on the nature of the basement of the Junggar Basin, the southwestern Central Asian Orogenic Belt	XIAOSAN ZHU	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4240
Early Mesozoic architecture and processes of the Qinling orogen, central China: Nd-Hf isotope mapping	Xiaoxia WANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4241
Evolution of the Proto-Tethys Ocean in the West Kunlun Orogenic Belt, Northwestern Tibet: Insights from the Sub-Arc Crust and Lithospheric Mantle Modification	Zaili TAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4243
S4 Marginal Seas - Past and Future		Session Chair: Joanna dudzinska-nowak			
[Keynote] Competing Natural and Anthropogenic Influences on Sediment Supply to the Global Ocean	Peter Dominic Clift	M312	2024-08-28 14:30	2024-08-28 15:00	4246
A Marine Spatial Data Infrastructure for the Adriatic Sea: Managing Multidisciplinary, Heterogeneous, and Fragmented Geodata with a FAIR Approach to Support Research Life Cycle Management	Federica FOGLINI	M312	2024-08-28 15:00	2024-08-28 15:15	4250
Towards a Marginal Seas Taxonomy	Jan HARFF	M312	2024-08-28 15:15	2024-08-28 15:30	4254
THE 4F NUMERICAL MODEL – a solution for past reconstructions of coastal and glacial dynamics and future simulations	Jerzy Jan FRYDEL	M312	2024-08-28 15:30	2024-08-28 15:45	4247
Numerical paleogeographic modeling of marginal seas – Holocene evolution of Baltic Sea as a case study	Jakub Miluch	M312	2024-08-28 15:45	2024-08-28 16:00	4252
Classification of the morphodynamics of the coast - how we can improve projections of the coastline changes	Joanna DUDZINSKA-NOWAK	M312	2024-08-28 16:00	2024-08-28 16:15	4255
Analyzing the impacts of spatiotemporal coastline changes on sustainable development in the Pearl River Estuary and Hong Kong of northern South China Sea	Yingying LIU	M312	2024-08-28 16:45	2024-08-28 17:00	4258
Linking the past to the future of tide-domianted estuarine changes under human activities and climate changes, case study at the Pearl River Estuary	Junjie DENG	M312	2024-08-28 17:00	2024-08-28 17:15	4245
Regional Relative Sea Level Changes Influenced by Geological Settings: Insights from InSAR Analysis	Zhaoquan Huang	M312	2024-08-28 17:15	2024-08-28 17:30	4249
Characteristics and origin of Quaternary mass transport deposits in the Qiongdongnan basin, northern South China Sea	Tao JIANG	M312	2024-08-28 17:30	2024-08-28 17:45	4257
Mapping the sedimentary change in South China Sea over Last Glacial Cycle and Holocene	Jinpeng ZHANG	M312	2024-08-28 17:45	2024-08-28 18:00	4259
Huatung Basin in West Pacific Marginal Seas: a linkage of West Philippine Sea and South China Sea	Hongfang GAO	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4261
Origin of rapid sedimentation since Late Miocene in the western continental margins of South China Sea	Xinong XIE	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4263
Study on changes of coastline morphology and submarine geomorphology in Caofeidian Area, the North Bohai Sea	Wenqin JIANG	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4265
S5 Knowledge & Data Co-boosted Discovery in the Co-Evolution of Minerals, Microbes and Environments		Session Chair: DDE			
[Keynote] Data-Driven Discoveries in Mineralogy	Robert M HAZEN	C110	2024-08-27 09:30	2024-08-27 10:00	4270
Endolithic microbes catalyze aragonite dolomitization	Geng WU	C110	2024-08-27 10:00	2024-08-27 10:15	4277
AI for minerals: Electron transfer rules under pressure informed by machine learning	Yanzhang LI	C110	2024-08-27 10:15	2024-08-27 10:30	4276
Characterizing early earth environment and searching for signs of life: Data-driven methods to answer questions about Earth and other planets	Anirudh Prabhu	C110	2024-08-27 10:30	2024-08-27 10:45	4269
Mineralogical phases and redox evolution of manganese in Precambrian manganese deposit: Implications for diagenesis	Huan LIU	C110	2024-08-27 10:45	2024-08-27 11:00	4281
[Invited] New phenomena in high-pressure chemistry, and implications for planetary interiors	Artem R. OGANOV	C110	2024-08-27 14:30	2024-08-27 14:45	4274
Advent of different Iron mineral corresponding to the Eh evolving of Precambrian sea water	Yuanfeng CAI	C110	2024-08-27 14:45	2024-08-27 15:00	4278
Mineralogical and Fe Isotopic Constraints on the Origin of the Banded Iron Formations: A Case Study of the Kuruman Formation in South Africa	He Zhang	C110	2024-08-27 15:00	2024-08-27 15:15	4280
A preliminary study on the evolution and ecology of arsenic minerals	Minghao TANG	C110	2024-08-27 15:15	2024-08-27 15:30	4279

Title	Presenter	Venue	Start	End	Page
An expansive Ediacaran lagoon: clay mineralogy and geochemistry evidences for the spatiotemporal extent of evaporitic conditions in the Doushantuo Formation	Shujun HAN	C110	2024-08-27 15:30	2024-08-27 15:45	4266
Photoinduced ring-opening of native sulfur in driving synthesis of prebiotic building blocks	Huan YE	C110	2024-08-27 16:00	2024-08-27 16:15	4282
Evolutionary dynamics of redox-sensitive minerals	ziyi zhuang	C110	2024-08-27 16:15	2024-08-27 16:30	4268
The co-evolution of Earth and life: biosignatures in Earth's mineral networks	Shaunna MORRISON	C110	2024-08-27 16:30	2024-08-27 16:45	4283
Optimizing the infrared radiation performance of tourmaline under γ-ray irradiation	Ming GUO	C110	2024-08-27 16:45	2024-08-27 17:00	4271
Control mechanism of iron speciation on spontaneous polarization of tourmaline containing Fe	Lin ZHOU	C110	2024-08-27 17:00	2024-08-27 17:15	4272
Co-evolving N-Fe redox processes controlled iron minerals in banded iron formation	LIUQIN HUANG	C110	2024-08-27 17:30	2024-08-27 17:45	4273
Phyllosilicates-based nanozymatic microsystems and their significance in geological processes	Shiyong SUN	C110	2024-08-27 17:45	2024-08-27 18:00	4285
Organic minerals: definition, classification and characteristics	Guanghua Liu	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4286
Mineralogical Differences of Ooids and Evolution of Water Environment in Xuanlong-type Iron Ore.	Ganyu TANG	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4288
S6 Time Machine: Earth's deep-time geography -- data, reconstructions, challenges		Session Chair: DDE			
[Keynote] A dynamic evolution of Earth history over the past two billion year	Zheng-Xiang Li	C110	2024-08-29 14:30	2024-08-29 14:50	4299
[Keynote] Orogenic Deformation and Kinematic Reconstructions; Is there a good match?	Camille FRANÇOIS	C110	2024-08-29 14:50	2024-08-29 15:10	4295
The influence of Earth's thermal cycles on instigating significant geological activities	Chun'an TANG	C110	2024-08-29 15:10	2024-08-29 15:25	4308
Models, mysteries and mayhem: Tectonic reconstructions at the dawn of animal life	Marissa J BETTS	C110	2024-08-29 15:25	2024-08-29 15:40	4300
[Keynote] A web-based and data-driven approach to paleogeographic reconstructions: Application to Asian Cenozoic evolution	Guillaume Dupont-Nivet	C110	2024-08-29 15:40	2024-08-29 16:00	4306
Online databases of the geologic formations of Asia and Africa with display onto plate reconstructions	Wen Du	C110	2024-08-29 16:10	2024-08-29 16:25	4290
TimeScale Creator and the TSC Online for Visualizing Earth History	Jaehyuk Lee	C110	2024-08-29 16:25	2024-08-29 16:40	4292
Deep Time Geography of the McArthur-Yanliao Gulf—New ways of looking at a frontier resource-rich basin.	Alan S. Collins	C110	2024-08-29 16:40	2024-08-29 16:55	4297
Palaeogeography of salt deposition prior to the opening of the Central Atlantic Ocean	Julie TUGEND	C110	2024-08-29 16:55	2024-08-29 17:10	4302
Sedimentary Geochemistry of Major Metal Hosting sub-basins within the Palaeoproterozoic Batten Fault Zone, McArthur Basin, Australia	Dana IMBROGNO	C110	2024-08-29 17:10	2024-08-29 17:25	4304
Application of explainable machine learning to geophysical data	JIACHUN YOU	C110	2024-08-29 17:25	2024-08-29 17:40	4293
African geologic formation databases with visualizations onto plate reconstructions	James G OGG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4309
China and southeast Asia geologic formation databases with visualizations onto plate reconstructions	Gabriele OGG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4310
Indian Plate and Middle East geologic formation databases with visualizations onto plate reconstructions	O'Neil MAMALLAPALLI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4311
New Permian Tethyan Paleogeographic Reconstruction and its implication to the collapse of the Late Paleozoic Ice Age	Qiang Ren	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4313
Leveraging Large Language Models for Sedimentary Environmental Interpretation: A New Approach To Addressing The Non-Uniqueness Problem In Paleogeography	Haipeng LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4314
Plate Tectonics & Paleogeography during the Last 1.5 Billion Years	Christopher Robert SCOTESE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4315
Critical depths of the vertical transition zone between modern infiltration water and fossil groundwater in China	Ying YU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4316
Heterogeneity in spatiotemporal evolution of groundwater storage in the North China Plain and its driving mechanisms	Xiaowei ZHAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4317
Web GPlates: The Next-Generation Research Platform of Paleogeographic Reconstruction	Han CHENG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4318
Provenance Evolution Across the North Australian Craton from 1.8 to 1.3 Ga: Basin Analysis and Plate Tectonic Evolution.	Morgan L. BLADES	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4319
The progress and perspective of digital intelligence paleogeographic reconstruction	MINGCAI HOU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4321
"Paleotopographic Mapping": A Tool for Creating New Paleotopographic Models	Fan SHU	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4322
Construction of a fluvial facies knowledge graph and its application in sedimentary facies identification	Lei ZHANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4323

Title	Presenter	Venue	Start	End	Page
S7 Geothermal Energy: Theory, Practice, and Global Opportunities		Session Chair: Higinia Terregrosa Morales			
[Keynote] A Global Energy Outlook: Implications for Geothermal Energy	Richard J Chuchla	C110	2024-08-26 16:00	2024-08-26 16:30	4326
Project InnerSpace's GeoMapTM: Unlocking Geothermal Potential Worldwide	Jamie BEARD	C110	2024-08-26 16:30	2024-08-26 16:45	4331
Heat extraction performance and seismic potential estimation of horizontal well doublets in enhanced geothermal systems: insights from coupled thermo-hydro-mechanical modeling	Wei JIANG	C110	2024-08-26 16:45	2024-08-26 17:00	4325
A fast approach predicting geothermal play fairways using machine learning to multidisciplinary big data-Case studies in Africa and China	Shu JIANG	C110	2024-08-26 17:00	2024-08-26 17:15	4327
Target Optimization for Hot Dry Rock Resources in the Jizhong Depression	XIAOXUE JIANG	C110	2024-08-26 17:15	2024-08-26 17:30	4328
Characterization of structurally controlled geothermal systems	Gemma Mitjanas	C110	2024-08-26 17:30	2024-08-26 17:45	4330
Physics-based Machine Learning Model for Predicting Geothermal Heat Flow in Henan Province, China	Kewen LI	C110	2024-08-26 17:45	2024-08-26 18:00	4324
Prediction of heat flow distribution in North China, based on digital geomorphic and multi-geophysical data	Chuanqing ZHU	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	4333
Integrations of geothermal exploration techniques in the Guguan geothermal potential area, Taiwan	Rou-Fei CHEN	Exhibition Hall	2024-08-26 16:00	2024-08-26 18:00	4334
S8 Deep-time Digital Earth (DDE) – Progress, Challenges and Plans for 2024-2030		Session Chair: Natarajan Ishwaran			
[Keynote] Deep-time Digital Earth: an overview of progress since 2019, and a look into the future	Michael H Stephenson	C110	2024-08-29 08:00	2024-08-29 08:30	4336
[Keynote] The Deep-time Digital Earth Program in the Evolving Global Research Data Landscape	Kerstin Annette Lehnert	C110	2024-08-29 08:30	2024-08-29 08:45	4343
Unlocking the Deep-time Earth with Open Keys: Collaboration, Platform and Research projects.	Chao LI	C110	2024-08-29 08:45	2024-08-29 09:00	4338
Data-driven Hydrogeology Research Hatched by the OneGroundwater Platform	Jianmei Cheng	C110	2024-08-29 09:00	2024-08-29 09:15	4339
DDE OneSediment: a comprehensive sedimentological and palaeogeographic database and research platform	Xiumian Hu	C110	2024-08-29 09:15	2024-08-29 09:30	4341
Building the Earth System History Machine: A Dynamic Simulation of Plate Tectonics, Paleogeography, Paleoclimate and Paleobiogeography.	Christopher Robert SCOTESE	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4345
DDE scholar report: a new open and Ai frontier and innovative reflect for solid earth	Meng WANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4346
IMMERSIVE VIRTUAL EXPERIENCE: A NEW "LOOK UP" TO THE GSSPs	Simonetta Monechi	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4347
S9 Progress and Opportunities in Deep-time Paleomagnetism		Session Chair: DDE			
[Invited] Building Stacked Relative Paleointensity Records for Chron C18: Insights into the Geodynamo Characteristics Over Extended Timescales	Yuhji YAMAMOTO	M312	2024-08-29 09:30	2024-08-29 09:45	4348
The reliability of Cretaceous redbed paleomagnetic datasets from the Tibetan Plateau	Jiahui MA	M312	2024-08-29 09:45	2024-08-29 10:00	4349
Closing the Unimos Ocean and assembling Rodinia	Nicholas SWANSON-HYSELL	M312	2024-08-29 10:00	2024-08-29 10:15	4352
Neoarchean plate mobilism: constraints from paleomagnetic results of Wyoming and Superior	Jikai Ding	M312	2024-08-29 10:15	2024-08-29 10:30	4353
Combined paleomagnetic and geochronological data from the ca. 1240 Ma mafic dikes in the North China Craton (NCC) and its implications	Jikai Ding	M312	2024-08-29 10:30	2024-08-29 10:45	4355
The Balanced Billion	Ross N MITCHELL	M312	2024-08-29 10:45	2024-08-29 11:00	4350
Analyzing the paleosecular variation of Earth's geomagnetic field 1.1 billion years ago and its implications for understanding ancient field morphology	Hanqing ZHAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4357
New paleomagnetic and geochronology data from Early Cretaceous volcanic rocks of the central Tethyan Himalaya: insights into the size of Greater India	Xianwei JIAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4358
New paleomagnetic results from the late Mesoproterozoic Luanshigou Formation of the Shennongjia Group in south China, and their paleogeographic implications	Yixuan Liu	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4360
Paleomagnetic and geochronologic results from the Zenong Group and Yeba Formation volcanic rocks in the Lhasa terrane: New insights into the closure time of the Meso-Tethyan Ocean	Tianshui YANG	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4362
Exploring rock-magnetic parameters for efficient sample preselection on the Tsunakawa–Shaw paleointensity method: a study from data of Cenozoic basalts	Hyeon-Seon AHN	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4364
New Early Permian Paleomagnetic Data from the Northern Margin of the North China Block and its Implications for Regional Climate and Biological Evolution	Qiang Ren	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4365
The rock-magnetism and natural remanent magnetization of the Ordovician sedimentary rocks in the southwest Ordos Basin (Central China)	Shuang DAI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4366
How did the Jurassic True Polar Wander meet plate motion in Asia?	Yangjun GAO	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4368
New paleomagnetic results from the late Ediacaran Dengying Formation in South China	Haiyan LI	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4370

Title	Presenter	Venue	Start	End	Page
Exploring sedimentary records of sea level and carbon cycling as independent tests of true polar wander: Case studies from the Paleoproterozoic to Cretaceous	Yu-Shu Liu	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4372
Paleomagnetic studies of the Neoproterozoic Jinchuan Ultramafic rock Unit and Paleozoic dykes inside it, revealing its affinity to North China Block since Cambrian	Ronghua Wang	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4373
A Review of True Polar Wander in the Tonian (~850-750 Ma)	Joseph MEERT	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4375
S10 Geoscience Data Standards and Knowledge Graph		Session Chair: Zhang Minghua, Young Joo LEE			
[Keynote] Standards: a challenge for the future of geosciences	Francois Robida	C110	2024-08-30 08:15	2024-08-30 08:30	4388
DataExpo: A One-Stop Dataset Service for Open Science Research in Geosciences	Bin Lu	C110	2024-08-30 08:30	2024-08-30 08:45	4378
Geoscience information metadata standard supports DDE resources Open and FAIR	Minghua ZHANG	C110	2024-08-30 08:45	2024-08-30 09:00	4381
A Geoscience Temporal Ontology Incorporating ISO Standards and Allen Temporal Relations	Shu WANG	C110	2024-08-30 09:00	2024-08-30 09:15	4383
Construction and Sharing of CGS National Geological Database	Shoutao JIAO	C110	2024-08-30 09:15	2024-08-30 09:30	4385
Progress and challenge in geoscience standards of the IUGS Deep-time Digital Earth program	Minghua ZHANG	C110	2024-08-30 09:30	2024-08-30 09:45	4376
A comprehensive knowledge base for representing version information in geologic time scale knowledge graph	Hongwei Wang	C110	2024-08-30 09:45	2024-08-30 10:00	4389
Paleobiogeographic Knowledge Graph: An Ongoing Work with Fundamental Support for Future Research	Linna ZHANG	C110	2024-08-30 10:00	2024-08-30 10:15	4390
Creating Open Standardized Global Networks of All Types of Geochemical Data from Multiple Countries, Repositories, and Researchers: The OneGeochemistry and WorldFAIR Initiatives	Kerstin Lehnert	C110	2024-08-30 10:15	2024-08-30 10:30	4391
DDE OnePetrology Database and Standard (Igneous Rocks)	Ying TONG	C110	2024-08-30 10:30	2024-08-30 10:45	4393
The Methodology, Progress and Challenges of Geoscience Knowledge Graph in International Big Science Program of Deep-Time Digital Earth	Yunqiang Zhu	C110	2024-08-30 10:45	2024-08-30 11:00	4379
Construction and application of an ontology-based domain-specific knowledge graph for petroliferous basin evaluation		C110	2024-08-30 11:15	2024-08-30 11:30	4387
Research on the standard of building database of Geophysical-Geochemical-Remote Sensing data based on data model	wei REN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4395
Study on the Crowdsourcing and Sharing System Model for Lithogeochemical and Geochronological Data	Rui YU	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4397
Knowledge Graph Schema of Mineral Deposit: The Design, Application, and Significance	Chengbin WANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4398
Joint inversion of gravity and magnetic 2-3D for the structure of hidden phosphorus deposit	xingting WANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4399
Master	YU MENG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4400
An One-Stop Application for DDE Metadata	Wei YAN	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4401
Construction and application of geophysical knowledge graph in Antarctica	Yuanyuan ZHANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4403
Geospatial-aware representation learning model for point of interest(POI) matching	Xiaoliang DAI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4405
How do Earth Sciences Contribute to Advancing the Sustainable Development Goals? A Bibliometric Analysis	Yu ZHAO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4406
Research on the method of signal-to-noise separation for aerial gamma ray spectrometry data based on curvelet transform	HUAIYUAN LI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4407
Underground spatial distribution of uranium and radium elements in Barun uranium deposit, Erlian Basin, Inner Mongolia	Nan Gan	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4409
Paleontology knowledge graph for data-driven discovery	Yiying Deng	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4410
S11 Deep-time climate change – novel insights from paleoclimate modelling and the geologic record		Session Chair: DDE			
[Invited] The development of a Mediterranean climate resulted from the rise of SE Tibet	Lin DING	M312	2024-08-29 14:30	2024-08-29 14:45	4414
Phanerozoic Paleotemperatures and CO2 Levels	Christopher Robert SCOTESE	M312	2024-08-29 14:45	2024-08-29 15:00	4412
Steep oceanic DIC δ13C depth gradient during the Hirnantian Glaciation	Shengchao Yang	M312	2024-08-29 15:00	2024-08-29 15:15	4416
Modelling the dramatic atmospheric and oceanographic changes during the end-Permian crisis	Yadong Sun	M312	2024-08-29 15:15	2024-08-29 15:30	4417
Modelling Phanerozoic Climates and Biogeochemistry	Paul VALDES	M312	2024-08-29 15:30	2024-08-29 15:45	4411
[Invited] Mass extinctions make way for metabolic makeovers: the rise of dinosaurs and the avian metabolism	Jasmina WIEMANN	M314	2024-08-28 08:00	2024-08-28 08:15	4421
Dinosaur distribution under long-term climate changes	Qi Cui	M314	2024-08-28 08:15	2024-08-28 08:30	4420
The first Cretaceous dinosaur fossil assemblage in Southwest China	Hui DAI	M314	2024-08-28 08:30	2024-08-28 08:45	4419
How important is palaeogeography in simulating the evolution of the East Asian monsoon?	Alex James Farnsworth	Exhibition Hall	2024-08-28 10:00	2024-08-28 18:00	4418
S13+S14 Encouraging Early Career Scientists' (ECS) Engagement with DDE		Session Chair: DDE			

Title	Presenter	Venue	Start	End	Page
[Keynote] Data and model-driven paleogeographic research: some recent progress	Haipeng Li	M312	2024-08-30 08:00	2024-08-30 08:15	4423
One-step Database Construction Based on Knowledge System: A Practice with the Example of DDE OnePetrology Database	DING YI	M312	2024-08-30 08:15	2024-08-30 08:30	4425
Digital geological maps on the Global Layer platform	YANG SONG	M312	2024-08-30 08:30	2024-08-30 08:45	4426
The need for Open Multidisciplinary Geodatabases in Earth Sciences: from the World 5M to Basement Geology and Water Circulation	Benjamin SAUTTER	M312	2024-08-30 08:45	2024-08-30 09:00	4427
Global Layer and Geological Map of the World at a scale 1/5M	Xingchen YANG	M312	2024-08-30 09:00	2024-08-30 09:15	4429
The Digital Transformation of Geological Data in Cambodia	KEAT LENARITH	M312	2024-08-30 09:15	2024-08-30 09:30	4422
T38 Anthropocene					
S1 Anthropocene, History and the Geosciences: contributions to contemporary debates		Session Chair: Claudine COHEN			
[Keynote] The decision in favor of the Anthropocene	Juergen RENN	M314	2024-08-29 08:00	2024-08-29 08:30	4441
The Historiography of the Earth and 'Anthropocene': Regional Geo-history and Possible Worlds in the Steno-Leibniz Process	Toshihiro YAMADA	M314	2024-08-29 08:30	2024-08-29 08:45	4436
The Anthropocene, Crawford Lake and Human-Geological Interactions	Ernst HAMM	M314	2024-08-29 08:45	2024-08-29 09:00	4439
Why the concept of the Great Acceleration is crucial to defining the Anthropocene	Francine M.G.McCarthy	M314	2024-08-29 09:00	2024-08-29 09:15	4434
Climate change revealed by the sedimentary record of the Pearl River Estuary and its implications for the Anthropocene	Jianfang HU	M314	2024-08-29 09:15	2024-08-29 09:30	4435
Anthropocene scepticism?	Michael WAGREICH	M314	2024-08-29 10:00	2024-08-29 10:15	4432
Georjuridicality: law, forensics and the Anthropocene	Alexander DAMIANOS	M314	2024-08-29 10:15	2024-08-29 10:30	4430
Soils and Sciences in the Anthropocene: Historiographic Considerations	Robert M. BRAIN	M314	2024-08-29 10:30	2024-08-29 10:45	4431
EARLY-MODERN VISIONS OF THE « EARTH SYSTEM » LEIBNIZ, TELLIAMED, HUTTON	Claudine COHEN	M314	2024-08-29 10:45	2024-08-29 11:00	4437
S2 UNESCO IGCP 732 and the Stratigraphy of the Anthropocene		Session Chair: Michael WAGREICH			
[Keynote]Evolution of stratigraphy in the Anthropocene Across Africa	Lydia A. OLAKA	M314	2024-08-29 14:30	2024-08-29 15:00	4449
Introduction to UNESCO IGCP 732 LANGUAGE of the Anthropocene and the International Geoscience Program	Veronika Koukal	M314	2024-08-29 15:00	2024-08-29 15:15	4443
Radioactive fallout defining the base of the proposed Anthropocene Series in the varved sediments of Crawford Lake	Francine M.G.McCarthy	M314	2024-08-29 15:15	2024-08-29 15:30	4445
Impacts of plastic-rich sediments on the geological processes: A numerical investigation	Eun Young Lee	M314	2024-08-29 15:30	2024-08-29 15:45	4442
Progress on the Anthropocene study in China	Luyuan ZHANG	M314	2024-08-29 16:00	2024-08-29 16:15	4450
Does anthropogenic interference disturb sedimentation in closed lakes? Evidence from the Kalar Kahar Lake, Potwar Plateau, Pakistan	MEHWISH BIBI	M314	2024-08-29 16:15	2024-08-29 16:30	4447
Anthropocene 129I record in the Yellow Sea sediments and its indication for river-delivered radioactive pollution to marginal seas	Yanyun WANG	M314	2024-08-29 16:30	2024-08-29 16:45	4452
Carbon Stock and Organic Matter Changes Three Decades After Mangrove Tree Planting Efforts in Kalibo (Aklan), Philippines	Caroline Marie Brinas Jaraula	M314	2024-08-29 16:45	2024-08-29 17:00	4454
A Marine Geological Park Concept for volcano-tectonic and Hydrothermally Induced Submarine Groundwater Discharge Features and Their Implications to Coral Reefs in Mabini, Batangas	Caroline Marie Brinas Jaraula	M314	2024-08-29 17:00	2024-08-29 17:15	4453
Anthropogenic stratigraphic signals downstream a metropolis: Extracting Vienna's signature from Danube river plain archives (Austria)	Diana HATZENBÜHLER	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4455
The geological usefulness of a defined chronostratigraphic Anthropocene for urban deposits of Karlsplatz, Vienna (Austria)	Michael WAGREICH	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4457
Anthropogenic sediments in the urban setting of Karlsplatz, Vienna (Austria)	Maria MESZAR	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4458
Geochemical evaluation of anthropogenic depositions in Brazil: case study in Rondonópolis-Mato Grosso	ÉRIKA CRISTINA NESTA SILVA	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4460
Introduction and first results from FT-IR microplastics identification in natural sediments	Veronika Koukal	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4462
Anthropogenic activities tamper with Laguna Lake's (Philippines) 20th century record of the Pacific Decadal Oscillation	Caroline Marie Jaraula	Exhibition Hall	2024-08-29 10:00	2024-08-29 18:00	4464
S3+S4 From the Holocene to Anthropocene - reading the geological and archaeological records of interplay between the nature and human		Session Chair: Scientific Program Committee			
[Keynote] Time to explore more of the Anthropocene	Buhm Soon PARK	M314	2024-08-30 08:00	2024-08-30 08:15	4481
Stratigraphic signals of human-environment interactions on the Meghalaya Plateau: Implications for defining the Anthropocene boundary	Pawel PROKOP	M314	2024-08-30 08:15	2024-08-30 08:30	4471
Deciphering Social-Ecological Transitions in the Anthropocene: An Evolutionary Framework Reveals Dynamics and Decoupling in China's Yangtze River Delta	KE ZHANG	M314	2024-08-30 08:30	2024-08-30 08:45	4478
Anthropocenic significance of waste strata	Wook-Hyun NAHM	M314	2024-08-30 08:45	2024-08-30 09:00	4480
Lithostratigraphic Study on Human-made strata in Kirishima City, Kagoshima Prefecture, Japan	Hiroshi TAKASHIMA	M314	2024-08-30 09:00	2024-08-30 09:15	4473

Title	Presenter	Venue	Start	End	Page
Geomorphic Succession of an Abandoned Paddy Field in Mountain Area	Junho LEE	M314	2024-08-30 09:30	2024-08-30 09:45	4468
Vegetation and land-use changes during last two millennia in the Baspa valley, Kinnaur, Western Himalaya	NIDHI TOMAR	M314	2024-08-30 09:45	2024-08-30 10:00	4475
Anthropogenic large-scale dune remobilization in medieval–early modern Central Europe, evidenced by multi-proxy data and radiocarbon dating	Krzysztof Ninard	M314	2024-08-30 10:00	2024-08-30 10:15	4465
Anthropogenic landscape changes with planting pines on coastal dune fields	Kwang Hee CHOI	M314	2024-08-30 10:15	2024-08-30 10:30	4467
Anthropogenic beachrock analogues and their significance for the Anthropocene stratigraphy	Agnieszka GAŁUSZKA	M314	2024-08-30 10:30	2024-08-30 10:45	4479
Interplay of climate forcing and human impact during the Holocene: a case study from an inner marine basin in the Mediterranean region	Gabriele NICCOLINI	M314	2024-08-30 10:45	2024-08-30 11:00	4469
Anthropogenic changes in river landforms and application of nature-based solutions in South Korea	Dahae GO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4482
How palaeontological signatures of the Anthropocene are stratigraphically unique.	Colin WATERS	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4483
Mapping of submerged landforms by dam construction using historical aerial photos	Jae Hyun HWANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4485
The lagoon of Venice (Italy) in antiquity: insights into settlement dynamics, adaptive behaviours, and palaeoenvironmental reconstructions	Adele BERTINI	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4486
Radiogenic Isotopes, Geochemistry, Petrography of Raw Materials: A Case of Archaeological Ceramic Circulation in the Atacama Desert (Iluga Túmulos, Tarapacá, Northern Chile)	Camila RIERA-SOTO	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4488
The duration of the Anthropocene epoch	Martin J. Head	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4492
Tracing Anthropocene signatures: Sediment core analysis along the west coast of Korea, Yellow Sea	Tae Soo CHANG	Exhibition Hall	2024-08-30 10:00	2024-08-30 16:00	4490
T39 Geoethics and Societal Relevance of Geosciences					
S1+S2 GEOETHICS AT THE HEART OF ALL GEOSCIENCE: SERVING THE PUBLIC GOOD		Session Chair: Scientific Program Committee			
Bridging Continents: Building Environmental Awareness and Sustainability with geoscience communication through EuroGeoSurveys' PanAfGeo and GSEU projects	Patrick Wall	C205	2024-08-27 08:00	2024-08-27 08:15	4503
Regulating Geoscience in a Diverse Federation of Independent Regulators – The Canadian Example	MARK PRIDDLE	C205	2024-08-27 08:15	2024-08-27 08:30	4513
Bias in accepting diversity of interpretation in Earth Sciences – historical perspectives and modern challenges	Rob BUTLER	C205	2024-08-27 08:30	2024-08-27 08:45	4514
Responsible Earth/Geosciences and Planetary-Scale Anthropogenic Change	Giuseppe Di Capua	C205	2024-08-27 08:45	2024-08-27 09:00	4501
Geological and Natural Inheritance of Uzbekistan: Research and Conservation of Wealth	Ziyoda Kamunalovna AKHMEDOVA	C205	2024-08-27 09:00	2024-08-27 09:15	4511
Geotourism and geoethics as support for rural development in the Sundarbans Wetlands - a Ramsar site of West Bengal, India	Sayani KHAN	C205	2024-08-27 09:15	2024-08-27 09:30	4507
Ethical Solutions: Climate Intervention Research, Experimentation, and Potential Deployment	Mark SHIMAMOTO	C205	2024-08-27 09:45	2024-08-27 10:00	4505
Operational ethics for researching geohazards	ILAN KELMAN	C205	2024-08-27 10:00	2024-08-27 10:15	4496
Towards Integrating Indigeneity and Geoethical Practice – Case Studies from Aotearoa New Zealand	Matthew W. HUGHES	C205	2024-08-27 10:15	2024-08-27 10:30	4494
An infrastructure designed for the research and global promotion of geoethics	Giuseppe Di Capua	C205	2024-08-27 10:30	2024-08-27 10:45	4499
Geoscience Across Borders: Leveraging Geoscience Diplomacy for International Cooperation.	Munira Raji	C205	2024-08-27 10:45	2024-08-27 11:00	4497
Ethical Frontiers and Legal Landscapes: The ethics of geoengineering the Moon, Mars and other celestial bodies	Dov GREENBAUM	C205	2024-08-27 11:00	2024-08-27 11:15	4506
Synthetic Seas: Ethical, Legal, and Social Dimensions of Genetically Engineered Phytoplankton for Climate Mitigation Contrast with Ocean Iron Fertilization	Dov GREENBAUM	C205	2024-08-27 11:15	2024-08-27 11:30	4509
Geological Surveys, Mining Industry Cycle and Government management! Sustainable development or conflict in national interests!	shirin safavi	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4516
Fossils, museums and ethics – from site based conservation to institutional acquisition	Kevin Page	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4517
Science of Geoethics: Challenges and Opportunities	Devesh WALIA VIILLACORTA CHAMBI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4519
T40 History of Geological Sciences					
S1 History of women in the Geological Sciences: trailblazers, leaders and those in the shadows		Session Chair: Scientific Program Committee			

Title	Presenter	Venue	Start	End	Page
[Keynote] Mexican Women in the Paleontology and Oil Industries	Lucero MORELOS-RODRIGUEZ	M314	2024-08-26 16:00	2024-08-26 16:15	4531
Etheldred Benett (1776-1845) and the Unacknowledged Contributions of an Early English Woman Geologist	Renee M CLARY	M314	2024-08-26 16:15	2024-08-26 16:30	4522
Anna Hietanen (1909–1994) – from Finland to the world	Elina LEHTONEN	M314	2024-08-26 16:30	2024-08-26 16:45	4529
Geological Scenes from Two Marriages – Mary Elizabeth Lyell and Emma Darwin Compared	Martina KÖLBL-EBERT	M314	2024-08-26 16:45	2024-08-26 17:00	4525
Marie Stopes (1880-1958) and Kono Yasui (1880-1971)- the beginning of paleobotany in Japan	Michiko dvan Yajima	M314	2024-08-26 17:00	2024-08-26 17:15	4523
Martha Cornelius-Furlani (1886-1974) and Adelheid Kofler (1889-1985) - the First Female Geoscientis at the University of Vienna	Margret HAMILTON	M314	2024-08-26 17:15	2024-08-26 17:30	4520
Women and diamonds	Leonid R. KOLBANTSEV	M314	2024-08-26 17:30	2024-08-26 17:45	4526
Mrs A. H. Foord and G. M. Woodward: 19th century translators and illustrators of cephalopod studies	Catherine (Kathleen) HISTON	M314	2024-08-26 17:45	2024-08-26 18:00	4528
S2 History of Geoscientific Travels in Asia and Beyond		Session Chair: Scientific Program Committee			
[Keynote] Takla Makan, Pamirs, Karakorams, Indogangetic Plain, Singhala and Java: The Buddhist topography of Faxian (Fa-Hien), at the beginning of the 5th Century CE.	Sharad MASTER	M314	2024-08-27 14:30	2024-08-27 14:45	4532
Ennin's Pilgrimage Travel in China: Japanese Buddhist Geo-consciousness in the Ninth Century	Toshihiro YAMADA	M314	2024-08-27 14:45	2024-08-27 15:00	4547
Drainage work at the Clausthal mine in the Harz region in the 17th century: Achievements of the Japanese Peter Hartzing（1637-1680）	Takeshi Ozawa	M314	2024-08-27 15:00	2024-08-27 15:15	4537
The first geophysical studies, and descriptions of mineral deposits, in Thailand: The French Jesuits under Guy Tachard, and Simon de la Lubère, at the Siamese Court in 1687 and 1689.	Sharad MASTER	M314	2024-08-27 15:15	2024-08-27 15:30	4534
Professional Travelers -– Considering Expanding Process of Professionalism in the Nineteenth-Century United States --	Tomomi NAKAGAWA	M314	2024-08-27 15:30	2024-08-27 15:45	4545
Prussian geographer J. J. Rein travelled to Japan in 1873-76 and introduced Japan to the world	Michiko dvan Yajima	M314	2024-08-27 15:45	2024-08-27 16:00	4544
Crossing the Urals: A Glimpse into Asia in 1841	John DIEMER	M314	2024-08-27 16:15	2024-08-27 16:30	4536
Charles Gould: Travels in Asia	Carol Anne Bacon	M314	2024-08-27 16:30	2024-08-27 16:45	4538
BRONISŁAW GRĄBCZEWSKI AND LEON BARSZCZEWSKI, THEIR TRAVELS IN CENTRAL ASIA IN XIX CENTURY AND CONTRIBUTIONS IN GEOLOGY	Piotr KRZYWIEC	M314	2024-08-27 16:45	2024-08-27 17:00	4548
The Early History of Graptolites Discovery in Asia	Muhammad Aqqid Saparin	M314	2024-08-27 17:00	2024-08-27 17:15	4542
Geological travels and mapping in the Himalayan region between the 19th and the 20th century	Ezio VACCARI	M314	2024-08-27 17:15	2024-08-27 17:30	4540
Multifaceted Nature of Japanese Geological Explorations amid Japanese Imperial Expansion to China in the early 20th century	Shigeo KATO	M314	2024-08-27 17:30	2024-08-27 17:45	4550
Western scholars' geoscientific travels in China during the late 19th and early 20th centuries	Chengsheng SUN	M314	2024-08-27 17:45	2024-08-27 18:00	4552
Legacy etched in Stone: Field Inscriptions of BGS Geologist E. Vredenburg Enduring for 125 Years in the Chagai Desert, Pakistan	Mukhtiar GHANI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4553
S3+S4 General Contributions to the History of Geological Sciences		Session Chair: Scientific Program Committee			
[Keynote] Exposing Earth Sciences History: challenges and perspectives (invited Keynote)	Maddalena NAPOLITANI	M314	2024-08-27 08:00	2024-08-27 08:15	4557
Geological and Hydrological Knowledge of the Aztecs	Sharon LOCKE	M314	2024-08-27 08:15	2024-08-27 08:30	4562
The "Treatises on How to Recognise Gems" of Al-Biruni (11th century) and the development of mineralogy in The Muslim world.	khallaf EL GHALBI	M314	2024-08-27 08:30	2024-08-27 08:45	4555
Image Builders between Mineralogical Knowledge, Possession and Perception in the 18th Century: Catalogues, Collections and Credibility	Marianne Dr. KLEMUN	M314	2024-08-27 08:45	2024-08-27 09:00	4556
James Dwight Dana and his geological excursions in New South Wales, 1839-40	Wolf Mayer	M314	2024-08-27 09:00	2024-08-27 09:15	4559
The heydays of geological research in Finland – Storylines from the museum collections	Jaana HALLA	M314	2024-08-27 09:15	2024-08-27 09:30	4561
The Geological Commission of the Shevchenko Scientific Society: Institutions, Personalities, Publications	Ihor BUBNIAK (BUBNYAK)	M314	2024-08-27 09:30	2024-08-27 09:45	4558
Learning the Soviet Union and Earth Sciences of China: An investigation centered on Specialty Settings of Geography in Peking University In the 1950s	Chao LIU	M314	2024-08-27 09:45	2024-08-27 10:00	4560
Geological maps throughout the hundred years of the Czech Geological Survey (1919–2024)	Vladimir ZACEK	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4563
From Mines to Strata: The Spatial Sciences of the Earth in Britain in the Long Eighteenth Century	Joshua HILLMAN	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4564
150 years of the Italian Geological Survey and the new database of national georesources	Mauro LUCARINI	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4565

Title	Presenter	Venue	Start	End	Page
Solving the Urgent Situation: Analysis of Local Mineral Resource Survey Institutions during the period of the Republic of China	weiwei HU	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4567
The collection of geological wall maps and their importance in teaching	Maria MESZAR	Exhibition Hall	2024-08-27 10:00	2024-08-27 18:00	4568
T41 Mathematical and Computational Methods for the Geosciences					
S1 AI-driven mineral prospectivity mapping		Session Chair: Scientific Program Committee			
Mapping geology using textural feature extraction and unsupervised community detection models on airborne geophysics	Katie L Silversides	M217	2024-08-29 09:30	2024-08-29 09:45	4578
Lithological mapping based on multi-source geoscience data and deep learning algorithms	Ziye WANG	M217	2024-08-29 09:45	2024-08-29 10:00	4575
Geological data mining in mineral resources national survey database	Zhao TING	M217	2024-08-29 10:00	2024-08-29 10:15	4590
Decision-tree models used to detect mineral deposits in Uzbekistan by analyzing ring, lineament structures, and faults	Oksana Gennadevna TSAY	M217	2024-08-29 10:15	2024-08-29 10:30	4573
A hybrid deep learning model of superpixel graph convolutional network and 1DCNN for geochemical anomalies identification	Ying Xu	M217	2024-08-29 10:30	2024-08-29 10:45	4572
Dual branch convolutional neural network and its post-hoc interpretability for mapping mineral prospectivity	Fanfan YANG	M217	2024-08-29 10:45	2024-08-29 11:00	4571
Predictive Mapping of Exploration Targets with Interpretable Machine Learning and Moderated Prediction Values	Emmanuel John CARRANZA	M217	2024-08-29 14:30	2024-08-29 14:45	4570
Automated boundary detection in drillhole data by leveraging AI and machine learning algorithms	Hamid ZEKRI	M217	2024-08-29 14:45	2024-08-29 15:00	4588
A semi-supervised learning method applied in designing optimal infill drillings, a case study at the Dalli porphyry Cu-Au deposit in Iran	Hooshang Asadi	M217	2024-08-29 15:00	2024-08-29 15:15	4576
Detailed mineral, grade, and potential mapping by applying deep neural network-based methods to remote sensing, drilling, and seafloor data	Katsuaki KOIKE	M217	2024-08-29 15:15	2024-08-29 15:30	4582
Neural kriging-based specification and 3D modeling of concentrated zones of rare earth elements in deep-sea mud layers	Vitor Ribeiro de Sa	M217	2024-08-29 15:30	2024-08-29 15:45	4580
Research on Key technology of 3D ore-forming field simulation of Caixiashan Pb-Zn deposit, Eastern Tianshan area, Xinjiang autonomous Region	Li SUN	M217	2024-08-29 16:15	2024-08-29 16:30	4591

[Plenary] VANISHED OCEAN: How Tethys Re-shaped the World

Dorrik STOW[1]*, Heriot- Watt University (D.Stow@hw.ac.uk)

Abstract

A hundred million years ago, a mighty ocean dominated the equatorial world. Its vast waters bore witness to many of most dramatic episodes in the story of our planet. It played host to a plethora of fascinating organisms, saw great mass extinctions and then nurtured the ensuing rebirth of new life forms. It endured its own secret drama of submarine quakes and powerful currents, at one point quaking under evening skies lit by the outpourings of a super-volcano that exploded along its northern margin. For long ages, its quiet central gyres were more desolate and empty than anything seen in today's world. But then, five and a half million years ago, it quite simply disappeared. It was called the Tethys Ocean and this is a kaleidoscope of images from that lost world, pieced together from myriad clues, which are now scattered through the rocks that stretch from Morocco to China, from the depths of the Caspian Sea to the highest Himalayan peaks. Though imperfect and incomplete, the record is varied and captivating, telling something of the assembly and splintering of continents, the rise and fall of mountain ranges, the changing ocean currents and their link to Earth’s climate, the remarkable story of oil and gas, and other deep-ocean treasures. Such changes in the land and ocean have been strongly instrumental in shaping the colourful pageant of life through the past 250 million years of Earth history, and in painting the template
for the oceans of today.

[Plenary] THE NETWORK TOPOLOGY OF FRACTURES, TECTONIC PLATES AND GEOLOGICAL MAPS

David SANDERSON[1]*, University of Southampton (d.j.sanderson@soton.ac.uk)

Abstract

Many geological features are encountered and represented as networks on a surface, e.g. a map, cross-section or field sketch of an exposure surface. A network of fracture or stratigraphic traces can be represented by branches (B) that end or intersect at nodes (N) and sub-divide the surface into regions (R) - the node-branch model of Sanderson and Nixon (2015). Whereas geometry is used to describe the location, length, shape, and orientation of elements within the network, topology is used to describe the relationships between these elements. Thus, topology compliments geometry and enhances geological mapping. A range of tectonic and geological examples will be discussed to illustrate both the added-value and efficiency gained by including topology. Graph theory can be used to analyse a node-branch representation of networks (Sanderson et al. 2019), which usually form simple, planar graphs with well-established, mathematical properties. The description is straightforward and intuitive, usually forming a part of the initial mapping procedures and easily adapted to remotely sensed data. The mathematics is simple, requiring little more than counting the nodes and branches. To date, most applications in tectonics have been applied to fault and fracture networks, usually at a small-scale. These will be extended to consider superposed networks, and methods that allow extraction of kinematic and sequence information from maps. The scale can be extended to the plate tectonic system, which represents a good example of a simple graph on a sphere that obeys Euler's formula that $|N|-|B|+|R| = 2$, one of the simplest and most important formula in mathematics. A geological map can be considered as a network made up of traces of stratigraphic boundaries and superposed tectonic elements, mainly faults. GIS software can make use of topology in constructing geological maps, but little use is made of topological parameters, axioms, and proofs in their analysis. The potential of topology to revolutionise interpretation of geological maps will be briefly discussed.

[Plenary] The future of geosciences through the lens of geoethics

Silvia PEPPOLONI[1]*, Italian Institute of Geophysics and Volcanology (silvia.peppoloni@ingv.it)

Abstract

The increasing human impact on the Earth system is leading to an unprecedented ecological crisis at a planetary scale, recognized by science worldwide. Global warming, climate change, pollution, biodiversity loss, represent together a multifaceted challenge, a global "polycrisis," intertwining social, economic, political, and cultural factors with environmental concerns, and outlining a complex landscape for action. Geosciences emerge as vital disciplines for understanding and managing the intricate interactions between humanity and the Earth system, offering pathways and providing essential insights to address this polycrisis. Through informing
decision-making processes and guiding geo-environmental education across various levels, geosciences empower individuals to engage in discussions, influence outcomes, and implement solutions to socio-environmental issues on local, regional, national, and global scales. However, the effectiveness of geosciences in addressing societal challenges depends on geoscientists' awareness of the ethical, social, and cultural implications of their work. Acknowledging the historical contributions of geoscientists to unsustainable and contestable practices in the past is the first step to gain public trust, advocate for knowledge-based societies, and urge governments to adopt measures for mitigating climate change, and adapting to environmental shifts. Geoscientists possess the indispensable knowledge and the right intellectual and material tools to comprehend and manage Earth's processes. They know the meaning of concepts, such as planetary boundaries, tipping points, carrying capacity of ecological systems, that are essential to address the polycrisis and to shift the way in which human communities manage their land, resources, and natural heritage, even going so far as to influence common perceptions of the natural world. For these reasons, they have the ethical duty to actively engage as agents of social change. By transparently sharing knowledge within the scientific community and effectively and
properly communicating findings to the public, geoscientists fulfill their responsibility to guide political decisions and inform and educate society, contributing to the construction of a more ecologically sustainable and just world. At the core of this endeavor lies geoethics, emphasizing the ethical responsibility of geoscientists towards themselves, colleagues, society in all its components, including future generations, and the Earth system. Geoethics guides geoscientists in navigating the complex socio-ecological landscape of our time, by urging them to respect scientific rigor and pursue the public good in their work. Geoscientists are called upon to address particularly delicate issues which concern the responsible use of mineral resources, water and energy, the relationship with decision-makers and various stakeholders in the defense against natural risks, the application of geoscientific knowledge in sustainable management of the territory, in the pursuit of citizens' health, in the protection of the biosphere. Furthermore, geoscientists should ponder and collaborate to address other sensitive issues, such as deep-sea mining, the use of geoengineering, and the applications of artificial intelligence. The geoethical

perspective radically reshapes the ethical, social, and cultural meaning of the geosciences, by redefining their objectives towards the pursuit of well-being while respecting ecosystems.

[Plenary] Unveiling Active Fault Zone Dynamics: Harnessing Emerging Fiber Optic Sensing Technology

Kuo-Fong MA[1]*, Institute of Earth Sciences, Academia Sinica, Taiwan (fong@earth.sinica.edu.tw)

Abstract

The opportunity to observe fault zone behavior at depth with high spatial resolution is rare, and identifying the fault zone itself poses a significant challenge. The MiDAS (Milun-fault Drilling and All-inclusive Sensing) project in Taiwan recently has successfully overcome the challenge of observing fault zone behavior at depth with high spatial resolution. By retrieving the fault core associated with the Milun fault zone, visible in geophysical logs displaying low velocity and resistivity, and utilizing Optical Fiber Sensing techniques, the project effectively maps and analyzes fault behavior. The Milun fault, known for frequent slip events and generating significant earthquakes, namely the 2018 M6.4, and 1951 M7.1 earthquakes, was drilled and cored between 2021 and 2022, deploying a 3D multi-cross-fault fiber array. This array included a down-hole loop at a depth of 700m (Hole-A) crossing the fault, a surface array using commercial fiber across the fault rupture zone, and a 500m fiber downhole loop (Hole-B) at the Footwall site. The combination of high-resolution data from distributed acoustic sensing (DAS) and retrieved core samples, alongside geophysical logs, facilitates a detailed characterization of the fault structure. Within the Milun fault zone, a 20m thick fault core comprising grey and black gouge was uncovered. This fault gouge displays a unique seismic feature, consistently amplifying strain records from DAS with a ratio of approximately 2.5-3 for different event types, when compared to deeper channels consisting of consolidated rock material. Despite the narrowness of the fault gouge, its significant material contrast contributes to the observed strain amplification. These findings enhance our understanding of fault zone dynamics, particularly in terms of remote earthquake triggering and near-fault ground movements. Similar features were noted at the surface, with a wider rupture zone of about 200m evident in DAS data, supported by geophones crossing the surface rupture of the 2018 Hualien earthquake. As we delve into depth, downhole optical fiber and cores reveal a high-resolution asymmetric feature of this active fault. Moreover, borehole DAS recordings from the M7.0 Chishang earthquake on September 18, 2022, indicate static-strain changes throughout the depth, potentially aiding in the mapping of a 3D strain-field related to significant earthquakes. The direct exploration of the fault zone through this emerging high-resolution technology is a promising development that holds potential for gaining innovative insights into fault zone dynamics.

[Plenary] The role of Medical Geology in achieving the UN SDGs in Africa

Hassina MOURI[1]*, University of Johannesburg, Republic of South Africa (shmouri@uj.ac.za)

Abstract

The African continent is facing serious and continuous interlinked geo-environmental and health challenges affecting the socio-economic development of the continent.

The continent is known for its long and complex geological history and volution, geohazards including landslide, frequent earthquakes and volcanic eruptions in tectonically active regions. Furthermore, water toxicity due to its interaction with rocks and soils, and air pollution due to dust storms especially in dry parts of the continent are amongst the most common issues encountered on the continent. Drought and flood, which are also frequent in several parts of the continent, impact severely on the food crops uptake of essential elements released to the soils by weathering processes of rocks, forming a serious threat to food security. Moreover, the continent is known for its widespread, often uncontrolled mining operations and oil exploitation, which enhance the release of chemical elements and inhalable nanoparticles of minerals into the environment. Although some chemical elements such as Ca, Mg, Fe, I, F and Li are essential for our well-being, their deficiency or excess in soils, water or food as well as the presence of toxic elements such as As, Pb, Cd, Hg, Tl, U and the decay products of the latter can be detrimental to health.

From a health point of view, according to the WHO reports, the African continent is known for the high mortality rate due to the non-communicable diseases (NCDs) such as cardiovascular, chronic respiratory tract diseases and cancer. These diseases account for over 50% of deaths in some African countries. However, the primary causes of such diseases and mortality in general remain unclear in many cases and attention is mostly given to their risk factors and treatment. It is worth noting that some of the most common NCDs on the continent such as thyroid disorder, asthma and fluorosis, do not necessary cause death, but prohibit patients from working, enhancing poverty especially in rural areas, hence creating social inequalities, and affecting economic development of the continent in general.

In order to ascertain the geo-environmental causes of some of the common NCDs on the continent, it is crucial to integrate Earth Science with Public Health through Medical Geology, a field of science that deals with the impacts (positive or negative) of the geo-environment (including processes and materials) on the health of humans, animals and the ecosystems in general. This field of science is based on multi, cross- and inter-disciplinary approaches bringing together experts from various fields of science. Understanding the geological history and environment, will help provide insight into natural hazards that can (directly or indirectly) affect our health and ecosystems in general. This understanding can mitigate impacts, prevent widespread and serious health problems, which impact the socio-economic development of the continent, and save lives in a longer term.

The development of the field of Medical Geology in Africa is proved to be necessary in addressing several United Nations Sustainable Development Goals (SDGs) through partnership

[Plenary] Order in the rocks: A global language for the stratigraphy of 4.6 billion years of Earth history

David A.T. HARPER[1]*, Durham University (david.harper@durham.ac.uk)

Abstract

Stratigraphy is the oldest of the geological disciplines; its roots can be traced back to the Italian Renaissance and firmly established by the paradigm shifts of Nicolaus Steno (Superposition), Giovanni Arduino (Order), William Smith (Correlation using Fossils) and others. 19th century savants established the concepts of evolution, mass extinctions and palaeodiversity with reference to the definition and use of geological systems, series, stages and zones in terms of loosely-defined unit stratotypes. During the past 50 years, however, the concept of the Global Boundary Stratotype Section and Point (GSSP) has superseded that of the unit stratotype for the Phanerozoic. Each global chronostratigraphic unit, i.e., systems, series and stages, has a defined base marked by a ‘Golden Spike’. Almost 80% of global stages are now robustly defined in this way. This substantially increases the prospect of tuning the passage of Phanerozoic time using cyclostratigraphy and radioisotopes, together with software programs such as Stratobayes which aligns stratigraphic sections, opening new windows on the rates of biological and geological processes in deep time. The majority of Precambrian units are defined in terms of numerical ages, Global Standard Stratigraphic Ages (GSSAs), in the lack of criteria such as fossils and nonbiologic proxies to correlate them. There is, however, a real prospect that the bases of many Precambrian units can also be related to rock, in a manner similar to a GSSP.

[Plenary] 1100 years of large earthquakes in the southern San Andreas fault system: The effects of lake loading on local and regional seismicity on a fast-slipping plate boundary

Thomas ROCKWELL[1]*, SDSU (trockwell@mail.sdsu.edu)

Abstract

Paleoseismic data from several dozen paleoseismic sites in the southern San Andreas fault system (SSAF) allows for sequencing of the past 1100 years of large (M6.5+) earthquakes for the southern 200 km of the main plate boundary fault system. The SSAF lies within the larger Salton Trough, which has periodically filled and desiccated over the past millennium with a large lake (236 km3), known as ancient Lake Cahuilla. Here, we show that Lake Cahuilla has filled six times in the past 1100 years and provides time-correlative stratigraphy across many of the faults in the southern San Andreas system. At least five generalizations are clear from the paleoseismic and lake record: 1) M7 and larger earthquakes account for most of the moment release in the southern SSAF over the past 1100 years; 2) large earthquakes along the southernmost “Coachella” section of the SSAF were modulated by filling of Lake Cahuilla, with 6 of the past 7 earthquakes occurring during the six high lake stands; 3) seismic production on the southernmost San Andreas, Superstition Mountain and Imperial faults, all within the footprint of Lake Cahuilla, increased in the few hundred years after an extended dry period when the basin once again filled with water, presumably due to a change in fault strength from increased pore pressure; 4) large earthquakes on individual faults are quasi-periodic but display a relatively high coefficient of variation in recurrence time, similar to most long California records; and 5) moment release has spatially and temporally varied during the past 1100 years but within potentially predictable bounds. Together, the record suggests that the southern San Andreas fault is late in the cycle but not necessarily “overdue” as commonly reported in the media, and that a systems-level approach may be more accurate in long term earthquake forecasting than estimates made from individual faults.

[Plenary] Journey to the center of the Earth: a modest revisit

Yongjae LEE[1]*, Yonsei University (yongjaelee@yonsei.ac.kr)

Abstract

Since the fictional journey by Jules Verne in 1864, more than 100,000 non-fictional articles have been published to follow the journey to the center of the Earth. Instead of deciphering the Runic manuscript to set the passage for the journey, seismologists constructed their own maps of the Earth's interior, on which geochemists were able to color resident minerals. While the team of professor Liedenbrock embarked their epic journey through a volcano in Iceland, modern mineral physicists subject minerals to the conditions expected in the Earth's interior. As the protagonists in the novel could not complete their journey to the very center of the Earth, the scientific journey deep into our planet still awaits much more to be discovered.

In this talk, I will showcase what has been added through our own scientific journey to the Earth's interior. We set water, one of the most important volatile species on the Earth's surface, as the supporting actor in our journey. We used diamond anvils as a vehicle to have water meet minerals under the conditions expected deep inside the Earth and irradiated synchrotron X-rays to watch their interactions. As the fictional team found a subterranean river during their journey, we observed how much more water can be added into mineral carriers during subduction processes (1), how deep they can be delivered by transferring the carriers (2), and what would happen when they reach the destination at the core-mantle boundary (3). Deep past in time, the role for water in the Earth's evolution could have been quite different as depicted in the novel by a subterranean ocean with lightening clouds. By simulating the interaction conditions in the early magma ocean using the brightest and fastest X-ray light, we found how water could have played to nurture the conditions required for the origin of life on the Earth (4).

[Plenary] Anatomy of the solar system oldest rocks, Ca-Al-rich inclusions

Hisayoshi YURIMOTO[1]*, Hokkaido University (yuri@ep.sci.hokudai.ac.jp)

Abstract

Meteorites called chondrites are fragments of planetesimals that formed in the Solar System. Chondrites contain Ca-Al-rich inclusions (CAIs), which are known to be the oldest rocks formed in the Solar System. The bulk compositions suggest that the CAIs were formed by materials condensed in hot solar compositional gas. However, significant mass-independent isotopic variations have been observed among the CAIs. When the isotopic and elemental distributions of the CAIs were anatomized at sub-micrometer resolution, the isotopes and elements were heterogeneously distributed between minerals as well as within a mineral. Their distributions do not appear to correlate clearly with each other. Recently, comprehensive analyses based on crystal growth studies have been applied to the CAIs. The results show that the CAIs continued to form in a hot region of the protoplanetary disk during the first 0.5 million years of the solar system formation, based on the distributions of a short-lived nucleus Al-26. On the other hand, the formation timescales of individual CAIs were much shorter, completed within a several weeks. Kinetic experiments in the laboratory simulating the protoplanetary environment show that pressure and temperature were fluctuated drastically during each CAI formation. Especially, the pressure fluctuations reached as high as three orders of magnitude. In addition, the isotopic composition of the protoplanetary disk gas changed significantly, while the elemental composition remained almost unchanged. These new anatomical results from CAIs suggest that new and unknown violent astrophysical phenomena occurred around the proto-sun.
In this talk, I will show how to anatomize the CAIs using combinations of isotope microscopy, secondary ion mass spectrometry (SIMS), electron microscopy, electron backscatter diffraction (EBSD), and X-ray mapping, and discuss the physicochemical conditions and the time evolution of the CAI formation region in the protoplanetary disk summarized above based on the anatomical results. This anatomy would also be useful for geochemical studies of rocks.

[Plenary] Metamorphosis of Magmas in Planetary Interiors

Sung Keun LEE[1]*, Seoul National University (sungklee@snu.ac.kr)

Abstract

From molten silicates comprising the deep Hadean silicate magma ocean in early Earth to complex amorphous oxides on the surfaces of fault planes during co-seismic slip, non-crystalline oxides in earth and planetary surfaces and interiors have played essential roles in chemical and physical evolution of earth and rocky planets. Despite importance, deciphering the detailed nature of these non-crystalline silicate melts and magmas remains one of the challenging problems in earth and planetary sciences. In this talk, the recent advances and experimental efforts to reveal the properties and structures of silicate magmas are summarized. In near surface environments, we establish a new frictional melting model involving both equilibrium (controlled by particle size and composition) and metastable melting, providing insights into fault-weakening and the mechanism for large earthquakes (Lee et al. Nature Geoscience 10, 436, 2017). In upper mantle, entanglement of the melt network in basaltic melts at high pressure increases the configurational entropy. We explain how the configurational entropy can be used as a tool to explain the anomalous behavior of melts under compression (Lee et al. PNAS 117, 22938, 2020). When compressed above multi-megabar pressures, silicate magmas undergo structural evolution that are not observed at ambient pressures and substantially differ from those in the crystalline silicates. Particularly, the melt densification is accompanied with the prevalence of triply and quadruply coordinated oxygens above multi-megabar pressures. The extreme densification paths with compressed oxygens may account for anomalous negative buoyance of the complex partial melts in the deeper part of the mantle and those in the super-Earth bodies (Lee et al. PRL 123, 235701, 2019; Kim et al. JACS 144, 10025, 2022; Lee et al. Science Advances, 9, eadg415, 2023). Finally, conceptual advancement as to how these findings contribute to better understand igneous, impact, deformation, and seismic processes in the Earth and planetary surfaces and deep interiors are highlighted.

[Plenary] Impact of Climate Change on Groundwater Resources and Way Forward

Elango LAKSHMANAN[1]*, Indian Institute of Technology Madras, Chennai-600036, Tamil Nadu, INDIA. (elango34@hotmail.com)

Abstract

Climate change and other issues, such as increasing urbanisation and food and energy requirements, affect groundwater resources. Climate change affects groundwater resources in multiple ways. The coastal groundwaters are more vulnerable to climate change-induced stresses. Climate change's adverse impacts on water quality are of emerging interest and importance. Coastal groundwaters are affected by changes in rainfall patterns, urbanisation, and rising sea levels. This study brings out the impact on coastal regions of India. The study analysed the long-term groundwater level data and used numerical modelling. The study indicates that parts of coastal aquifers in India are affected by seawater intrusion. The fresh coastal groundwater resources are diminishing due to rising sea levels and overuse. Improving recharge and reducing the pumping are some of the mitigation measures to overcome this problem. On the other hand, analyzing water quality also provides insights into how weathering within a river basin impacts climate change and the carbon cycle. Carbon dynamics within catchments and river basins are pivotal to climate change processes. This session will delve into these topics, examining current research on water quality, surface water-groundwater interactions, the carbon cycle, riverine flux, organic and inorganic carbon, models, and more, all within the context of climate change.

[Plenary] Significance of bathymetric features on tsunami propagation in Indianan Ocean

Kirti SRIVASTAVA[1]*, CSIR-NGRI (kirtingri722@gmail.com)

Abstract

The Indian Ocean Tsunami in 2004 damaged several areas along the east coast of India, ruining many structures along the coasts and causing loss of human life. Tsunamis are giant waves caused by undersea earthquakes, landslides, meteorites, or volcanic eruptions. Their severity depends on the magnitude and distance from the shore. The tall and fast-moving waves destroyed property on a very large scale and rebuilding them is a huge task. Designing the coastal structures to resist or at least reduce the damage caused by a tsunami wave would save a lot of time and money. It also helps to reduce impact forces and inundation of the wave. Challenging questions need to be addressed and looked into the tsunami propagation and the hazard associated with the tsunamis in the Indian Ocean. Different aspects of the tsunami propagation over ridges, islands, and along the east and west coast of India due to tsunamigenic earthquakes from the Andaman-Sumatra and Makran Subduction zones are studied. Also, tsunami forces on different beaches and also the effect of varying bathymetry in the Indian Ocean will be brought out. The effectiveness of having rock boulders along the coast for reducing the tsunami impact on the coast is quantified. Due to their structure, the waves hit the boulders in different directions causing the wave energy to dissipate in all directions. Eventually, the surge wave breaks and loses its velocity. Hence, no inundation or a slight overflow is observed. The tsunami-induced forces study earlier was not given importance due to the low frequency of tsunamis. After the destructed buildings and many other damaged structures during the 2004 tsunami, importance is being given to tsunami forces in engineering constructions along tsunami-prone areas. Hence, instead of building sea walls if we use rock boulders along the populated coastal areas the damage can be minimized. Keeping in view the destructive tsunamis in the Indian Ocean and other possible destructive tsunami events due to landslides and meteorites are investigated and their findings shall be discussed.

[Plenary] Artificial Intelligence (AI) - a new era for the modeling and interpretation of natural hazard assessments in the spatial domain

Biswajeet PRADHAN[1]*, University of Technology Sydney (biswajeet24@gmail.com)

Abstract

In this keynote talk, we explore the transformative impact of Artificial Intelligence (AI) on natural hazard assessments within spatial domains, heralding a new era in disaster management. AI technologies have emerged as powerful tools, revolutionizing the way we model and interpret natural hazards. By harnessing machine learning algorithms and big data analytics, AI enables the efficient processing and analysis of vast spatial datasets, leading to highly accurate and timely hazard assessments. Real-time integration of geospatial information empowers proactive disaster preparedness, ensuring swift and precise responses to evolving threats.

Crucially, AI brings a paradigm shift in interpretation, unraveling intricate spatial patterns and relationships in natural hazard data. Its advanced algorithms discern subtle correlations and hidden trends, enhancing our understanding of complex environmental processes. This newfound insight not only refines hazard models but also informs adaptive strategies for risk reduction and resilient infrastructure development. Through case studies and cutting-edge applications, this keynote explores how AI-driven models and interpretations are reshaping our approach to natural hazard assessments. By embracing this innovative intersection of technology and geoscience, we pave the way for a safer and more resilient future, where AI becomes a cornerstone in our collective efforts to mitigate the impact of natural disasters and protect vulnerable communities.

[Plenary] The Roles Geoscientists Can Play to Achieve the United Nations Sustainable Development Goals

Adam SIMON[1]*, University of Michigan (simonac@umich.edu)

Abstract

The United Nations Sustainable Development Goals call for, among other things, correcting asymmetric access to energy that will allow all members of our global community to have a quality of life common for citizens of more advanced economies such as the Republic of Korea, European Union and the United States. Access to at the country level can be evaluated by using the United Nations Development Programme Human Development Index that considers the life expectancy at birth, the expected years of schooling and the gross national income per person. The magnitude of income inequality within a country can also be used as a fourth dimension to yield an IHDI, as can gender equality and the level of individual freedom that yield an Augmented HDI (AHDI). An assessment of the AHDI values for all countries reveals stark differences among countries and regions. The AHDI value is 0.759 for the United States, Canada, Australia and New Zealand, 0.748 for Western Europe, 0.546 for Eastern Europe, 0.457 for Latin America, 0.432 for East Asia, 0.343 for the Middle East, 0.340 for North Africa, 0.336 for South Asia and 0.275 for Sub Saharan Africa. Certainly, there are differences among countries within each region, but the data reveal stark differences that indicate where capacity building is most needed. Capacity building requires capital in the form of one or more resources that a country can export to generate revenue for development. Resources include human labor, agricultural products and natural resources such as cobalt, copper, gold, lithium, nickel, etc. The latter group of resources to varying degrees are abundant in all regions, but unlocking the value of these resources requires the careful work of Geoscientists to explore for, discover, and determine the quantity of a particular resource. Essentially, geoscientists are treasure finders and hold the keys to unlocking the value of resources that can be used for capacity building and human development. Providentially, global demand for all of these metal resources is at an all-time high and will only increase over the next several decades. Geoscientists also play the important role of minimizing impacts to the environment during exploration and mine development. In this talk, I will discuss our current understanding of the global locations of mineral resources, their potential value if they could be exploited, and related this value to what is required to achieve the United Nations Sustainable Development Goals.

[Plenary] A Trip to Dinosaur Time - Records from Continental Scientific Drilling of Cretaceous Songliao Basin

Chengshan WANG[1]*, Research Center for Tibetan Plateau Geology, China University of Geosciences (Beijing) (chshwang@cugb.edu.cn)
Yuan Gao[2], School of Geosciences and Resources, China University of Geosciences (Beijing)
Pujun Wang[3], College of Earth Sciences, Jilin University
Huaichun Wu[4], School of Ocean Sciences, China University of Geosciences (Beijing)
Qingtian Lv[5], Chinese Academy of Geological Sciences

Abstract

Over the past centuries, the Earth's climate has been consistently warming, and may enter a greenhouse climate state with ice-free poles in the future. The Cretaceous was a typical period of greenhouse climate in deep time, and thus understanding the Cretaceous climate is significant for interpreting past climate changes and predicting future trends. The International Continental Scientific Drilling Project of the Songliao Basin is the world's first continental scientific drilling project to penetrate the Cretaceous continental strata within the framework of the ICDP. This project is aimed to investigate Cretaceous terrestrial climate and environmental changes, and to explore the mechanisms of massive terrestrial organic matter accumulation and enrichment. Spanning 16 years, this project achieves a continuous and complete 8187-meter core with a recovery rate exceeding 97%, establishes a high-precision chronostratigraphic framework for the Cretaceous continental strata in the Songliao Basin, reconstructs multi-temporal-scale terrestrial climate cycles and climate events during the Cretaceous period, reveals the mechanisms of Cretaceous sea-level fluctuations, and confirms marine incursion events in the Songliao Basin. The International Continental Scientific Drilling Project of the Songliao Basin has promoted global collaboration among geologists to study Cretaceous greenhouse climates, leading to a series of high-level academic achievements. It has provided crucial scientific support for the sustainable development of oil and gas exploration in the Songliao Basin, and has generated significant social benefits and substantial international and domestic influence. The International Continental Scientific Drilling Project of the Songliao Basin represents a milestone stage in exploring deep-time Earth, and it is foreseeable that in the future, with the aid of scientific drilling, humanity will continually enhance the understanding of deep-time climatic and environmental evolution.

Geochemistry and detrital zircon U–Pb geochronology of Neogene sedimentary rocks from offshore Bengal Basin, Bangladesh: Implications for provenance and tectonic setting

Julleh Jalalur RAHMAN[1]*, Jahangirnagar Universty (rahman65@juniv.edu)
Tanusree Datta[2], Jahangirnagar University
Abu Sadat Md. Sayem[3], Jahangirnagar University
Md. Sakawat Hossain[4], Jahangirnagar University

Abstract

The Bengal Basin is one of the most productive sedimentary basins in the world for hydrocarbons and is situated in the northeastern section of the Indian subcontinent. The basin contains dominantly shallow-marine to continental clastic and minor carbonates and attains a thickness of about 18 km of mainly Tertiary to Recent sediments, with more than 6 km of Neogene sediments. The thickness of the sediment gradually increases from the north-west to the south-east. The Sangu Gas Field is located in Block SS 04 at the eastern part of the Hatiya Trough of the Bengal Foredeep and the western extremity of the Chittagong-Tripura Fold Belt (CTFB). This research aims to understand the provenance and tectonic evolution of the offshore Neogene sequences encountered in Sangu -1 and Sangu-5 wells from the Sangu Gas Field, Bay of Bengal, based on framework mineralogy, geochemistry and U-Pb dating of detrital zircons. Framework composition reveals that the Neogene sandstones are more quartzose ones with low feldspar, very few volcanic grains, and abundant sedimentary and low-grade metamorphic lithic clasts, indicating that the sandstones were derived from a quartzose recycled orogen province, such as a fold-thrust belt and a collision suture. Major and trace element geochemical studies show that these Neogene sediments originated from an active continental margin (ACM) tectonic setting related to the recycled orogen province that is in good agreement with the framework composition of the sandstones. The recycled sources are characterized by felsic source rocks and underwent low to moderate chemical weathering, as indicated by the CIA (Chemical Index of Alteration) values ranging from 55 to 73, which are supported by the PIA (Plagioclase Index of Alteration) (57-84, avg. 70) and the ICV (Index of Compositional Variability) (average 1.2) values. The U-Pb dating data of detrital zircons show that most of the zircon grains of the Neogene succession in the Sangu Gas Field of the Hatiya Trough are Proterozoic and early Paleozoic in age. The U-Pb ages of the Pliocene-Pleistocene Tipam Group and the Miocene Surma Group range from 22.49 to 2794.45 Ma and 28.04 to 3168.21 Ma, respectively. The detrital zircon U-Pb age spectra of the Miocene Surma Group and Pliocene Tipam Group reveal that the main source of the detrital zircons was a mixture of the three Himalayan litho-tectonic units; the Tethyan Himalaya, the Higher Himalaya, and the Lesser Himalaya. The dominant peak of zircon ages at ~440-620 Ma from the Tipam and Surma Group sandstones resembles those of the Tethyan Himalaya (TH), Upper Lesser Himalaya (ULH), and Indo-Burman Ranges (IBR). The subordinate peaks at ~ 1500-2000 Ma reflect the ages of the Higher Himalaya (HH). The other subordinate peaks at ~ 700-1200 Ma and ~ 2500

Ma, reflect the age of the Lower Lesser Himalaya (LLH). There is a significant rise in the younger detrital zircons (<200 Ma) population in the Pliocene Tipam Group (~22%), which may be attributed to the possible source from the Gangdese arc, the Trans-Himalayan Batholiths, and the Burma magmatic arc.

Future drilling in Bengal Fan revealing the plateau uplift and its effects from the seafloor spreading to the climate change

Gang HU[1]*, Qingdao Institute of Marine Geology (qimghgang@gmail.com)

Abstract

The Bengal Fan is not only a source-sink transition zone connecting the plateau and the deep sea, but also an important product of plates drift and collision. Its deep sedimentary records are the natural archives of the India-Eurasia plate collision, the uplift and erosion process of the Qinghai Tibet Plateau and the evolution of climate and environment. We summarized the drilling expeditions and the latest research progress focusing on the sedimentary process and climate evolution since the late Miocene, the nature and evolution of the 90°E Ridge, and the formation of the South Asian monsoon in the Bengal Fan. However, constrained by drilling capacity and scientific targets, the full time sedimentary strata, the age and structural characteristics of the underlying oceanic crust in the Bengal Fan have not been effectively revealed which hinders the research on the long-time scale source to sink transition, the South Asia Monsoon formation and plate reconstruction. Based on the recently acquired high-quality multi-channel seismic data, the basement fluctuation, sedimentary structure and tectonic development characteristics of the Bengal Fan downstream are interpreted. Furthermore, we proposed three future scientific drilling locations which aim at the scientific drilling objectives including the complete sedimentary strata, age of oceanic crust basalt, and special structure characteristics. Well calibration and lithology prediction are carried out for these proposed sites respectively. These proposed sites are not only contributed to the reserve of scientific drilling for Chinese Ocean Drilling Vessel, but also significant for solving the frontier scientific issues of the Qinghai Tibet Plateau.

Cenozoic forearc and backarc basin-filling stratigraphy as an archive of tectonic controls on depositional styles and cycles along the north-western Pacific margins

Osamu TAKANO[1]*, JAPEX Research Center (osamu.takano@japex.co.jp)

Abstract

Basin-filling stratigraphy can be defined as “the study of basin-filling sediments from the standpoints of unconformity events, succession trends and three-dimensional development patterns of depositional systems with consideration of their controlling factors such as background basin tectonics and plate tectonic conditions.” The basic unit of basin-filling stratigraphy can be a tectono-sequence unit, which can be bounded by regional major unconformities, or the turning points of basin evolution stages and succession trends of depositional systems such as upward shallowing and deepening trajectories. This paper attempts to examine the forearc and backarc basin-filling stratigraphy of the NE and SW Japan arcs to obtain the background tectonics as major controlling factors, which might be reflecting the plate tectonic scenarios along the north-western Pacific convergent margins.

The basin-filling stratigraphy of the NE Japan forearc basins can be divided into the lower Cretaceous to Paleogene succession and the upper Neogene succession. The Cretaceous to Paleogene succession below the “Ounc” unconformity was deposited under the trench slope break-uplifted, overfilled-type forearc setting, which formed thick aggradation of bay to coal-bearing fluvial systems, whereas the Neogene succession above the “Ounc” unconformity was deposited under the deeper-marine sloped to submerged ridge-type forearc setting, which formed a transgressive succession of deeper marine turbidites or shales. This drastic change in the forearc basin type and successions is considered to have reflected by the onset of tectonic erosion of the subducting Pacific Plate.

The basin-filling stratigraphy of the SW Japan forearc basins can be divided by the latest Oligocene to Middle Miocene gap into two parts: the lower Cretaceous to Paleogene Shimanto-type forearc/accretionary complex and the upper Neogene normal forearc succession. The Neogene forearc succession is mainly composed of deeper marine submarine-fan turbidite successions and slope-to-basin-floor mudstones. The Neogene basin-filling succession is frequently interrupted by regional unconformities, which commonly show a systematic diachronicity, possibly reflecting gradual shifts of a tectonic event.

The basin-filling stratigraphy of backarc to intraarc basins along the NE and SW Japan arcs is characterized by the basin evolution stages, since these backarc/intraarc basins were initiated as rift basins, and followed by tectonic inversion into a compressional stress field. The mass balance between the accommodation space created by subsidence and sedimentation may control the succession trends for the syn-rift, post rift and tectonic inversion stages. The syn-rift to early post rift stage usually shows a transgressive upward-deepening succession trend, whereas the tectonic inversion stage causes an upward-shallowing trend due to increasing sediment supply from the

provenance.

Geochemical Investigation in the Yellow Sea Reveals the Integration of the Modern Yellow River

Xiangtong HUANG[1]*, State Key Laboratory of Marine Geology, Tongji University
(xiangtong@tongji.edu.cn)
Xi Mei[2], Qingdao Institute of Marine Geology
Shouye Yang[3], State Key Laboratory of Marine Geology, Tongji University

Abstract

The South Yellow Sea is an important sink for sediments delivered by the Yellow and Yangtze rivers in East Asia. We conducted a high-resolution geochemical analysis on the bulk sediments retrieved from a marine drill core (CSDP-1) using the method of X-ray fluorescence (XRF). Our results show large geochemical variations along the core. As demonstrated by linear correlations along with the Al-Si link in a compositional principal component analysis (PCA), the variations in elemental ratios among Al, K, Zr, Ba and Si are primarily controlled by the sediment grain-size or sorting effect. A closer examination of these geochemical proxies regarding the present Yangtze and Yellow rivers indicates a gradual shift of sediment provenance from the Yangtze to the Yellow River catchment in the core. With the help of a fuzzy c-means cluster analysis on elemental ratios of Al/Si, Al/Ti, K/Si as well as the chemical index of alteration (CIA), the timing of a major provenance change in the core is narrowed down to 1.5-1.7 Ma. This timing corresponds to a major seismic and sedimentary boundary (T2) in the Yellow Sea Basin and coincides with the onset of fluvial terrace deposition and incision in the middle and upper reaches of the Yellow River. As a result, we argue that the major provenance change derived from geochemical variations in the Yellow Sea sedimentary basin can be linked with the integration of the modern Yellow River. The provenance change is likely caused by a coupling between regional tectonic deformation and the Asian summer monsoon enhancement in the early Pleistocene.

Kurian P J[7], National Centre for Polar and Ocean Research, Headland Sada, Vasco da Gama
Rajveer Sharma[8], Inter University Accelerator Center (IUAC), New Delhi 110 067, India.

Abstract

The input of peninsular Indian rivers to the sediment load of the continental shelf in south-eastern India, the western Bay of Bengal, is relatively less appreciated. The present study infers terrigenous influx, palaeo-weathering, and palaeo-rainfall conditions over the past 23 ka, employing mineral magnetic proxies which is corroborated by particle size, diffuse reflectance spectroscopic, and Fourier Transform Infrared Spectroscopic techniques. The changes in terrigenous influx and chemical weathering are understood by the parameters like magnetic mineral concentration (SIRM, χARM, χlf), grain size (χARM/SIRM, SIRM/χlf, and χARM/χlf), and mineralogy (s-ratio). The magnetic data is substantiated by proxies such as hematite/goethite ratio, particle size (percentages of sand, silt, clay), CaCO3, and kaolinite content. A gradual increase in the winter monsoon is documented during the period from 23000-17000 cal. years B.P. (Last Glacial Maxima), followed by a steady phase (17000-10000cal. years B.P.). However, a brief decline in rainfall is observed around ~13900cal. years B.P. (Bølling-Allerød), with an increase during ~12900-11800 cal. years B.P. (Younger Dryas). The Early Holocene period is characterized by increased detrital influx to the core site, strong pedogenesis, and chemical weathering in the continental areas in response to high rainfall conditions. A significant shift in sediment provenance in the continental shelf region of the core site, coupled with a weakening of monsoon, is observed since 4900 cal. years B.P.

Continental weathering signal propogation in East Asian continental margins

Shouye YANG[1]*, Tongji University (syyang@tongji.edu.cn)

Abstract

East Asia continental margin is unique because it bridges the largest Euroasian continent and largest Pacific and receives huge terrestrial materials from surrounding landmasses. It is featured by two major types of fluvial sediment routing systems: the mega-rivers in Eurasian continent, e.g. the Changjiang (Yangtze) River, and the small mountainous rivers in Taiwan Island and SE China, e.g. the Zhuoshui River and Mulanxi River. Among which, the small mountainous rivers are relatively less investigated although they play a disproportionate role in sediment discharge and greatly influence the terrestrial material cycle in the West Pacific. Here, we present the data of multiple isotopic proxies (Be, Sr, Nd, Li) to trace the silicate weathering and sediment source-to-sink processes in the large river systems and small mountainous catchments (Zhuoshui and Mulanxi Rivers) in the East Asian continental margin, and particularly the weathering mechanisms and environmental signal propagation in the catchments will be discussed. We observed the conservative behaviour of dissolved Sr-Li during the mixing processes of Changjiang Estuary, while the particulate forms display fractionations. The small dynamic mountains rivers in Taiwan exhibit large sedimentary geochemical and provenance heterogeneity despite their fast sediment transfer from land to sea, which limits the silicate weathering intensity. Comparatively, the transport-limited weathering regime is observed in the small river basins in SE China and the river sediment source-to-sink processes are greatly influenced by strong tide in the estuaries. Our study provides more constraints on the earth surface processes in East Asia continental margin.

A long-term decline of δ26Mg values of clay-sized sediments in the past 430ka: the weakening of East Asian monsoon since the Mid-Brunhes Event?

Zhongya HU[1]*, Tongji Univeristy (zhongyahu@tongji.edu.cn)
Shouye Yang[2], Tongji Univeristy
Simon Hohl[3], Tongji Univeristy

Abstract

studies of weathering profiles demonstrate that the octahedrally bound structural Mg in clay minerals is generally enriched in heavy Mg isotopes and δ26Mg values of saprolite generally increase at higher degrees of weathering. At present, magnesium isotopic compositions in clay-sized sediments deposited in marginal sea environments show the potential to trace the variation of silicate weathering on a continental scale. In this study, to refine the response of silicate weathering to the climatic variability on the orbital scale, we performed systematic analyses on the mineralogical, elemental and Mg isotopic compositions of clay-size silicate fractions from the MD05-2901 drill core in an upwelling region of the open South China Sea (SCS). Pre-leached clay-size silicate fractions have flat UCC-normalized REE distribution patterns, with a relative depletion of mobile elements in the sediments, well matching the order of elemental mobility during chemical weathering (Na > Ca ≈ Sr > Mg > K), indicating products of silicate weathering as primary source. Our obtained δ26Mg values display a long-term decline over the past 430 kyr, ranging from ca. 0.02 ‰ to -0.10 ‰, revealing no correlation with glacial-interglacial cycles or the relative proportion of different clay minerals. Instead, these results are analogous to the temporal decline in boron isotopic compositions from a loess-paleosol sequence in Northeast (NE) China that was previously linked to the weakening of the East Asian Summer Monsoon (EASM) after the Mid-Brunhes Event. We infer that the gradually declined intensity of the EASM potentially led to a reduced degree of silicate weathering on continental Asia, ultimately recorded in decreasing δ26Mg values in clay-size fraction sediments deposited in the SCS in the past 430ka.

Re-examination the Sediments Provenance of the Eastern Sunda Slope Since the Last Deglaciation with Geochemical Methods

Junfei CHEN[1]*, State Key Laboratory of Marine Geology, Tongji University (geojfchen@tongji.edu.cn)
Chao Li[2], State Key Laboratory of Marine Geology, Tongji University
Albert Galy[3], Centre de Recherches Pétrographiques et Géochimiques, CNRS, Université de Lorraine
Shouye Yang[4], State Key Laboratory of Marine Geology, Tongji University

Abstract

The Sunda Shelf (SS), located in the low-latitude tropical region, has remained tectonically stable since the late Quaternary. It is the largest and shallowest continental shelf with the least slope, making it highly sensitive to sea level changes. The SS is influenced by the Asian monsoon, which receives a significant amount of terrigenous detritus, making it a natural laboratory for studying low-latitude material cycling, climate change, and carbon cycling. However, studies on the sediment provenance of the SS and the southern South China Sea (SCS) since the late Quaternary are limited, with most focusing on qualitative sedimentology, which hinders research on climate change and global carbon cycling. This study collected three types of samples from the SS: surrounding land river sediments, shelf surface sediments, and slope core sediments. Bulk carbonate-depleted detrital component analyses of Sr, Nd, and elements were conducted. Previously published Sr, Nd, and element data of surface sediment samples from the SCS were also analysed. By integrating and analyzing a large amount of geochemical data, this study re-examined the sediment provenance and controlling factors of sediments on the eastern slope of the SS since the last deglaciation. The results indicate that during high sea level period, sedimentation rates were very low, and slope sediments mainly originated from the SS. This mechanism involved disturbances to local shelf surface sediments by storms, which were then transported along the slope and deposited. Current studies suggest that deposits near the coast (islands) of the SS is predominantly from nearby sources, while sediments in the central and most areas of the SS originates from large rivers in the north (e.g., the Mekong River, Red River, and rivers in Thailand). Therefore, it can be inferred that during high sea level periods, sediments primarily originate from large northern rivers. During low sea level periods, the SS was exposed as vast land, with the development of two paleoriver systems. During this period, sedimentation rates on the slope were ten times higher than that during high sea level period, with large amounts of island sediments transported directly to the slope through paleoriver channels. At the same time, geochemical data also indicate an increased proportion of material from southern islands, such as Sumatra and Borneo. In conclusion, sediment provenance on the eastern slope of the SS has undergone a transition since the last deglaciation, shifting from younger southern island sources during low sea level period to older landmass in the north during high sea level period.

Holocene geomorphological evolution of a sediment-starved coastal embayment in response to sea level change: Insights from the Qing'ao Embayment, southern China

Abstract

Aiming to gain a better understanding of the response of sediment-starved coastal systems to the climate-driven sea level change, this study examines the Holocene evolution history of Qing'ao Embayment, southern China, as a case study. Results suggest three distinct stages of the evolution history: Stage 1 (8400-6000 cal yr BP) relates to an early Holocene basin-wide shell-rich clayey silt sequence, that is found overlying the bedrock or weathered sediments. This facies records an initial sedimentation phase associated with the early Holocene marine transgression into the embayment. Stage 2 (6000-3000 cal yr BP) relates to the development of fine- and medium-sandy inshore/open-bay facies. This facies records early sediment deposition under relatively strong hydrodynamic environment during early marine regression. Stage 3 (3000 cal yr BP to present) records two substages: Stage 3a relates to the semi-enclosed bay, intertidal and lagoonal salt marsh facies between 3000 and 1300 cal yr BP, and Stage 3b records the final infilling of the embayment into a lagoonal plain. This evolution model suggests that the rates of sea level change and sediment accretion are the two major controlling factors for the Holocene geomorphological evolution of sediment-starving coastal systems.

Comparison of the evolution of Qing'ao embayment with sediment-supply rich large-river estuary/deltas reveals unique features in the response to Holocene sea level change of this sediment-starved embayment: During the early Holocene marine transgression, sediment starts to accumulate in the small embayment around 8400 cal yr BP, hundreds of years later than in large river estuaries. During 8400-6000 cal yr BP, sediment accretion rate remains dramatically lower than sea level rise rate, which results in the quick growth of sediment accommodation space during this stage. Around 6000 cal yr BP, though sea level has remained relatively stable and large-river deltas have been growing for about 1000 years, the sediment-starved embayment was still under shallow marine and/or open bay conditions. At 3000 cal yr BP, shoreline started to prograde in sediment-starved embayment, which is about 3000 years later than large river deltas. Finally, agricultural activity started around 1300 cal yr BP in the embayment, thousands of years later than large river deltas. Limited or minimal fluvial sediment supply to the small embayment has constrained the land expansion during the sea level stabilization since mid-Holocene, and the

limited living space might result in the much later agricultural activity in such coastal system.
Due to the different balances between sea level change and sediment flux, sediment-starved coasts are expected to be under higher risks than large river deltas. However, earlier and more extensive human activities in large river basins have resulted in the reduction of sediment discharge that heighten the risks of large river deltas against future sea level rise. Thus, more attention should be paid to the coastal sediment supply budgets in the context of the background of rising sea level.

Marine to Continental transition in Chakrata to Rautgara Formation, Inner Lesser Himalaya (ILH), Uttarakhand, India

ALOK DEEP[1]*, DEPARTMENT OF GEOLOGY, UNIVERSITY OF DELHI, DELHI, INDIA (alokdeepgeo@gmail.com)
PARTHA PRATIM CHAKRABORTY[2], DEPARTMENT OF GEOLOGY, UNIVERSITY OF DELHI, DELHI, INDIA
ADITI SHARMA[3], DEPARTMENT OF GEOLOGY, UNIVERSITY OF DELHI, DELHI, INDIA

Abstract

A 80 km long traverse in the north-northeast of the Chakrata town, Uttarakhand, India allowed documentation of marine shelf (sandstone-shale heterolithic Chakrata Formation) to continental fluvial (arenaceous Rautgara Formation) transition in the Paleoproterozoic Inner lesser Himalayan (ILH) succession. Decimeter to meter-thick fine-grained sandstone-fissile grey to black shale (phyllite) alternation represents the shelf succession. Storm intervention on the Chakrata shelf is attested in the presence of hummocks and gutters within the sandstone intervals. Lower surfaces of hummocky beds are downcurved at places in form of gutters, truncating the underlying shale lamination. In cross-section gutters are both symmetrical and asymmetrical in geometry and gutter fills are massive, symmetric or asymmetric in character. In contrast, amalgamated sheet-like beds of poorly-sorted medium to coarse grained sandstone with occasional interbeds of conglomerate represents the continental fluvial succession of Rautgara Formation. In terms of 'architectural element' the sheet sandstones are recognized as 'SS' element, internally constituted of facies units Sm (massive), Sh (plane-laminated), St (trough cross-stratified) and Sr (ripple laminated). Interbedded matrix-supported conglomerate units are identified as Gsm facies unit. A distal braided fluvial model is proposed for the Rautgara Formation in the studied section.

Intense deformation of strata often restricts the observation of relationship between different lithosomes of ILH. The Chakrata- Rautgara contact in present case is also no exception. Despite this hindrance, the contact is identified as sharp and mild erosional. Incoming of a fluvial system right onto the shelf is interpreted as signature of forced regression. High feldspar content in the fluvial sandstone, presence of pebble/cobble sized extra-basinal clasts in the Gsm facies unit bear indication of tectonic perturbance behind the forced regression event. Additionally, presence of meters-thick channelized conglomerate unit within the fluvial succession bear indication of prolonged tectonic seiches in course of Rautgara sedimentation.

SEDIMENTATION AND GROWTH OF PROTEROZOIC CRATONIC BASINS: LESSONS FROM PURANA BASINS, INDIA

SHILPA PATIL PILLAI[1]*, IISER PUNE (shilpatil24@gmail.com)
VIVEK KALE[2], ACWADAM, PUNE

Abstract

The Purana Basins of Peninsular India host significant sedimentological, environmental and tectonostratigraphic data of the Proterozoic geohistory of the Greater Indian cratonic block. They are (i) Vindhyanchal (ii) Chattisgarh, (iii) Khariar - Indravati, (iv) Cuddapah, (v) Bhima, (vi) Kaladgi, and (vii) Pranhita-Godavari basins. These seven basins are the repositories of marginal marine to shallow marine sedimentary successions deposited in peri-, intra-, & inter-cratonic settings. The sediments of these basins rest uncomformably on the continental crust of Archean to Paleoproterozoic ages, but often also display tectonic contacts with them and the adjoining contemporary mobile belts.

In the present study, we examine the sediment accumulation patterns within each of the basin (as a proxy for their subsidence history) to assess the tectonic evolution of the Purana basins within the framework of Proterozoic supercontinental cycles. It has been shown that while detrital siliciclastic sedimentation dominated during phases that were coeval with supercontinental assembly, the intervening phases had a dominance of carbonate and argillaceous sediments.

We have constructed synthetic subsidence curves for each basin using formation-level de-compacted thickness, depositional depths and the available geochronological data. Thermal sag interspersed with tectonic subsidence can be demonstrated to have driven basin dynamics in most of these poly-history basins, with sedimentation patterns akin to intracontinental and modern passive continental margin settings. The synthetic subsidence curves of these basins match well with Phanerozoic analogues. When interpreted in conjunction with other allied aspects such as their structural configuration and coeval tectonic events in the adjoining crustal blocks, it can be shown that they have a close affinity to contemporary global supercontinental cycles.

Glauconite a marker horizon for understanding paleoenvironment and depositional systems in the Mesoproterozoic Vindhyan Basin, Central India

Satya PRAKASH[1]*, Geological Survey of India (satya.prakash@gsi.gov.in)
Vivek Prakash Malviya[2], Department of Applied Geology, Dr. Harisingh Gour Viswavidiyalaya, Sagar-470003 India
Jai Prakash Verma[3], Institute of Environmental and Sustainable Development, Banaras Hindu University, Varanasi-221005, India
Kezhasilie Chiezou[4], Geological Survey of India, North Eastern Region, Shillong- 793006, India

Abstract

Glauconite is one of the indicator minerals of sedimentary facies, widely developed in the Proterozoic and Cambrian era. Due to the limited number of palaeoproxies in the Vindhyan basin, it is very difficult to deduce the deposition environment.The present study of glauconite from Semri Group, lower Vindhyan sequences of Paleoproterzoic age provides tremendous geological significance for the reconstruction of paleogeographic setting in basins.

The Vindhyan basin represents one of the largest Proterozoic intra-continental basins in central India. The Semri Group of rocks are lower Vindhyan strata of Son valley, composed of calcareous, argillaceous sediments with glauconitic layers in the marine environment, and Kaimur Group represent the Upper Vindhyan composed of arenaceous sediments formed in the fluviatile and estuary environments.

The detailed stratigraphic section and facies level studies of Semri strata revel three glauconite facies associations occurring from deeper to shallower levels, viz. i)green shale-silt- glauconite ii) glauconitic-calcareous siltstone and iii)glauconitic sandstone. The three levels of glauconite facies represent the phase of continuous shallowing of the Vindhyan basin. Glauconite facies sequences of Semri Group reflect that green shale-silt- glauconite facies formed at the deeper level, Glauconitic-calcareous siltstone formed at the intermediate level, and finally the dominant glauconitic sandstone association formed at the shallower level. Total glauconite content increases upward from lowstand systems tract (LST) (glauconitic-green shale facies) to transgressive systems tract (TST) (calcareous-silt shale, minor glauconitic facies) and to condensed section (CS) of glauconitic sandstone. The maximum glauconite contents are found in condensed section (CS). The glauconite decrease towards the highstand systems tract (HST) and is absent in the overlying strata represented by Rohtas limestone and shale. The glauconite itself is indicative of a larger sediment starvation period, which is representative of the transgressive-retrogressive phase. However, the overlying limestone and shale-dominated facies represent the submergence of the basin.

Petrographic studies show that glauconitic sandstone (CS) comprises glauconite and quartz grains with a minor amount of K-feldspar, plagioclase, and lithic fragments. Modal analysis classification suggests the glauconitic sandstone (CS) as quartz arenitic of arkosic-subarokic nature. Further thin section studies reveal that the grain of glauconite becomes coarser as we go

higher in the stratigraphic position.
Glauconitic shale contains large amounts of illite with glauconite in LST. The relative abundance of matured form of glauconite particle morphologies are more inclined to contain glauconite pellets (CS), while minor detrital glauconite is regularly observed in the LST and TST, which are authigenic in nature. Glauconitization took place on the substrate of detrital K-feldspars and clay peloids, as evident from the petrographic studies. Glauconite minerals mostly occur in grain and pellet form, and the cementing materials are siliceous and ferruginous. On the basis of geochemical results, glauconitic sandstones are classified into arkose, sub-litharenite, and quartz arenitic. The CIA values indicate that the weathering in the source region was moderate to intense. Glauconitic facies of the Semri Group represent a condensed stratigraphic section formed in the littoral to sub-littoral zone of the continental shelf under transgression and suggests the sequential upliftment of the Vindhyan basin.

Extensive chemical weathering and its response to Quaternary glacialinterglacial cycles in the South China Sea: Evidence from Li isotope systematics

Fangbing LI[1]*, Tongji University (fangbingli@tongji.edu.cn)
Simon Hohl[2], Tongji University
Marc Weynell[3], Freie Universität Berlin
Shouye Yang[4], Tongji University

Abstract

Climate is the crucial factor controlling continental chemical weathering. While warm and humid conditions at low latitudes and altitudes during interglacial periods promote chemical weathering, cooler and dryer conditions suppress weathering rates during glacial periods. However, moderate temperature and precipitation rates at low latitudes, in combination with exposed shelf sediments during sea level low stands, may also promote increased secondary mineral formation even during glacial periods.

This study reports major and trace element compositions and stable Li isotopic compositions obtained in clay-sized silicate sediments of the drill core MD 05-2901 off the coast of Central Vietnam. The core comprises 14 marine isotope stages reaching back ~450 kyr and presumably records glacial-interglacial cycles in an upwelling regime of the South China Sea. After removing any effects from grain size and sediment provenance compared to previously published clay mineralogy from the same core, Li isotopic compositions of the silicate fraction show interglacial-glacial fluctuation (δ^7Li =-1.06 to 0.52 ‰). lighter values (~-1.06 ‰) in chlorite and illite-dominated sediment beds, deposited during glacial periods, i.e., at heavier δ^{18}O in associated benthic foraminifera, indicate stronger weathering (and secondary mineral formation) than sediments deposited during interglacials. The here-reported enhanced chemical weathering during glacial periods likely resulted from exposed shelf sediments onshore during lower sea level stands. As a result, sea-level change is the second dominant but easily neglected factor for strengthening the chemical weathering and secondary mineral formation and its archiving in shelf sediments during glacial-interglacial periods.

Shouye Yang[4], State Key Laboratory of Marine Geology, Tongji University, Shanghai 200092, China

Abstract

The Indo-Gangetic Plain, a foreland basin, was formed by deposition of sediments derived from the Himalaya. The alluvial sediments of the Indo-Gangetic Plain are originated as a result of tectonic and climatic factors governing the exhumation and erosion of the Hinterland Himalaya and delivered to the plain via several large rivers. However, erosion distribution over the Himalaya and sediment delivery to the plain, on a shorter millennial timescale, are reported to be mainly controlled by the climatic factors such as intensity of Indian summer monsoon (ISM) rainfall and glacial cover over the Himalaya. But there exist contradictory records on the catchment erosion in response to climate change along the strike of the Himalaya. Here we present Sr and Nd isotope compositions in bulk sediment samples from two ~48 m long sediment cores collected from a buried channel of the paleo-Yamuna River in the northwest Indo-Gangetic Plain, Haryana to better understand the link between the climate and distribution of erosion over the Himalaya during the late Quaternary. Significant temporal variations in 87Sr/86Sr (0.73424–0.79241) and 143Nd/144Nd (εNd: –14.0 to –19.7) ratios of the sediments are observed, suggesting variable contributions from isotopically distinct Higher Himalaya and Lesser Himalaya end-member sources in the catchment. Down-core variability exhibits an increase in εNd values (and decrease in 87Sr/86Sr) during early and late marine isotope stage (MIS) 3 and early MIS 1 periods. This indicates increased contribution from the Higher Himalaya end-member due to receding glacial cover over the Himalaya, and intense ISM and its migration into the deeper part of the Higher Himalaya during early and late MIS 3 and early MIS 1 periods resulting in more erosion of the Higher Himalaya.

Relative Sea Level Controls and Depositional Dynamics in a Neoproterozoic rimmed shelf of Narji Limestone Formation, Kurnool Group, India: Insights from Facies Analysis and Isotope Signatures

RASIKH BARKAT[1]*, CoEES, Oil India Limited (rasikhbarkat@gmail.com)
PARTHA PRATIM CHAKRABORTY[2], UNIVERSITY OF DELHI

Abstract

The mixed siliciclastic-carbonate system of Neoproterozoic Kurnool Group, India evokes interest for outcrop-based studies to frame a better understanding on the mechanism and control of its deposition. Narji Limestone Formation records a 250 m thick succession within the Kurnool Group. While documenting the underlying clastic Banganapalle Formation it was revealed that a concomitant rise in relative sea level turned the coastline from a clastic to a carbonate system. Carbonate platforms where in general dominated by ramp systems in Neoproterozoic timeframe. A rimmed platform geometry is visualised from documentation of reef, fore slope and shelf lagoon products from the Narji Formation. In contrast to Paleo- and Mesoproterozoic carbonate platforms where biohermal stromatolites dominate carbonate rimmed platforms in form of reefal structures, the Neoproterozoic carbonates are dominated by laminated microbialites, thrombolites and dendrolites.

Ten carbonate facies types were characterized and clubbed together under seven facies associations belonging to four different paleo-environmental settings viz. Forereef (intertidal to shallow subtidal and shallow to deep subtidal), peritidal reef and back-reef lagoon. Whereas crinkly microbial laminites with subordinate domal stromatolites constitute the reef part, the fore slope deposition in the platform largely remained tide-and storm-dominated. Grey to black colored pyrite bearing bedded limestone-shale alternation without any current or wave imprint represents the back-reef lagoon deposition. A high carbonate saturation and productivity in the Narji inner and mid shelf is suggested from an overall dominance of microalgal laminite and microdigitate stromatolites over columnar stromatolites. From documentation of decimeter-to meter-thick shallowing-upward depositional hemicycles, embedded within an overall aggradational Narji lithosuccession, a combined control of sea level and carbonate productivity is inferred in course of Narji sedimentation. It is suggested that a short-duration medium-to large-scale rise in the base level led to the aggradation in shallow water rim of the Narji platform margin; interruption of this overall motif by short thickening- and shallowing-upward progradational hemicycles bear testimony for higher productivity in the Narji mid-to inner shelf areas. The present study intends to correlate shallowing-upward hemicycles with keep-up to catch-up depositional cycles with signature of apparent sea level fall. The control of relative base level variation in Narji depositional history is strengthened with multiple signatures including secular δ13C composition, total organic carbon (TOC) content and siliciclastic content from the entire Narji litho-succession. Further, the secular δ13C signature, TOC value and siliciclastic content through the Narji succession allowed interpretation of open ocean circulation in the Narji carbonate platform and

roles of transgression and regression in framing the isotopic character of the Narji succession. It is proposed that higher saturation and productivity at times of transgression in the shelf resulted in local progradational stacking motif in Narji succession, which otherwise register aggradational stacking motif with near balance between subsidence and productivity.

Preliminary study on coupling between clinoform type and along-strike variability of shelf-edge stacking pattern

EUNHYUN CHO[1]*, Seoul National University (cho91@snu.ac.kr)
JUSUN WOO[2], Seoul National University

Abstract

In this study, we used 3D seismic data in the southwestern margin of the Ulleung Basin. The Middle Miocene clinoformal deposits were analyzed to assess the relationship between clinoform types and their spatial variation in shelf-edge stacking patterns. A total of 7 clinothems were recognized and classified into three types: 1. Sigmoidal, 2. Sigmoidal-Oblique, and 3. Oblique based on foreset configuration, lapout geometry and relative thickness of topeset and bottomset. The clinothems exhibited a cyclic stacking pattern, transitioning from sigmoidal to sigmoidal-oblique or oblique type. This cyclicity suggests the variations in accommodation conditions, with the sigmoidal type developed during relative sea-level highstand and sigmoidal-oblique and oblique type formed during relative sea-level lowstand. The sigmoidal clinothems were well-extended in all studied sections but were truncated in some parts, especially the south-eastern part of the study area. The sigmoidal-oblique type changes to oblique type along the strike. The oblique clinothems were recognized in south-eastern part of the study area, primarily resting on the truncated sigmoidal clinothem. Antithetic shelf-edge stacking patterns were perceived from sigmoidal and sigmoidal-oblique and oblique clinothem. Sigmoidal clinothems have higher progradation rates of shelf-edge in the north-western part, gradually decreasing towards the southeast. Conversely, sigmoidal-oblique and oblique clinothem show an inverse trend in shelf-edge growth, with higher progradation rates in the south-eastern part gradually decreasing towards the northwest.
This study introduces the antithetic along-strike variability of shelf-edge stacking patterns during relative sea-level highstand and lowstand.

Inefficient burial of terrestrial organic carbon in deltas

Yonggui YU[1]*, First Institute of Oceanography, Ministry of Natural Resources
(yuyonggui@fio.org.cn)

Abstract

The world's deltas are estimated to store ~58±17 Tg of terrestrial organic carbon (OCterr) annually, indicating their significant role in the global carbon cycle. However, these estimates are based on the proto burial efficiency (PBE) of OCterr in surface sediments of subaqueous deltas, which assumes that OCterr burial is spatially and temporally homogenous. Yet, the time-dependent OCterr burial and degradation in subaqueous delta deposit is poorly constrained due to the difficulty in determining the chronology of the deposits. By using a novel bathymetry-based method to date core sediments from the subaqueous Yellow River Delta (hereafter YRD), we show that the OCterr burial efficiencies in age-labeled deltaic sediments are highly heterogenous due to different sediment pathways and time-dependent OCterr degradation. River floods lead to an initial OCterr burial efficiency of up to ~62%±18% and negligible marine-derived OC in the flood deposits at the delta front. Subsequent sediment remobilization and early diagenesis, however, lead to substantial attachment of marine OC and degradation of OCterr, eventually resulting in different OC compositions and lower burial efficiencies ranging from 36%±12% to 57%±10%. Despite the refractory nature of OCterr, the post-burial OCterr degradation rate is estimated to be 0.7% per year, further lowering the initial OCterr burial efficiency to ~36% after 56 years. Our multi-decadal net OCterr burial efficiency is at least 50% lower than previous PBE-derived estimates from the YRD. This pattern likely extends to deltas globally, calling for a re-assessment of river delta influence in the global carbon cycle.

Development of submarine canyon from East Brazilian Passive Continental Margin

Daniela de Andrade MOREIRA[1]*, University of Rio Grande do Norte (daniandrade.m@gmail.com)
Helenice Vital[2], Federal University of Rio Grande do Norte, Postgraduate Program in Geodynamics and Geophysics (PPGG), Brazil

Abstract

The formation and development of submarine canyons can record geological information about the regional sea-level, climate change, ancient deep-sea sedimentary process and tectonic activities. Some studies revealed erosive turbidity currents can drive their development by reworking the canyon's shapes. The purpose of this study is to comprehend the sedimentary processes involved in the genesis of submarine canyons in East Brazilian Passive Continental Margin. The methodological approach includes seabed mapping with multibeam bathymetry – MB and sub-bottom profiles – SBP. The results show that the canyon displays notable prominence and It's indented on the shelf edge. Exhibit high continuity and high sinuosity near the shelf edge, transitioning to an approximately straight basinward. In addition, it begins with a dendritic pattern and shows terraces near it. The thalweg undergoes variations as, initially on the canyon head, the depth is shallower, ranging from ~450-750 m and deep as basinward, reaching up to ~2.000 m in depth. The width ranges from ~1.000 m wide and widens as the depth increases towards the basin, reaching up to ~4.000 m. The length extends up to ~12 km. These are evidence that it has been shaped by erosive flow possibly due the close association with fluvial continental sources and can be regarded as a sediment conduit the shelf to the deep basin. Moreover, turbidity currents can act as the driving force, reshaping and resulting in the current canyon morphology. Also, due this region has no tectonic prominent scope, the development of this canyon could be especially controlled by sedimentary processes. It's essential to categorize features in this region to comprehend their stability since the successful implementation of offshore structures depends on a thorough understanding. This sector is gaining significance amidst the global energy transition. In addition, this scientific outcome contributes to advancing the goals of the United Nations' Ocean Decade initiative.

with experts from various fields of science, which is the basis of research in this field. Training of a new generation of scholars in Africa, can have several socio-economic benefits, including understanding of the causes as well as therapy for many common health issues. Identification of the geological sources of toxic and potentially harmful elements and minerals in the environment, which are transferred to human/animals body through water, air and food, and identification of areas lacking essential elements for a healthy living, are necessary to reduce the health impacts caused by such anomalies and ensure wellbeing. The identification of such geo-anomalies and related health issues is followed by the development of geospatial distribution modelling and techniques for the prediction of their occurrences and removal. Furthermore, the continuous demand of safe and adequate water and energy supply in Africa grows due to population increase on the continent. Consequently, communities especially in rural areas often consider unsafe alternatives (uncontrolled water sources and burning coal for daily consumption) which often contain high concentrations of toxic and/or potentially harmful elements/minerals. The naturally hidden occurrences of such elements and minerals can have serious short and/or long-term health impacts. Therefore, the assessment of the nature and composition of these commodities is necessary to prevent the health damage and to create a safer living environment for the communities.

Deep-water sedimentation controlled by interaction between bottom current and gravity flow: A case study of Rovuma Basin, East Africa

Jianan WU[1]*, Petrochina Hangzhou Research Institute of Geology (642837124@qq.com)
Guoping Zuo[2], PetroChina Hangzhou Research Institute of Geology
Guozhang Fan[3], PetroChina Hangzhou Research Institute of Geology

Abstract

As the main depositional process that transports terrigenous material into deep-water areas, turbidity flows are commonly the focus of deep-water sedimentology. However, increasingly, studies are showing that bottom currents also play important roles in deep-water terrigenous deposition.

By using 3D seismic dataset recently acquired in offshore Mozambique, we address the distribution pattern of a Cenozoic channel-levee-lobe complex in deep-water of Rovuma Basin. The results show that the unique levee of this complex asymmetrically developed only on one side of the channel course. We attribute this asymmetric levee development to the interaction between the western slope bottom current from south to north and the gravity flow from west down slope. Due to the winnowing and sorting by the western slope bottom current, the sorted fine grain sediments of the gravity flow were blown and deposited to aside remaining clean sand from the gravity flow deposited within the channel. The lateral deposits steepened northern channel banks and forced the southward migration of channel axes.

On the other hand, reservoir quality variations for 5 main lithofacies have been analyzed combined with core and well-log data. Some medium- to coarse-grained sandstone cores with parallel- to cross-stratification show higher permeability compared to the massive ones, which may imply the existence of bottom current can develop laminated sandstones and improve the reservoir quality.

Li isotopic behaviors of particulate and dissolved load in the Changjiang (Yangtze River) Estuary

Chengfan YANG[1]*, Tongji University (cfyang@tongji.edu.cn)
Shouye Yang[2], Tongji University

Abstract

Chemical weathering plays an important role in regulating biogeochemical cycle and global climate. Based on the high-resolution sedimentary records, numerous studies on paleo-environment reconstruction have been carried out in the continental margin. However, several lines of evidence have confirmed the alteration of elemental composition during materials passing through the estuary. How weathering signal responds to river and sea water mixing is still debated. Thus, the geochemical behaviors of particulate and dissolved load in the estuary need to be further investigated. In this study, suspended particulate matter (SPM) and dissolved load were collected in the Changjiang (Yangtze River) Estuary, and their elemental and Li isotopic compositions were analyzed.

Results show a conservative mixing of dissolved Li and its isotopes between the Changjiang River water and seawater. The dissolved δ7Li yields a non-linear increase with salinity, and a significant increase occurs during the initial water mixing. In order to verify this conservative phenomenon, a sequential leaching method was performed on SPM samples. We find that Fe-Mn oxyhydroxide is the largest reservoir of non-silicate Li, accounting for ~5% of Li in bulk SPM samples. However, possibly due to short interaction time during SPM passing through the estuary, incorporation of Li into non-silicate phases cannot drive a detectable alteration of estuarine dissolved Li concentration. Scavenging processes thus have negligible influence on aqueous Li behavior, at least in the Changjiang-like basins and estuaries, which verifies the assumption of a conservative behavior for using Li isotopes in marine authigenic archives to reconstruct past continental weathering variations and related carbon cycles

Through the studied transect, estuarine flocculation and resuspension processes cause the homogenization of offshore particulate δ7Li that is close to the average composition of upper continental crust. This process is distinct from the general control of hydrodynamic sorting on elemental geochemical compositions during river sediment source-to-sink transport. The indication of detrital δ7Li for tracing past continental weathering in the coastal and marginal seas seems to be more complicated relative to dissolved phase. Caution should then be taken when using δ7Li, and other similar sediment geochemical proxies, measured in bulk sediments from marginal seas to reconstruct past continental weathering.

Stratigraphic architecture of the Morondava Basin (western margin of Madagascar): geo-acoustic quantification from high-resolution multi-trace seismic data

Dhishna BULJORE[1]*, Ifremer (dhishna.buljore@ifremer.fr)

Abstract

The Morondava Basin is situated to the east of the Mozambique Channel and to the west of the Madagascan margin. It was formed during the Jurassic period due to the separation of Madagascar and East Africa along the Davie transform ridge. The basin accumulated sedimentary deposits from the Toarcian to the Pleistocene, originating from Madagascar and Juan de Nova. The sediment organisation have been little documented by academic studies and the objective of this study is to detail the stratigraphic pattern of this sedimentary basin and the geo-acoustic properties of the stacked sequences.

The Shom conducted the SOUSACOUS2021 campaign using high-resolution seismic imaging to describe the sedimentary architecture of the deposits from the Upper Cretaceous to the Pleistocene. The sequential analysis of stratigraphy was achieved by describing seismic facies and discontinuities. The sequences' interval velocities were quantified using RMS velocities (Vel_Analysis, Ifremer).

The stratigraphy successions in the Morondava Basin recorded major changes in the depositional processes and the sediment fluxes. It reveals sharp evolutions through the Cenozoic of the deep ocean circulation in the Mozambique Channel and the close link between geomorphological changes in Madagascar and the sedimentary deposits in the Morondava Basin. The basin is divided into two sub-basins by a North-South central tectonic-sedimentary ridge, which constrains the gravitational (MTD) sediments in the east and the dominant hemipelagic sedimentation in the west. In the Paleogene, this paleo-morphology favoured the establishment of two contourite systems: one in the deep basin (to the west of the central ridge) and the other in the Juan de Nova basin (to the east of the central ridge). This setting suggests a more intense deep-sea circulation and bottom currents flowing from south to north (Southern Component Water - SCW) during the Paleogene. The Neogene deposits document the events linked to the evolution of continental geomorphology of Madagascar and the consequent changes in catchment areas. The sedimentary deposits reveal the significant tectonic and paleogeographic changes driving the continental alteration and sediment production.

The main stratigraphic boundaries are also distinguished by variations in acoustic wave propagation velocities at the transition of the major seismic facies in the Morondava Basin. The decrease in interval velocities towards the western part of the Morondava basin seems to be closely linked to the nature and processes of sedimentary input into the deep basin. Higher

propagation velocities are observed in carbonate-rich MTDs, whereas hemipelagic sediments exhibit lower velocities. The increasing variations in velocity with depth are related to the increasing compaction of the sedimentary column.
This study enhances comprehension of the sedimentary deposits' architecture, provides a quantified characterisation of the seabed's geo-acoustic properties and a more accurate estimate of the thickness of the different stratigraphic sequences deposited in the Morondava basin since the Cretaceous.

Lacustrine environment evolution in the Mesozoic North Yellow Sea Basin, Eastern China: insight from the transition of Jurassic grey mudstones to Cretaceous red successions

REN WANG[1]*, China University of Geosciences (rwang@cug.edu.cn)

Abstract

During the Cretaceous period, terrestrial red beds emerged in various global regions. Previous reports have suggested that these red beds may be intricately linked to hot paleoclimates and unique paleogeographic configurations. This study focuses on petrological, mineralogical, and geochemical analyses conducted on samples from grey to red successions dating from the Middle Jurassic to Early Cretaceous within the North Yellow Sea Basin, to investigate the evolution of lacustrine environments and paleoclimates during their deposition. Some mudstone samples have identified positive Eu anomalies, but the hydrothermal signal may not be as strong due to the open lake environment. The findings revealed four episodes of hydrothermal activity occurring during the deposition of Jurassic grey mudstone to the Cretaceous red successions. Hf vs La/Th and ∑REE vs La/Yb graphs indicate that most grey mudstones originate primarily from upper crustal felsic sources, while certain red mudstones contain mantle material. Analytical diagrams such as Th-Co-Zr/10, Th-Sc-Zr/10, and La-Th-Sc suggest the presence of active continental margins and island arcs, showing analogous characteristics in REEs distribution patterns. Noteworthy indicators like Sr/Ba, B/Ga, U/Th, Ni/Co, V/Cr and V/(V+Ni) values denote that the sedimentary environments of both grey and red mudstones were oxidized, deviating from conventional viewpoints. However, this deviation may stem from hydrothermal contamination impacting trace elements such as Ni, Co, and Sr. Assessment using indicators like ICV and CIA reflects a transition from a warm and wet Jurassic climate to a hot Early Cretaceous climate. Variations in lake levels, prompted by climate fluctuations, led to increased oxygenation at the lake bottom, resulting in the deposition of red mudstone. These findings suggest a close correlation between the red mudstones and the hot climate driven by tectonic evolution of Eastern China. The transformation from grey to red mudstones during the Middle Jurassic to Early Cretaceous period signifies a response to paleoclimatic and paleoenvironmental changes.

An improved FT-TRA system and its application to element analysis of sediments and foraminifera

Juan XU[1]*, Tongji University (juanxu@tongji.edu.cn)
Shouye Yang[2], Tongji University

Abstract

In recent decays, various sequential leaching procedures targeting the element budgets associated with different fractions of the mixed sediments, were proposed in environmental and sedimentary geochemical studies. Also, elements and isotopes of foraminiferal shells are potentially valuable paleo-proxy for paleoceanography research. The standard hand-on batch method for elemental and isotopic analysis often results in substantial loss of sample, as well as contamination by secondary calcite and clay, thus biasing the data toward a more variable and anomalous result. These potentially significant sources of error can be overcome with a flow-through time-resolved (FT-TRA) sequential leaching method that makes time- and labor-intensive pretreatments unnecessary. Moreover, the detailed elemental composition during the whole leaching process can be documented and retrieved from the time series data when using FT-TRA analysis. In this study, we developed an accessible, multi-faced FT-TRA module which allows a wide variety of applications can be developed, by customizing key system parameters such as sample cell types (volumes varying from 25 µL to 50 mL). It also offers the choice between on-line analysis or fraction collection for off-line. To verify the reliability and accuracy of our FT-TRA system, systematic analysis was carried out, including dissolution of foraminifera and sediment standard samples. Comparing FT-TRA and laser ablation measurements of cleaned foraminifer shells indicate that, while thorough manual cleaning can remove adhering clay minerals, it cannot effectively remove Fe-Mn oxides or Mn-carbonates incrustations. FT-TRA is thus preferable to LA-ICPMS because it does not rely on questionable cleaning procedures.

An improved understanding of the magnetic proxies of marine sediment in the South China Sea

Meinan SHI[1]*, China University of Geosciences, Beijing 100083, China (beijiying@foxmail.com)

Abstract

The magnetism research of South China Sea (SCS) sediments and surrounding rivers have significantly improved over the past decade, vigorously promoting the understanding of the environmental development of the SCS and reconstruction of the history of the orbital-scale East Asian monsoon evolution. Studies have revealed that magnetic minerals of sediment source in the northwestern part of SCS is dominanted by coarse magnetite, while fine grain magnetite containing variable amounts of hematite is mainly magnetic mineral in southern SCS. The variation in magnetic characterization of sediments in the SCS results from an interplay of provance, transport path and transport efficency which in turn depends on change in sea level and oceanic circultions, evolution of global climate and East Asian monsoon and regional tectonic activity However, the interpretation of paleoclimatic implications of magnetic parameters obtianed from the SCS marine sediments can be complex and ambiguous, which are attributed to the specific enivormental quantificial meaning and the complexd environmental in south China sea. This study provides insights into the long-term variation of magnetic fraction cored from ODP Sites 1143, 1148 and IODP Sites U1501 drilled in the South China Sea, and IODP Site C0011 in the Shikoku Basin, and pay attention to whether the responses of magnetic indicators are consistent in north-south SCS and how they respond to environmental changes. This work suggests that variation of magnetic parameters of SCS marine sediment respond differently to the environmental process on the long-term time scale. The concentration of magnetic particle is related to detrial input associated with East Asian monsoon, while the magnetic mineralogical composition and grain size are mainly related to provenance associated with oceanic circulation on glacial/interglacial timescale.

Paleoenvironmental reconstruction of the Colombian Maastrichtian Coals: Insights from facies analysis and coal petrology. Northern Andes

JUAN SEBASTIAN GOMEZ NEITA[1]*, UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL (juan.gomezneita@uptc.edu.co)
Ana Maria Mizusaki[2], UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL
Tais Freitas[3], UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL
Sandra Rocio Manosalva[4], UNIVERSIDAD PEDAGÓGICA Y TECNOLÓGICA DE COLOMBIA

Abstract

Understanding the paleoenvironmental conditions during the final phase of the Cretaceous period in Colombia is essential for unraveling the Eastern Cordillera Basin geological history and its impact on coal formation processes. This study employs sedimentary facies analysis and coal petrology to elucidate the paleoenvironmental settings of Maastrichtian coals from the Guaduas Formation in the Colombian Andes. In this way, our results offer valuable insights into ancient ecosystems and depositional environments in response to sea level fluctuations, sediment input, and kind of vegetation. The primary purpose of this research is to reconstruct the depositional systems that influenced the accumulation of terrestrial-derived organic matter during the Maastrichtian period in the Checua-Lenguazaque Syncline coal-bearing. Maceral and microlithotypes analysis, combined with sedimentological characteristics, provides a detailed understanding of changes in the depositional processes. Furthermore, coal petrology offers crucial information regarding organic matter composition, allowing for a comprehensive assessment of coal formation dynamics.

Results from facies analysis reveal a diverse range of depositional systems such as lagoon, tidal flat, delta plain, and fluvial settings indicative of fluctuating environmental conditions along the Guaduas Formation. Variations in the maceral composition suggest changes in water depth, kind of vegetation, oxidation, and accommodation during time. The coal composition indicates dominance in macerals of the vitrinite group followed by macerals of the inertinite group, which indicates periods of oxidation related mainly to subareal exposure and forest fires. According to the petrographic indices (TPI, GI, VI, and GWI), coals from the Guaduas Formation originated from reed and forest communities on limno-telmatic to telmatic conditions. The terrestrial organic matter was accumulated in mesotrophic to ombrotrophic paleomires. The restriction of the peats from groundwater circulation explains the low ash field of these coals. The occurrence of pyrite (>1.5%) indicates the influence of marine waters, confirming the coastal setting of the Guaduas Formation. Microlithotypes of these coals are represented mainly by vitrite and vitrinertite which suggests deposition in fluvial to deltaic settings.

Conclusions drawn from this study highlight the significance of facies analysis and coal petrology in reconstructing paleoenvironmental conditions during the upper Maastrichtian in the Colombian Andes. The integration of sedimentological and petrological data provides a robust framework for

understanding coal formation processes and environmental dynamics in coastal settings. These findings contribute to our broader understanding of ancient ecosystems and serve as valuable insights for geological and paleoenvironmental studies in the most representative bituminous coal bearing in South America (Checua-Lenguazaque Syncline). In summary, the combined approach of facies analysis and coal petrology offers a holistic understanding of changes in paleoenvironments from tidal flats to fluvial settings in response to a main regressive process in the basin. This research not only enhances our knowledge of past environments but also provides critical information for resource exploration and environmental management in coal-bearing regions.

Abstract

In continental oil and gas basins, unconventional resources such as shale oil and tight oil are extensively distributed. The sweet spots in unconventional oil and gas resources are highly coupled with frequent global or regional geological events that occurred during various geological historical periods. Deep hydrothermal activity, as a typical geological event, significantly influences the enrichment of organic matter. This study focuses on the Paleogene Shahejie Formation in the miaoxi Sag of the Bohai Bay Basin. It elucidates the geochemical characteristics of source rocks in the area, reconstructs the water medium conditions and hydrothermal activities of different geological periods, and reveals the mechanism of organic matter enrichment influenced by hydrothermal activity.

The analysis of rock pyrolysis and vitrinite reflectance (Ro) data reveals significant differences in the geochemical characteristics among hydrocarbon source rocks from different interval. The organic matter in the hydrocarbon source rocks of the fourth member of Shahejie Formation(E2s4) is primarily of type II1, with a relatively low organic abundance, averaging at 0.5%.The organic matter in the hydrocarbon source rocks of the first to second members of Shahejie FormationE3s1-2and the third member of the Shahejie FormationE2s3 is predominantly of Type I, with higher organic abundance, averaging 2.61% and 1.96% respectively. Overall, the vitrinite reflectance (Ro) values range between 0.31% and 0.7%, indicating that the rocks are in a low maturity stage.

The analysis of trace elements, biomarkers, and paleontological data indicates that with the intensification of hydrothermal activity, total organic carbon (TOC) ,Corg: P, Ph/Pr and Gammacerane Index (GI) all exhibit a trend of increasing first and then decreasing, with a critical value around $\delta Eu = 4$. When $\delta Eu<4$, the nutrients brought by deep hydrothermal upwelling promotes the algae blooms, leading to a rapid increase in paleo-productivity. Simultaneously, the reducing conditions in the bottom water gradually intensify, resulting in a gradual increase in TOC. However, when $\delta Eu>4$, the continuous enhancement of hydrothermal activity brings a significant amount of salt substances. As a result, the population of organisms in the basin rapidly decreases, and the curve depicting the changes in paleo-productivity gradually levels off. In addition, the intense eruption of hydrothermal fluids disrupted the stable stratification of the water column, leading to increased oxygen dissolution and extensive degradation of OM, resulting in a gradual decrease in TOC.

In summary, during the deposition period of the Es4, the preservation conditions crucial for

organic matter enrichment are primarily influenced by the dominant role of intense hydrothermal activity. During the deposition period from the E2s3 to the E3s1-2, the main controlling factors for the enrichment of organic matter in hydrocarbon source rocks are the preservation conditions characterized by moderate hydrothermal activity, high productivity, and reduced oxygen levels. This study not only contributes to the further refinement of organic matter enrichment theories but also holds valuable insights for the study of dominant hydrocarbon-producing biological species in different aquatic environments.

Evolution of a small forarc basin associated with the change in the plate motion: an example of the Pliocene Kakegawa Group central Japan

HARUKI SONE[1]*, Nippon koei L.t.d (tanjou@outlook.jp)
TETSUYA SAKAI[2], Department of Geoscience, Shimane University

Abstract

This study investigates the evolutionary dynamics of the early forearc basin (Kakegawa Basin) by analyzing turbidite characteristics within the lower section of the Plio-Pleistocene Kakegawa Group (approximately 4.0 – 1.0 Ma). Situated near the arc-arc collision zone of the Honshu and Izu-Bonin arcs, and adjacent to the present subduction zone (Suruga Trough) in central Japan, the Kakegawa Basin likely experienced significant tectonic events such as the collision of a northward-migrating island (present-day Izu Peninsula) and a shift in the motion of the Philippine Sea Plate around 3.0 Ma. Our detailed analysis of paleoflow and paleoslope directions within fine-grained turbidites of the lower Kakeagwa Group has allowed for the reconstruction of basin morphology, even along the sections normal to the dominant paleoflow trend.

Within the southeastern distal margin of the basin fill, three distinct units were identified within the lower part of the group (Horinouchi Formation) based on paleoflow and paleoslope directions. These units unconformably overlay Mio-Pliocene forearc basin fill (Sagara Group), which inclines towards the northwest at an angle of approximately 60°. Unit 1 (3.8-2.9 Ma) exhibits dominant paleoflows towards the east (offshore-ward), indicating the presence of an east-dipping trough within the basin. Unit 2 (2.9-2.6 Ma) likely onlaps Unit 1 in the southern region, displaying similar paleoflow and paleoslope patterns. Unit 3 (2.6-2.5 Ma) shows turbidites with characteristics of reflected currents, suggesting paleoflows in both east and west directions, indicative of outer ridge upbuilding preceding its deposition.

Our analysis reveals an east-west trending basin with its outer ridge located to the south, subjected to westward tilting of the basin. The presence of an east-west trending trough before 4 Ma aligns with the northward subducting Philippine Sea Plate. The subsequent uplift of a new outer ridge to the east of the basin may be attributed to the northwestward motion of the Philippine Sea Plate and the migration of the proto-Izu Peninsula, possibly inducing east-west or northwest-southeast compression within the basin.

Sedimentary facies and evolution of fluvio-estuarine depositional system during late Pleistocene to Holocene in the Nakdong valley, southeastern Korea

Seok-Hwi HONG[1]*, Korea Institute of Geoscience and Mineral Resources (shhong@kigam.re.kr)
Woo Hun Ryang[2], Jeonbuk National University
Dong-Geun Yoo[3], Korea Institute of Geoscience and Mineral Resources
Jin Cheul Kim[4], Korea Institute of Geoscience and Mineral Resources
Gwang-Soo Lee[5], Korea Institute of Geoscience and Mineral Resources

Abstract

Evolutions of transition zones between fluvial and marine systems were recorded in the Nakdong valley fills in response to relative sea-level changes. We aquired five cores in the Nakdong valley fills consisting of late Pleistocene to Holocene deposits. Sixteen facies are defined and grouped into eight facies association; alluvial plain, fluvial channel and floodplain, oxidized fluvial channel, tidal flat, tidal bar, central basin and bayhead prodelta, bayhead delta front, and bayhead delta plain. The associations are compiled up three depositional units in the Nakdong valley fills. Unit 1 consists of alluvial plain and fluvial channel in the lowermost part of cores. Unit 2 contains tidal flats, tidal bars, and central basin in an estuary system adjacent to Unit 1. The topmost Unit 3 is bayhead delta deposits consisting of bayhead delta plain, bayhead delta front, and bayhead prodelta after the depositions of Unit 2. The sequence stratigraphy of the Nakdong valley fills can be divided into three systems tract; a lowstand systems tract (LST), a transgressive systems tract (TST), and highstand systems tract (HST). Synthesization of sixteen sedimentary facies, eight facies associations, 833 sediment textures, and 118 age data propose six depositional stages of the developing Nakdong fully filled bayhead delta. The depositional model is able to output the reconstruction of relative sea-level (RSL) rise in the Nakdong valley after 12 ka during the early to late Holocene.

Abstract

Sediment source-sink process of the mega rivers has been a key research subject. It is always a challenge to develop robust fingerprints for large river sediment routing systems due to the complexity of geological, geomorphological and hydrodynamic characteristics of the river basins, which result in mixing and overprinting of raw source signals. The Yellow River or Huang He, one of the most sediment-laden rivers on Earth, pumps tremendous amounts of debris from the Asian continent to the marginal seas. In the middle reaches of the Yellow River, where the fluvial system encounters an aeolian system, formed and shaped the famous Chinese Loess Plateau (CLP), making the Yellow River a unique river system among the other global mega rivers. Here we provide a comprehensive sediment source-sink study of the modern Yellow River sand based on provenance analysis of detrital rutile trace element composition and U-Pb ages. We collected modern riverbank samples both from the trunk (from its headwaters in the Tibetan Plateau to the river estuary) and main tributaries of the river basins. Our sampling also included aeolian sediment from the CLP and marine sediment from the East Asian marginal seas of Bohai Sea and Yellow Sea. An extensive dataset of detrital rutile trace elements and U-Pb ages were generated by in-situ LA-ICP-MS analysis of the representative samples. The main objectives of this study are 1) to establish source signatures of different reaches of the river based on the coupled information of the rutile trace elements and U-Pb ages, 2) to investigate the effect of erosion and hydrodynamic sorting on grain size and further impact on the distribution of rutile U-Pb ages and trace elements, 3) to untangle the source-sink relationship of the aeolian sediment and fluvial sediment in the middle reaches of the Yellow River. The outcome of this study would provide insights into understanding the sediment transport process of the large river system, the interaction between aeolian and fluvial system, and sedimentary process in the continental margin.

Continental crustal evolution revealed through sedimentary rocks: a case study from India

ESHA RAY[1]*, PhD (eshaiitk@gmail.com)
DEBAJYOTI PAUL[2], PhD
RAJNEESH BHUTANI[3], PhD
RAMANANDA CHAKRABARTI[4], PhD
SHOUYE YANG[5], PhD

Abstract

Sedimentary rocks (primarily shale and sandstone) consist of ~10% of the overall mass of the continental crust. Therefore, the chemical composition of the fine-grained terrigenous clastic sedimentary rocks represent the exposed part of the upper continental crust (UCC). Therefore, the Nd isotopic compositions of sediments can be used as a reliable proxy for provenance. Therefore, by selecting and analyzing sedimentary rock, particularly shales, from various basins covering a wide range of geological time, it is possible to use the τDM of shale samples to determine the growth pattern of the continental crust.

This study reports the Sm-Nd isotopic composition of Indian shale samples (n = 54) ranging from Archean to Recent age, collected and compiled from different litho-units of Archean cratons and Proterozoic basins. Using the isotope data, we calculated the Nd model ages of these shales and estimated the growth rate of the Indian continental crust. Present-day average 143Nd/144Nd (0.51170 ± 0.00028; εNd(0) = –18.8 ± 5.4) and 147Sm/144Nd (0.111 ± 0.009) isotopic ratios of Indian shales (this study) are comparable to those of average global clastic sediments (primarily shales), North American shales, and sediments from the Ganga River. but exhibit slight differences compared to those of the Upper Continental Crust (UCC), loess, and average river/aeolian particulates in terms of Nd isotopic composition (with εNd(0) approximately –10), despite having similar Sm/Nd ratios ranging from 0.17 to 0.19. The remarkable similarity of Sm/Nd ratios and 143Nd/144Nd in present-day UCC-derived erosional products like the Ganga River sediments, implies that the isotopic compositions of average Indian shale might be representative of Indian UCC. Finally, we used a two-stage box model approach (dividing the crust into juvenile and older shield areas) to model the growth of the Indian continental crust from Hadean to Recent using a dimensionless erosional parameter K which accounts for the effect of preferential erosion. In our model, we assumed K = 1 for the Archean (no erosion) and K = 6 for the post-Archean to Recent. The model result suggests that the ~80% of the continental crust was formed by the end of Archean (with mean age of the continent of 2.42 Ga). This study represents a first-ever estimate of the growth rate of the entire Indian shield and indicates a rapid growth of the Indian continental crust in the Archean period, followed by a long-term slow-progressive growth in the post-Archean which can be modulated by the supercontinent cycles and mantle plume activities. Unfortunately, this model fails to predict the amount of crustal recycling through time. Therefore, for future research, new approach should be adopted which can forecast the volume of

continental crust being destroyed and recycled back both at present and back in time into the mantle to represent variations in the mantle chemistry.

Isotopic fingerprinting of benthic dissolved iron cycling and iron sources in the Changjiang Estuary

Zhiwei HE[1]*, Tongji University (hezw@tongji.edu.cn)
Min Zheng[2], Tongji University
Shouye Yang[3], Tongji University

Abstract

The Changjiang Estuary, an active zone of land-sea interaction influenced by a large river, is a key representative in the study of global source-to-sink systems. Iron (Fe), the most abundant redox-sensitive metal in the Earth's crust and an essential micronutrient for marine primary production, plays a critical role in the early diagenetic cycle. This cycle significantly influences the migration and transformation of biogenic elements in estuaries, the burial and remineralization of organic carbon, as well as the geochemical behavior of various trace elements.

This study reports on the depth and spatial distribution characteristics of sediment and porewater Fe isotope compositions and related geochemical parameters at six stations in the Changjiang Estuary. The results show that the total organic carbon (TOC) content in the sediments is generally low (~0.1 to 0.7 wt%), with variations with depth reflecting different degrees of organic matter degradation during the early diagenetic process. The Fe/Al ratios in sediments from different stations are similar and close to the average value of the continental crust. The speciation of iron in the sediments indicates that the muddy area of the Changjiang Estuary is conducive to dissimilatory Fe reduction. The whole-rock Fe isotope composition (δ^{56}Fe = -0.1‰ to 0.1‰) in the sediments is also close to the average value of the continental crust, suggesting that despite the migration and transformation of Fe during the early diagenetic process, the variation in the solid-phase Fe isotope characteristics of the sediments is not significant. This is mainly because the sediments in the Changjiang Estuary receive a large amount of terrigenous detrital material carried by the Changjiang River, which weakens the impact of the early diagenetic process on the sediment Fe isotope composition.

Conversely, some sediment porewaters show significant variations in dissolved Fe concentrations (~1-200 μmol L-1) and isotopic compositions (δ^{56}Fe = -2‰ to 1‰). The profile variations of porewater Fe content and δ^{56}Fe indicate that Fe isotopes can sensitively trace different diagenetic cycling paths of Fe, such as dissimilatory Fe reduction and bacterial sulfate reduction, and precipitation of iron sulfides and oxides, during the early diagenetic process, and can be quantitatively reproduced through a reaction-transport model. Further studies show that the Fe flux and δ^{56}Fe characteristics at the sediment-water interface, obtained by the ^{224}Ra/^{228}Th disequilibrium method, are mainly controlled by the dissolved oxygen concentration in the bottom water. Nonetheless, the Fe released from the sediments of the Changjiang Estuary into the water body is primarily characterized by light Fe isotopes (δ^{56}Fe < 0‰), indicating the influence of dissimilatory Fe reduction. This work is of great significance for identifying the isotopic characteristics of dissolved Fe in different sedimentary environments of estuaries and their

contributions to seawater dissolved Fe, as well as for deepening our understanding of the source-to-sink patterns of Fe in the global ocean.

Abstract

Submarine canyons are important channels for sediment transport on the continental slope and are also key locations for the accumulation of gas hydrates and shallow gas. Understanding the evolution of submarine canyons and the fluids containing gas is crucial. In this study, we integrated high-resolution bathymetry, seismic data, as well as log and lithologic data to examine the shape and filling of submarine canyons in the Qiongdongnan Basin. We also illustrated the distribution of gas chimneys and bottom simulating reflectors in this area. Moreover, the stacking patterns, formation and evolution of these submarine canyons, gas hydrate accumulation, and their interaction between the canyon development and gas hydrate accumulation are discussed. The results show that there are five NW-SE oriented slope-confined submarine canyons in the study area, ranging in water depth from 300 m to 1700 m. The filling deposits of these canyons can be categorized into five types: turbidity-dominated muddy deposits (Seismic facies A), mass transport deposits (Seismic facies B), slumps (Seismic facies C), slides (Seismic facies D), and bottom current-dominated muddy deposits (Seismic facies E). Significant gas chimneys and bottom simulating reflectors are mainly located in the ridge strata of the canyons. These submarine canyons have been developing since approximately 5.5 Ma and NE migrated. Their development can be divided into three stages: primary turbidite channels, linear canyons, and dendritic canyons. Gravity flow activity and continuous bottom currents play important roles in the evolution of the canyons. Gas hydrate accumulation is associated with both thermogenic and biogenic gases, with deep faults and gas chimneys serving as the main migration pathways. The evolution of the canyons is closely linked to the accumulation and decomposition of hydrates. Multiple stages of mass transport deposits control the formation and accumulation of gas hydrates within the submarine canyon ridges. Additionally, hydrates located in the upper layer are prone to decomposition, which promotes the dendritic development of the upper segments of these canyons.

Hui Sun[5], CNOOC (China) Co., Ltd. Shenzhen Branch

Abstract

In recent years, the Baiyun Seg has revealed significant exploration potential in exploration and development. However, due to the limitations of sparse drilling exposure and low seismic resolution in the deep Enping Formation, there is a lack of understanding of the sequence stratigraphic division and source-to-sink system characteristics of the Enping Formation, severely constraining further oil and gas exploration and development deployment in the Baiyun Seg. By applying 3D seismic, drilling data, and zircon dating, and in conjunction with regional tectonic evolution characteristics, this study analyzes the Baiyun Seg's Enping Formation material source system and sediment dispersal system from the perspective of source-to-sink system research, guided by sequence stratigraphy and seismic sedimentology theories. It clarifies the formation and sourcing action of the material source, ancient geomorphology and valley transport systems, sedimentary outcomes and distributions, and the coupling relationship between source-to-sink systems.

The main achievements of this thesis are as follows:1)The Enping Formation can be divided into three third-order sequences from top to bottom: EPSQ4+3 (Enping Sections 1 and 2), EPSQ2 (Enping Section 3), and EPSQ1 (Enping Section 4)2)The tectonic environment of the material source area during the Enping Formation's depositional period was a passive continental margin arc. The material source areas were the peripheral Panyu Low Uplift, Yunli Low Uplift, and Baiyun East Low Bulge, showing characteristics of proximal deposition. The overall lithology of the material source areas was mainly mature continental quartz, with the material source areas overall experiencing moderate weathering intensity3)The Baiyun Seg's Enping Formation depositional period mainly developed braided river deltas. Based on the depositional characteristics of the braided river delta, it can be divided into three sub-facies: braided river delta plain, braided river delta front, and pro-delta of the braided river4)Through the coupling of ancient geomorphology and the Enping Formation's source-to-sink system, four proximal material source systems developed in the Enping Formation: Panyu, Yunli Low Uplift, Yun East Low Bulge, and Yunkai Low Bulge. During the deposition of the Enping Section 4, the Baiyun Seg was in the late stage of rifting (i.e., Rifting II stage). A proximal-gentle slope-shallow water source-to-sink system developed on the southern slope of the eastern part of the Panyu Low Uplift, using ancient valleys as transport channels, forming a medium-sized braided river delta in the sedimentary convergence area. A small-scale proximal-gentle slope-shallow water source-to-sink system

developed in the Liuhua area in the northern part of the Baiyun East Low Bulge, depositing a small-scale braided river delta5)This paper establishes three stages of source-to-sink coupling models for the Paleogene Enping Formation in the Baiyun Seg: distal-gentle slope-shallow water, proximal-gentle slope-shallow water, and proximal-steep slope-deep water source-to-sink system types. It provides a reservoir prediction basis for subsequent deepwater deep natural gas exploration.

Abstract

The Tagling Formation is widely spread along the Tethyan Himalaya, from Hazara basin of Pakistan in the North-west to Nepal in South-east, and is Rhaetian to Lower Jurassic in age. A study of its section from the Spiti Valley reveals that it is dominated by limestones and dolostones with its top being characterized by at least one hardground surface with bivalve borings and encrusting oysters pointing to a pronounced gap in sedimentation. Quantitative analysis was carried out on the thin sections for microfacies identification, which resulted in establishing the facies change in the limestone including mudstone facies, wackestone facies, grainstone facies and packstone facies indicating changes in the depositional environment from storm-dominating offshore environment to calm and low energy environment setting and many in between. Thin-section studies also advocate for burrow-selective dolomitization at multiple levels in the TST. In the HST, in contrast, dolomitization is only sporadic and represents a mix of matrix and burrow types. Thin-bedded units rich in fossils characterize the transgressive systems tract (TST) with the top of the bed being highly bioturbated with Balanoglossites suggesting firm-ground conditions. The occurrence of Ferruginous Oolite Formation and the subsequent Spiti shale Formation after the Tagling Formation is no coincidence as carbonate platforms throughout the world has seen similar facies change about the early Toarcian Oceanic Anoxic event (TOAE).

Fine-grained turbidites in the southern Okinawa Trough and its implication for earthquakes activity over the past 700 years

Yang YAMIN[1]*, China Geological Survey Natural Resources Comprehensive Survey Command Center (yangyamin@mail.cgs.gov.cn)

Abstract

Understanding recurrence intervals of earthquakes is an essential prerequisite for improving seismic hazard assessment (Moernaut et al., 2018; Satake and Atwater, 2007). Due to the short time span of earthquake time, it is difficult to record the time and constrain the average recurrence rates. However, turbidite deposits may potentially provide valuable complementary records and reliable constrain on the recurrence intervals and frequency of large earthquakes. And this method has been widely applied along the tectonic activity plate margin such as the Chile(Bernhardt et al., 2015), Japan (Nakajima and Kanai, 2000), New Zealand (Pouderoux et al., 2012), the Cascadia margin of North America (Goldfinger et al., 2003), Alaska (Williams et al., 2019). The southern Okinawa Trough (SOT) near Taiwan is one of the most seismically active areas in the world and features well-developed turbidite deposits. To better evaluate the coupling between the turbidite deposits and the paleo-seismological activity in this area, we investigate a high temporal resolution sediment core HOBAB4-S2, retrieved from the SOT off eastern Taiwan. Based on core photographs, core descriptions, grain size analysis, elemental ratios, and coarse-grained composition analysis, a total of 15 turbidite events (T1-T15) between 1445 AD and 2003 AD were identified in this core (Fig.1), including 3 types of turbidite facies (TI-TIII): thin clay-medium silt turbidites (TI), thick coarse silt turbidites (TII) and fine sand turbidites (TIII). Most of these turbidite events can be correlated with contemporary turbidite events recorded in previously reported sediment cores and/or can be directly related to instrumental and historical earthquake records, indicating that earthquakes are likely the dominant triggering mechanisms for these turbidite events. However, our new sediment core shows an increase in the thickness and occurrence frequency of turbidites during the Little Ice Age (LIA) compared to post-1950 AD. We suggest that the formation of turbidity currents was favored by an enhanced sediment supply due to frequent typhoon-induced heavy rainfalls during the LIA, leading to elevated sensitivity of the source region to earthquakes. This study supports the conclusion that turbidite records from seismically active areas can be used to reconstruct the history of local paleo-earthquakes with the caveat that such studies should be placed in a well-considered climatic context.

Identification and Sedimentary Model of Shallow-water Deltas: A Case Study of the Funing Formation, Subei Basin, Eastern China.

Ziyi Yang[1]*, China University of Petroleum(Beijing) (847297220@qq.com)
Lianbo Zeng[2], China University of Petroleum (Beijing)
Guiyu Dong[3], North China University of Science and Technology

Abstract

The Shallow water deltas are not only a hot spot for sedimentological research, but also a key target for oil and gas exploration. In this paper, Taking the third member (E1f3) of the Funing Formation in the Upper Jurassic as the example, based on the observation of core samples, well logging, cathode luminescence characteristics, and analytical assay, the development conditions, sedimentary characteristics, and sedimentary models of shallow water delta were summarized. These shallow water deltas were deposited in the condition with a gentle terrain platform, the subtropical climate with ample rainfall, abundant supply of source, strong hydrodynamic force, shallow water-body and frequently eustatic lake level. The shallow-water delta is characterized by sediment deposition from traction currents, numerous underwater distributary channel scour structures, overlap scouring structures, sand body distribution with planar features, underwater distributary channels as skeletal sand bodies, and undeveloped mouth bar. Based on these, it is believed that during the deposition period of E1f3, the Gaoyou sag in the Subei Basin has favorable geological conditions for the development of shallow-water delta deposition. The shallow-water delta deposition during the sedimentary periods of the five major sand units in the Funing Formation is all characterized by the front sub-facies, with underwater distributary channels as the framework for sand bodies and multiple intermittent positive rhythm overlapping vertically with the Jianhu Uplift as the source of material supply. Finally, the depositional model for shallow-water delta deposition, during the E1f3 deposition period in the Gaoyou sag has been established, expanding the scope of oil reservoir exploration in the north slope region of the Gaoyou sag and providing important geological evidence for the selection of favorable subtle zones.

Stratigraphy and depositional history of the late Quaternary deposits in the inner shelf of the Korea Strait, SE Korea

Dong-Geun YOO[1]*, Korea Institute of Geoscience and Mineral Resources (dgyoo@kigam.re.kr)
Seok-Hwi HONG[2], Korea Institute of Geoscience and Mineral Resources
Gwang-Soo LEE[3], Korea Institute of Geoscience and Mineral Resources
Gil-Young KIM[4], Korea Institute of Geoscience and Mineral Resources
Seong-Pil KIM[5], Korea Institute of Geoscience and Mineral Resources

Abstract

The inner shelf sequence in this area consists of four sedimentary units, which comprise a set of lowstand, transgressive, and highstand systems tracts formed since the last glacial maximum: incised-channel fill (SU1), estuary (SU2), sand veneer (SU3), and subaqueous delta (SU4). The lowermost unit (SU1), which overlies the sequence boundary, is interpreted as fluvial deposits formed during the last glacial period and belongs to the lowstand systems tract. The lower middle unit (SU2) lying below the ravinement surface represents a paralic component that consists of estuarine sandy mud or muddy sand developed between approximately 13 and 8 cal kyr BP, whereas the upper middle unit (SU3) above the ravinement surface corresponds to a marine component that consists of sand veneer produced by the inner shelf erosion during the ensuing sea-level rise (ca. 8 - 6 cal kyr BP). These two units (SU2 and SU3) belong to the transgressive deposits. The uppermost unit (SU4) regarded as the highstand systems tract formed the Nakdong subaqueous delta including the proximal and distal systems developed after the highstand sea level at approximately 6 cal kyr BP. The lateral transition from the proximal to distal facies suggests a prograding delta system in the Nakdong River, Korea.

Sandstone Petrography and Whole Rock Geochemistry of the Ashio Terrane, a Jurassic Accretionary Complex in Japan: Implications for Provenance and Tectonic Setting

Kyeongtae KIM[1]*, Pukyong National University (rlarudxo0526@naver.com)
Yong Il Lee[2], Seoul National University
Young Ji Joo[3], Pukyong National University

Abstract

As a result of paleo-Pacific plate subduction, which has continued since the late Paleozoic on the East Asia continental margin, a number of accretionary complexes containing Paleozoic and Mesozoic sediments were formed, which and now make up a large part of the Japanese islands. Since these accretionary complexes would have received sediments from the adjacent continent at the time of deposition, the tectonic history and paleogeographic configuration of the East Asian continental margin can be reconstructed by interpreting their provenance. The Ashio terrane, distributed in central Japan, consists of the Upper Paleozoic-Jurassic sedimentary complex and is considered equivalent to the Mino-Tamba terrane in Southwest Japan. This study explores the sandstone petrography and whole-rock geochemistry of sandstone and shale of the Ashio terrane to interpret their provenance and tectonic setting. The Ashio terrane is subdivided into the Kurohone-Kiryu, Omama, and Kuzu complexes, and sandstone and shale samples for this study were collected from the coherent units and a mélange unit of the Kuzu complex. The studied Ashio terrane sandstones are sub-angular to sub-rounded and poorly sorted. The major framework grains are quartz, plagioclase, K-feldspar, and lithic fragments (metamorphic, plutonic, and sedimentary, including radiolarian chert), with minor mica and heavy minerals. The sandstones of the coherent units are classified as lithic arkose, while the mélange sandstones are classified as feldspathic litharenite. In the Qt-F-L diagram of provenance tectonic setting, they are all interpreted to be derived from the recycled orogen provenance. Based on the presence of radiolarian chert grains in the sandstone samples, we hypothesize that at least part of the pre-Jurassic accretionary complexes were probably uplifted and exposed in the hinterland during deposition of the Ashio terrane sediment. Compared to the Post-Archean Australian Shale (PAAS), the Ashio terrane sandstones are enriched in SiO2 and Na2O, while the mélange samples are significantly enriched in MnO, unlike the samples from the coherent units. The shale samples are slightly depleted in major elements compared to the PAAS, except for SiO2, Na2O and K2O. In A-CN-K compositional space, the Ashio terrane sediments from the coherent and mélange units display two slightly different weathering trends, the former from granodioritic composition and the latter from tonalite. They both deviate from the ideal weathering trend from the inferred source, indicating possible effects of diagenetic K-enrichment (i.e. K-metasomatism). The scatter of the samples along the weathering trend suggests that they are products of non-steady-state weathering conditions in the source area. In the tectonic discrimination plots proposed by previous studies, the Ashio terrane sediments fall within the felsic igneous and quartzose sedimentary

provenance fields; only the mélange unit samples are plotted in the quartzose sedimentary provenance field. We will parse the processes that could account for the observed differences in the sediments of the coherent units and mélange unit, such as possible difference in their provenance and/or post-depositional alteration processes, as well as the tectonic history of the East Asia continental margin.

Young Ji Joo[6], Pukyong National University

Abstract

During the Cretaceous period, several non-marine sedimentary basins were formed on the Korean Peninsula around volcanic arcs developed as a result of the subduction of the Paleo-Pacific (Izanagi) Plate beneath the East Asian continent. The Gyeongsang Basin, the largest non-marine Cretaceous basin, is situated in the southeastern part of the Korean Peninsula. Although numerous studies of the sediments (Gyeongsang Supergroup) of the Gyeongsang Basin have revealed the tectonic history of East Asia, most of them have been conducted in the western part of the basin, while the strata in the eastern part have been less extensively studied. The Cretaceous Icheonri Formation is distributed in Gijang-gun, Busan, the eastern margin of the Gyeongsang Basin. This study investigates the provenance and tectonic setting of the Icheonri Formation based on sandstone petrography, detrital mineral chemistry, and whole-rock geochemistry. We also aim to compare them with sandstones from the Sindong and Hayang Groups of the Gyeongsang Supergroup for possible stratigraphic correlation. The analyzed sandstone samples of the Icheonri Formation are very fine- to coarse-grained, subangular to angular, and moderately to poorly sorted. The major framework grains are quartz, plagioclase, and rock fragments. Other minor grains include chromian spinel, epidote, wollastonite, and heavy minerals such as ilmenite. Based on the point-counting results, the sandstones are classified as feldspathic litharenite to litharenite. They are interpreted to have been derived from the transitional arc to undissected arc provenance in the Qt-F-L compositional space of provenance tectonic discrimination. These petrographic characteristics are similar to the sandstones of the Hayang Group, which are dominated by lithic or feldspathic sandstones. The composition of the detrital plagioclase is predominantly albite, suggesting their felsic igneous and/or felsic metamorphic origin, although the effect of albitization is possible. In addition the presence of detrital chromian spinels suggests the existence of ultramafic bodies exposed in the provenance. The chromian spinels were also reported from the Sindong Group sandstones, and they were interpreted to have been supplied from fore-arc mantle peridotite bodies exposed to the west of the Gyeongsang Basin during the Cretaceous. Since their chemistry is similar to that of chromian spinels from the Icheonri Formation, it is possible that the chromian spinels of two strata were supplied from the same source area. This suggests that part of the drainage system that supplied sediments to the western Gyeongsang Basin likely extended to the eastern part of the basin during deposition of the Icheonri Formation. In the tectonic discrimination plots, the bulk geochemical composition of the Icheonri sandstone indicates

deposition in an active continental margin setting, which is consistent with the result of petrographic analysis. Elements reflecting the presence of mafic rocks in the provenance (Sc, V, Cr, and Ni) show a range similar to UCC, while Cr and Ni concentrations are slightly enriched compared to those of active margin sediments. The result of this study is expected to advance our understanding of the tectonic developments in the Gyeongsang Basin and the eastern Asian continental margin during the Cretaceous period.

Hyoun Soo Lim[5], Pusan National University, Geological Sciences, Busan, Korea

Abstract

The Cretaceous Gyeongsang Basin is a basin formed in an active continental margin caused by the subduction of proto-Pacific plates beneath the East Asian continent. The Gyeongsang Supergroup, which fills the Gyeongsang Basin, comprises the lowermost Sindong Group (with few volcanic materials), Hayang Group (containing some volcanic materials), Yucheon Group (dominantly composed of volcanic materials), and the Bulguksa intrusive rocks. Unlike the Sindong and Hayang groups, which consist mainly of detrital sediments, the Yucheon Group shows an intercalated pattern with volcanic materials, posing challenges in correlating or determining its provenance, especially given its isolated nature within the Gyeongsang Basin. The Cretaceous Icheonri Formation, belonging to the Yucheon Group, is located in southeastern part of Korea. So far, no systematic dating has been conducted for this formation. The recent discovery of radiolarian-bearing chert pebbles believed to have been originated from southwestern Japan has raised interest in the provenance of this formation. In this study, LA-MC-ICPMS U-Pb dating was conducted to constrain the depositional age, and to interpret its provenance. The analysis of two samples from the lower part shows a wide age distribution from the Cambrian to the Cretaceous, with a significant proportion in the Cretaceous (44%), Permian (33%), and Proterozoic (11%). The weighted mean 206Pb/238U ages for the youngest age clusters were calculated to be 99.76±0.58 Ma (n=10, MSWD=1.5, 2σ) and 99.86±0.38 Ma (n=25, MSWD=1.5, 2σ), corresponding to the Late Cretaceous Cenomanian stage. In this age spectrum, the notable feature is the significant proportion of mid-Permian zircons, differing from other samples of the Gyeongsang Group. Previous research suggests these mid-Permian zircons may have been transported from Japan. Moreover, radiolarian-bearing chert pebbles were discovered in the upper part of the Icheonri Formation, inland compared to previously reported locations. These findings suggest southwestern Japan as a potential source area. This study provides insights into the paleogeographic relationship between the Korean Peninsula and Japan during the Late Cretaceous, preceding the opening of the East Sea. However, further studies, including paleocurrents analysis of the Icheonri Formation, are necessary for a more precise interpretation of the provenance.

Facies Dependency obvious - Carbon Isotopy fails to be a stratigraphic tool within Lower Toarcian (OAE)

Hans-Joachim ROEHL[1]*, act4carbon (jochenroe@googlemail.com)

Abstract

This talk will focus on the nessessity of interdisciplinary investigations in geological work rather than just on geochemical measurements in the laboratory. Since decades geochemists stubbornly follow the theory that datasets resultig from carbon isotopy analysis proves a global atmospheric signal within the Lower Toarcian (LT) and therefore that Carbon Isotopic analysis can be used as a stratigraphic tool. The so-called Toarcian Carbon Isotope Excursion (T-CIE) also derives from this assumption. In addition such announcements led to the presumption that the trigger for black shale deposition in some marine basins during LT occurred due to climatic changes. But according to literature studies, and there exists a really high amount of publications from many LT locations worldwide, I will point out that a strong facies dependency between changes in Carbon Isotopy and changing lithology exists.

The most important argument for an atmospheric signal is based on especially one author's publications about extracted δ13Corg analysis from "wood"-fragments that show very low δ13Corg values. It remains doubtful and is hard to believe that a more than 185 million years burried "wood" is still carrying the original atmospheric signal. Especially when Coal petrology analysis and other important pre-analyses on this terrestrial derived material is missing.

At some LT locations δ13C values oscillate like an electrocardiogram and do not show a clear T-CIE. Such weak verifyability economists won't use for reliable decisions.

If there had existed a strong atmospheric anomaly on a global scale it should be present in all sections very distinct. The oposite is the case. In regionally independent LT-sections, the datasets do not show a correlation to locations where a clear signal is visible. If it represented a global signal it would be expressed at every location in a similar way.

Without any hint from biostratigraphy, that unfortunately is not well present at every location, the theory of δ13C-Isotopy as a stratigraphic tool would have never been raised.

The data from Carbon Isotopy in LT is much more likely deriving from local to regional oceanic circumstances than showing a global atmospheric Carbon Isotopic constallation. Maybe the T-CIE clearly visible from some rare sections represents a hint for the situation within the waterbody e.g. an oxigen depletion existing within the photic zone and / or biomass recycling processes.

However, from my point of view it is much more important for earth history investigations to focus on the sedimentary development. Observations and correlations to changes in sedimentology are most reliable and can be used to evaluate Sequence stratigraphy in combination with the poor given biostratigraphy in most LT locations. This leads to point out a global development during LT and not the "frantic" attempt to find a very unprominent δ13C T-CIE at every LT-location.

It is most likely that during LT a sea-level driven development caused all phenomenons observed.

The question remains what have been the driving forces for sea-level drop at Pliensbachian /

Toarcian transition.

Sequence stratigraphy in the middle Ordovician shale successions, mid-east Korea: Stratigraphic variations and preservation potential of organic matter within a sequence stratigraphic framework

Uk Hwan BYUN[1]*, Korea institute of Geoscience and mineral resources (buh@kigam.re.kr)
Kwon Yi Kyun[2], Kongju National University
Lee Hyun Suk[3], Korea institute of Geoscience and mineral resources

Abstract

The Jigunsan Formation, a middle Ordovician shale-dominated transgressive sequence in the Taebaeksan Basin, located on the eastern margin of the North China platform, exhibits a distinct distribution pattern in total organic carbon (TOC) content and geochemical properties. This pattern is closely tied to redox conditions associated with decomposition, bulk sedimentation rate (dilution), and productivity. In an effort to clarify this unique distribution, this study aimed to construct a high-resolution sequence stratigraphic framework for the Jigunsan Formation.

The shale-dominated Jigunsan Formation is characterized by a lower layer of dark gray shale deposited during transgression and an upper layer of greenish-gray siltstone deposited during highstand and falling-stage systems tracts. In this study, we adopted the concept of a back-stepped carbonate platform to distinguish early and late transgressive systems tracts (early and late TST), while changes in stacking patterns from aggradation to progradation helped identify highstand systems tracts and falling-stage systems tracts.

The late TST initiates on a rapidly back-stepping sediment surface, displaying a notable peak in TOC content just above this surface, followed by a gradual upward decrease. This distinct TOC distribution pattern in the late TST extends to the maximum flooding surface (MFS). The perplexing nature of this TOC distribution within the late TST is likely a result of both a gradual reduction in productivity during this phase and a gradual increase in dilution effects near the MFS interval.

The reduced production of organic matter during the late TST results in decreasing TOC content toward the MFS, particularly because productivity was primarily governed by benthic biota, as planktonic organisms were not widespread in the Ordovician. The findings of this study will contribute to an improved understanding of source rock distribution in mixed carbonate–siliciclastic successions within a stratigraphic framework, especially relevant for unconventional shale reservoirs.

Shale lithofacies classification criteria: discussion and application

Xinyu JIANG[1]*, China University of Petroleum (East China) (15764250476@163.com)
Nengwu Zhou[2], Sanya Offshore Oil & Gas Research Institute, Northeast Petroleum University
Shuangfang Lu[3], Sanya Offshore Oil & Gas Research Institute, Northeast Petroleum University

Abstract

The term lithofacies refers to the rock or rock assemblage formed in a certain sedimentary environment. Lithofacies classification is the foundation for shale oil and gas evaluation, and numerous papers have reported various shale lithofacies classification methods. Notably, existing methods ignore the significance of organic matter as rock composition, resulting in inaccurate classification results in shale with high organic matter content. Organic matter not only be served as a hydrocarbon generation indicator, but also constitutes shale along with inorganic minerals. Lithofacies classified only by inorganic minerals could not accurately reflect components characteristics of organic-rich shale, which has been discussed by Camp et al.,2016 and Milliken,2014. In this paper, the quaternary diagram lithofacies classification method is proposed, and the volume proportions of the organic matter, siliceous minerals, calcareous minerals, and clay minerals in shale are calculated and served as the four end members. According to the classification boundaries of 25% and 50% volume proportions, all shale lithofacies are theoretically classified into 5 categories and 56 types. This method is applied and compared with the classical ternary diagram in seven sets of typical shale formations in China and the USA. The results show that the lithofacies classified by these two methods are similar with low organic matter content while they vary with high organic matter content in shale. For shales with high organic matter content, the lithofacies types identified by ternary diagram differ greatly from the microscopic observation results, while the lithofacies types identified by quaternary diagram match well with the microscopic observation results, indicating that the quaternary diagram method is suitable for shales with different organic matter content. This work standardizes the shale lithofacies classification process, increased the geological understanding of shale lithofacies, and ultimately provides important insights for the potential guiding significance of quaternary diagram method in shale oil and gas exploration.

Coupling C-N-S-P-Fe systems to reveal bottom euxinia in ancient lakes: Implications on lake-water ventilation and paleowind orientation

Xubin WANG[1]*, Peking University (xubinwang@pku.edu.cn)
Lin Dong[2], Peking University

Abstract

Water circulation is the key to regulating spatial heterogeneity in modern oceans, impacting crucial factors such as nutrients, salinity, and dissolved oxygen concentration. Among them, the dissolved oxygen concentration is closely linked to the ventilation of water mass. While the ancient marine settings have attracted much attention, whether the water ventilation existed in ancient lacustrine environments, as well as how it influenced biogeochemical processes in the lakes, remains a largely unexplored domain. In modern lakes, water circulation is predominantly driven by wind stress, which directly affects oxygen content in the water column. Therefore, the identification of spatial heterogeneity of paleoredox conditions, represented by unevenly distributed euxinia at the bottom water, holds great potential in indicating lake-water ventilation and paleowind orientation. Here, we conducted a systematic investigation of the Triassic Ordos Basin during the Carnian Pluvial Episode, to reveal the paleoredox heterogeneity by analyzing the coupled C-N-S-P-Fe systems. Temporally, the boundary of bottom euxinia contracted from the lake center to the southwestern sections, aligning with the drop of the lake level and the decrease of organic matter loading. Spatially, the southwestern sections exhibit a more anoxic condition than the northeastern sections, which is commonly observed both at large scales (entire lake composed of multiple depocenters) and small scales (part of the lake that belongs to one depocenter). Additionally, the reconstructed distribution of euxinia cannot be solely attributed to changes in water depth and organic matter loading. By comparison to modern oxygen minimum zones, the heterogeneous euxinia of bottom water is probably driven by lake-water ventilation, suggesting a prevailing northeastward paleowind direction. These deductions are supported by the distribution of turbiditic depositions (development of local euxinia) and tuffaceous layers (an indicator of paleowind) during this period. Thus, the reconstruction of paleoredox conditions in ancient lacustrine basins provides a unique opportunity to analyze paleowind, as lake-water ventilation is more sensitive to wind than the oceanic systems.

Abstract

Nutrient supply, particularly phosphorous, has been invoked to be the prerequisite for the early Cambrian radiation of animals. Phosphorus-based hypotheses suggest an adequate supply of reactive phosphorus during this period, supported by the extensive sedimentary record of phosphorites and bedded cherts successions across multiple plates. Furthermore, the elevated concentration of dissolved silica in the oceans further impedes the use of ferric oxyhydroxide particles as shuttles for transporting phosphorus into sediments, because silica could effectively compete with phosphate. However, this hypothesis currently lacks concrete evidence, as the intricate patterns of phosphorus cycling in the Early Cambrian oceans remain unclear.

To address this issue, a comprehensive reconstruction of reactive phosphorus cycling processes in the Early Cambrian oceans is essential. In this study, we utilized SEDEX and P K-edge XANES to assess the partitioning of phosphorus phases and their concentrations in the earliest Cambrian sediments from the Tarim Basin, Northwest China. Our results show that excessive deposition of phosphorus-bearing minerals effectively removes reactive phosphorus from water, leading to oligotrophic environments with a lower C/P ratio in the earliest Cambrian ocean. Subsequent redox-controlled carbon-oxygen-phosphorus biogeochemical feedback mechanisms dominate marine phosphorus cycling, leading to enhanced phosphorus recycling back to the surface water column. Concurrently, nitrogen fixation intensified gradually, signifying a more efficient utilization of nitrate by organisms. The transformation of the phosphorus cycle resolved the prior nutrient crisis and promoted the oxidation of marine photic zones in the earliest Cambrian. Our findings suggest that a phosphorus-starved condition temporarily impeded the pace of Cambrian animal radiation, and overcoming this crisis facilitated a deferred explosion in animal diversity.

Composition, concentrations and strategic resources of metals in Russian black shales (Volga and Baltic sedimentary basins)

TIMUR ALEKSANDROVICH DIU[1]*, Southern Federal University, Rostov-on-Don, 344006, Russia (dyu.timur94@gmail.com)
VLADIMIR I. VYALOV[2], A.P. Karpinsky Russian Geological Research Institute, Saint-Petersburg, Russia
ALEKSEI V. NASTAVKIN[3], Southern Federal University, Rostov-on-Don, Russia
EVGENY P. SHISHOV[4], A.P. Karpinsky Russian Geological Research Institute, Saint-Petersburg, Russia

Abstract

The new results of a study on the concentrations of strategic metals (Re, U, REE, and other) in black shales from the Volga basin (flammable or oil shale), and Baltic sedimentary basins (dictionema shale) are presented.

Shale analysis was carried out using inductively coupled plasma mass spectrometry.

In the Volga basin, 25 shale samples from boreholes and rock outcrops were studied.

In Baltic basins has been analysed more than 750 geological samples which have been selected from 96 boreholes on the area 593 sq. km.

The association of metals with Re in oil shales from Volga basin was identified – max concentrations, ppm: Mo -143, U - 19, Sc – 11, Co - 46, Ni - 281, Cu - 97, Zn- 252, Cr – 109, V – 137, Ti – 0,4 %, and others. The organic matter of oil shales acts as a concentrator of Re and Mo and U. The preferred petrographic type of oil shales for the concentration of Re (max 0,17 ppm), Mo, U, Co, Ni, Cu, Zn, Se, Ag, Sb in them is the colloalginite–vitrinite–clay type of shales.

The metal resources in the explored reserves (2000 million tons) of oil shale of only one Kashpirskoye deposit in the Volga basin are, tons: Re - 192, U - 20600, Sc - 13400, Mo - 151600, V - 172800, Cu - 164000, Zn – 328000, Ti – 8000000.

Valuable metals (Re, U, Mo, Sc and many others) are enriched in the dycthionema shales of the Baltic basin with an increased (up to 15-20%) content of organic matter.

The predicted resources of strategic and other valuable metals in the productive layer of Dictyonema shale in the studied area of the Baltic sedimentary basin (layer thickness 1.8 m, specific gravity of shale 2.4 g/cm3, shale resources 2570 million tons), are (tons): Re (average concentration 0.14 ppm – also and further) – 427, U (219) – 630817, PGE (0.034) – 103, REE (264) – 776990 tons in terms of oxides (TR2O3), Sc (9) – 26450, Mo (223) – 649600, V (950) – 2772550, Cu (102) – 297120, Zn (1340) – 3724280, Ti (3518) – 10413630.

Source of Re and other metals in shales of Volga and Baltic basins was material from the source area and ash material (volcanic activity in nearby regions).

Oil shales of the Volga basin can be considered as a potential raw material source of acutely deficient rhenium, since its content in shales corresponds to (or even higher than) traditional types of rhenium-containing ores (tungsten-molybdenum – Re - 0.03 ppm), molybdenum (0.02 ppm), porphyry copper - 0.11 ppm) of ore deposits of Russia.

Dictionema shales of the Baltic sedimentary basin are believed to be a new nonconventional type of complex ore for Re and U, platinoids, rare-earth and other valuable metals.

Abstract

Diagenesis plays an important role in porosity evolution of shale reservoir. The study of petrography from macro to micro-nano scale on organic-rich shale in the first member of Qingshankou Formation, Central Depression, Songliao Basin, was investigated by using core observation, thin section identification, scanning electron microscopy observation, cathodoluminescence analysis and TIMA analysis. Based on the above research, a series of analytical tests were conducted, including electron probe microanalysis, micro-drilling sampling for carbon and oxygen isotopes, rare earth elements analysis, nitrogen adsorption experiments and high-pressure mercury intrusion experiments to reveal the differences in diagenesis among organic-rich shales, as well as the impact of diagenetic on the evolution of porosity. They indicate that the study area can be divided into organic-rich quartz-feldspathic shale (OQF-shale) and organic-rich dolomitic shale (OD-shale). Due to the distinct differences in mineral composition, the diagenesis and pore evolution of these two types of shale differ significantly, as detailed below. OD-shale has undergone several diagenetic-porosity evolution processes, manifesting successively as porosity reduction by compacting, porosity increase by clay mineral dissolving, porosity reduction by ankerite cementing, porosity increase by ankerite and clay mineral dissolving, porosity reduction by clay mineral cementing and porosity increase by organic matter cracking. The pore types of OD-shale are dominated by micron-inorganic pores such as dolomite intergranular pores, ankerite and clay mineral dissolution pores, followed by nano-organic pores and tectonic fractures. The current effective porosity of them ranges from 3.4% to 12.5%, with an average of 8.6%. OQF-shale has undergone several distinct diagenetic-porosity evolution processes, which are specifically manifested as porosity reduction by compacting, porosity increase by clay mineral and detrital feldspar dissolving, porosity reduction by clay mineral cementing, porosity increase by organic matter cracking and clay mineral dissolving. OQF-shale are primarily dominated by nano- organic pores and organic hydrocarbon generation fractures, followed by inorganic pores such as micro-clay mineral dissolution pores, nano-clay mineral intercrystalline pores, and nano-pyrite intercrystalline pores. The current effective porosity of

them ranges from 2.1% to 14.6%, with an average of 6.4%. Thus, the OD-shale may serve as indicators of potential source rocks for hydrocarbon accumulation in the study area.

Uranium and rare-earth elements in dictyonema shale of the Baltic sedimentary basin

TIMUR ALEKSANDROVICH DIU[1]*, Southern Federal University, Rostov-on-Don, 344006, Russia (dyu.timur94@gmail.com)

Abstract

The results of long-term research into dictionema shales from the Baltic basin (in the Leningrad region and the Kaibolovo-Gostilitsky area in Russia) for uranium and rare earth elements, as a promising, unconventional source for scarce strategic raw materials, are presented. New data on the material and petrographic composition of the shales and their metalliferous content are presented, as well as information on the specific features of uranium mineralization in the shales. The distribution of uranium within the shale formations, both in terms of area and well profiles, is detailed. For the first time, data on the concentration of rare earth elements (REE) in dictionema shale samples from a large analytical sample size (672) is presented. The distribution patterns of REE within the research area are also illustrated for the first time.This information can be used to develop strategies for extracting and managing these elements from a promising source of raw materials. The distribution of REE (rare earth elements) over the search area has been noted, as well as in the sedimentary strata of the wells. An additional study of the mineral impurities in the shale has been conducted using a new technique of area scanning with an electron probe microanalyser, using the Feature software module. Correlations between the concentration of uranium and other elements have been clarified. The bonds between uranium and REEs with organic carbon have been described. Various forms of uranium and REEs in the shales have also been described, as well as the role of organic matter in their concentrations. In addition, the conditions for the formation of mineralization of uranium and REEs in black shale have been detailed.The uranium content in the shales within certain areas of the Kaibolovo-Gostilitskaya region was estimated, and the potential cost of possible recoverable industrial reserves of potential uranium ore raw materials from the studied regions was clarified. It was also determined that the mineral resources of uranium and rare earth elements in Russia and around the world could be significantly increased through their presence in these black shales.

Differential enrichment of organic matter in saline lacustrine black shales: an example from the Chezhen Sag in Bohai Way Basin, China

ZHI CHAI[1]*, School of Geoscience, China University of Petroleum (chaizhi5137@163.com)
ZHONGHONG CHEN[2], School of Geoscience, China University of Petroleum
Moïse Luemba[3], School of Geoscience, China University of Petroleum

Abstract

Organic matter-rich black shale in the salt lacustrine basin is of great significance as a source rock for conventional oil and gas exploration, and has become a prominent target for unconventional oil and gas exploration and development in recent years. However, the mechanism of differential organic matter enrichment in saline lacustrine black shales is still controversial and needs to be further clarified. In this study, taking the Chezhen Sag in Bohai Bay Basin as an example, total organic carbon, rock pyrolysis, molecular markers, and inorganic elements analyses were performed on the black shales from the fourth member of the Palaeogene Shahejie Formation. The abundance and type of organic matter, paleoclimate, paleowater depth, paleoproductivity, paleo-salinity, and paleo-redox conditions were investigated. The results show that the eastern part of the Chezhen Sag has higher organic matter abundance and is dominated by type II1 and type I. On the contrary, the western part of the Chezhen Sag has lower organic matter and is dominated by type III and type II2. The differential enrichment of organic matter between the eastern and western regions is related to the different evolution of the lake. The highly evaporative environment led to reducing paleowater in the eastern region, and the greater water depth led to reducing paleowater in the western region. Compared with the western region, the eastern region has high salinity and paleoreductivity. Hereby, the paleosalinity and paleoreductivity are the main factors for the organic matter enrichment of the black shales. This is due to the fact that higher salinity favors activities such as halophilic bacteria, which leads to higher paleoproductivity. Redox conditions had little effect on organic matter enrichment, which is related to the fact that black shales as a whole developed under anoxic-redox conditions. In conclusion, high paleoproductivity and paleosalinity conditions paly a key role in the enrichment of organic matter in lacustrine black shales.

Abstract

Carbon dioxide is an essential component of atmosphere that determines climatic and environmental conditions of Earth. However, atmospheric CO2 levels (pCO2) during the explosive diversification of animals during the Ediacaran–Cambrian transition is poorly constrained. Here we explored using carbon isotope signatures of carbonaceous algal fossils from seven black shale fossil deposits (~553 to ~508 Ma) to track pCO2 variations during this critical geological period. Our results reveal an increase of pCO2 from ~5 to ~16 PAL during ~553–529 Ma, followed by a progressive decrease to ~9 PAL and ~5 PAL at ~517 Ma and ~508 Ma, respectively. Temporal pCO2 changes interpreted here are consistent with contemporaneous marine strontium isotope variations, providing robust evidence for validity of the results and tectonic control on pCO2. Box modelling results further confirm that the pCO2 variation can be well explained by changes in the rate of deep-source CO2 input through outgassing. The pCO2 variations suggest a three-stage greenhouse–hothouse–greenhouse trajectory of planetary climate during the Cambrian explosion, which could have significantly impacted marine environments and accordingly animal diversification. Taken together, our results suggest a close interplay of tectonic, climatic, and biotic processes during the Cambrian explosion, and emphasizes the importance of black shale as a unique archive for the paleoenvironmental history of Earth.

ORGANIC GEOCHEMICAL CHARACTERIZATION OF THE LOWER GONDWANA CARBONACEOUS SHALES OF THE EAST SIANG DISTRICT IN THE ARUNACHAL HIMALAYA, INDIA

DIPJYOTI BORSAIKIA[1]*, DEPARTMENT OF GEOLOGICAL SCIENCES, GAUHATI UNIVERSITY, INDIA (dipjyoti.borsaikia@gmail.com)
SARAT PHUKAN[2], DEPARTMENT OF GEOLOGICAL SCIENCES, GAUHATI UNIVERSITY, INDIA

Abstract

The study area forms a part of the Eastern Himalayas which characterize the Lower Gondwana Group of rocks. The present study aims to conduct hydrocarbon source rock geochemistry of the outcrop samples of carbonaceous shales, exposed along the Pasighat-Aalo road section of East Siang District, Arunachal Pradesh, India belonging to the Bhareli Formation of the Lower Gondwana Group. The organic geochemical studies of the carbonaceous shale of this Formation area have been investigated using Proximate analysis, Ultimate analysis (CHNSO), Total Organic Carbon (TOC), and Rock-Eval Pyrolysis techniques. The analytical results have been used to assess the richness of organic matter and its hydrocarbon potentiality, types as well as thermal maturity of organic matter. Proximate analysis of the carbonaceous shale samples shows low moisture content (0.49 to 1.8 wt%), low volatile matter (4.69 to 9.84 wt%), and very high ash content (81.94 to 94.06 wt%) in air-dried basis. The sulfur content obtained from ultimate analysis is almost negligible except for a few samples which range from 1.64 to 2.56 %. The Total Organic Carbon (TOC) values of the carbonaceous shales, ranged from 3.27 to 11.52 % with a mean of 6.70 % indicating promising potential source rock with very good to excellent organic richness. However other parameters like S1 and S2 values that are derived from Rock-Eval Pyrolysis have a very low range of values with a mean of 0.16 (mgHC/gTOC) and 1.60 (mgHC/gTOC) respectively, indicative of poor to fair hydrocarbon source condition for hydrocarbon generation. Values of Hydrogen Index (HI) (mean of 24.24 mg HC/gm TOC) and OI (mean of 9.18 mg HC/gm TOC) that are being plotted in the modified Van Krevelen diagram indicate Type IV kerogen signifies that the organic matter may be formed from various origins which have undergone significant oxidation or might be in a certain situation perhaps detrital organic matter might be oxidized directly by thermal maturation, sedimentological recycling of materials, or organic facies that has been reworked from a previous depositional cycle. Based on the Rock-Eval thermal maturity parameters such as Tmax (pyro), and PI, the plot of PI versus Tmax (pyro) indicates that the organic matter of carbonaceous shale samples falls in the hydrocarbon generation zone which is indigenous. Accordingly, the organic matter of carbonaceous shale samples of the Bhareli Formation as indicated by the HI vs Pyro Tmax (mean of 449 ºC) plot is characterized by a Type IV dry gas category that falls within the mature stage of the Oil window zone.

Sulfate-reducing microfossil Qingjiangonema from the early Cambrian black shale of South China

Xingliang ZHANG[1]*, Northwest University (xzhang69@nwu.edu.cn)

Abstract

Sulfate reduction is an essential metabolism that maintains biogeochemical cycles in marine and terrestrial ecosystems. Sulfate reducers are exclusively prokaryotic, phylogenetically diverse, and may have evolved early in Earth's history. However, their origin is elusive and unequivocal fossils are lacking. Here we report a new microfossil, Qingjiangonema cambria, from ~518-million-year-old black shales that yield the Qingjiang biota. Qingjiangonema is a long filamentous form comprising hundreds of cells filled by equimorphic and equidimensional pyrite microcrystals with a light sulfur isotope composition. Multiple lines of evidence indicate Qingjiangonema was a sulfate-reducing bacterium that exhibits similar patterns of cell organization to filamentous forms within the phylum Desulfobacterota, including the sulfate-reducing Desulfonema and sulfide-oxidizing cable bacteria. Phylogenomic analyses confirm separate, independent origins of multicellularity in Desulfonema and in cable bacteria. Molecular clock analyses infer that the Desulfobacterota, which encompass a majority of sulfate-reducing taxa, diverged ~2.41 billion years ago during the Paleoproterozoic Great Oxygenation Event, while cable bacteria diverged ~0.56 billion years ago during or immediately after the Neoproterozoic Oxygenation Event. Taken together, we interpret Qingjiangonema as a multicellular sulfate-reducing microfossil and propose that cable bacteria evolved from a multicellular filamentous sulfate-reducing ancestor. We infer that the diversification of the Desulfobacterota and the origin of cable bacteria may have been responses to oxygenation events in Earth's history.

Application of in situ Rb-Sr geochronology for dating of black shale

Zhongwu LAN[1]*, Institute of Geology and Geophysics, Chinese Academy of Sciences (lzw1981@126.com)
Kyle Larson[2], University of British Columbia
Darwinaji Subarkah[3], University of Adelaide
Qin Ye[4], China University of Geosciences
Jun Hu[5], China University of Geosciences
Jinnan Tong[6], China University of Geosciences

Abstract

Shale is widespread in the geological record and contains important information about biological evolution, seawater chemical composition, hydrothermal mineralization, and oil and gas migration. As such, quantifying the timing of deposition or hydrothermal alteration of shale is critical to decoding these geological, biological and environmental processes. Geochronology of shale, however, can be challenging, particularly where biostratigraphy is inapplicable. A number of direct and indirect dating methods have been attempted but often can only provide information on maximum and minimum depositional ages. The recent development of in situ Rb-Sr geochronology methods, via tandem inductively coupled plasma–mass spectrometry, now allows the assessment of Rb-Sr age information in K-bearing specimens without losing the associated textural context of each targeted laser spot. Because black shale contains abundant authigenic K-bearing clay minerals, it is possible to date using the Rb-Sr decay system. In situ Rb–Sr geochronology has been successfully applied to date Proterozoic shale in the McArthur Basin of northern Australia to constrain their depositional and post-depositional, fluid-induced metasomatism or hydrothermal alteration events. Herein, we expand the application of this technique to date the Mesoproterozoic, Neoproterozoic, and Phanerozoic black shale in South China and North China cratons. A Rb-Sr isochron age of 1078 ± 78 Ma was obtained from the Mesoproterozoic black shale of Xiamaling Formation from the North China Craton, which is interpreted to represent the timing of fluid-induced metasomatism or hydrothermal alteration. In addition, an Rb-Sr isochron age of 231 ± 12 Ma, obtained from the Mesozoic black shale of Ordos Basin in the North China Craton, is interpreted as depositional age. Finally, both depositional and post-depositional hydrothermal alteration events have been identified from the Marinoan black shale in South China Craton. An Rb-Sr isochron age of 630 ± 27 Ma from Marinoan black shale strata represents the timing of deposition, whereas additional Rb-Sr isochron dates in the same rocks of 554 ± 27 Ma and 545 ± 17 Ma are consistent with the timing of a regional hydrothermal event potentially related to the large-scale Bingdongshan Pb-Zn deposit proximal to the study area.

Shale gas sweet spots comparison between marine shale and transitional shale of China

Qin ZHANG[1]*, PetroChina, Research Institute of Petroleum Exploration and Development (zhangqin2169@petrochina.com.cn)
Zhen Qiu[2], PetroChina, Research Institute of Petroleum Exploration and Development
QUN Zhao[3], PetroChina, Research Institute of Petroleum Exploration and Development
Wen Liu[4], PetroChina, Research Institute of Petroleum Exploration and Development
Weiliang Kong[5], PetroChina, Research Institute of Petroleum Exploration and Development

Abstract

The geological reserves of shale gas in China are 134.42×1012m^3, with marine and transitional shale gas resources accounting for 43.95% and 29.82% respectively. More than 50% of the discovered conventional natural gas reserves in China have derived from transitional shale. In 2022, shale gas production from Longmaxi shale has reached 240×108m^3. Transitional shale gas is mainly distributed in the Carboniferous-Permian strata, and horizontal wells in the eastern margin of the Ordos Basin have yielded high production (1.1-7.9×104m^3/d). However, the degree of exploration in transitional shale is far behind of the marine shale. In order to fully understand the characteristics of transitional sweet spots and avoid blindly applying experiences from marine shale gas, it is crucial to conduct a comparative analysis of the marine and transitional shale.

Core observation, thin section identification, organic geochemistry, reservoir analysis, gas occurrence, and elemental analysis have been carried out. The research shows the two have significant differences in 5 aspects: (1) Differences in continuity. The sweet spot of the Longmaxi Formation is mainly distributed in the middle-lower section of the Long1 11, showing strong lateral continuity and stable distribution; sweet spots in Shanxi Formation are unevenly distributed in both bottom (well DJ51) and the middle section of the Shanxi Formation (well DJ3-4); (2) Differences in organic geochemistry. TOC of the Longmaxi shale is above 4%, with predominantly sapropelic organic matter, Ro generally exceeding 2.5%, and even reaching graphitization; TOC of the Shanxi shale is higher, ranging from 4.19% to 43.9% and the maceral of organic matter is mainly vitrinite, with Ro ranging from 2.0 to 2.61%; (3) Differences in reservoir characteristics. The sweet spot in Longmaxi shale is dominated by quartz (average 77.5%) and the clay minerals are dominated by illite (>80%). The pore types are mainly organic pores, with both mesopores and micropores well developed. In Shanxi shale, the clay content is higher than quartz with average value of 50.2%, and the clay minerals is dominated by kaolite (average 46%). The organic matter mainly develops micropores, and the mesopores and macropores are mainly developed in clay minerals. (4) Differences in gas occurrence. The marine Longmaxi shale is dominated by free gas (57%-87%), exhibiting early high production followed by rapid decline (average decline rate of 65% per well in the first year), whereas the Shanxi Formation is dominated by adsorbed gas (average 64%), showing early low production but stable production afterward (20-30% decline rate in the first year); (5) Differences in the formation mechanisms. The sweet spots in marine shale is mainly controlled by redox conditions and

paleoproductivity, with geological events such as volcanic activity, glacier melting, and biologic extinction playing indirect roles. While in the transitional shale, in addition to paleoproductivity and redox conditions, the unique detrital inputs also play an important role in the formation of sweet spot.
Because of the significant differences, it’s necessary to formulate specific methods and techniques to promote transitional shale gas exploration.

The black shale distribution pattern on the Middle Yangtze Region, South China during Ordovician-Silurian transitional period

Chuanshang WANG[1]*, Wuhan Center of China Geological Survey (wangchuanshang@163.com)
Kai Wei[2], Wuhan Center of China Geological Survey
Xiaofeng Wang[3], Wuhan Center of China Geological Survey
Jörg Maletz[4], Institute of Geology, Free University of Berlin, Germany

Abstract

To study the distribution pattern of the black shale during Ordovician-Silurian transitional period is essential for the optimization of the target zone for shale gas exploration and commercial exploitation in South China. The black shale was deposited in the foreland basin and the intracratonic basin during the Guangxi Movement period when the Yangtze Block subducted southward to the Cathaysia Block. However, the black shale shows strong heterogeneous from place to place. Four typical sections for different facies from south to north, i.e., the Kapeng section, Jinglongqiao section, Hamadong section and Longtoupo section, were measured to decipher the tempo-spatial distribution pattern of the black shale.

The south most section is the Kapeng section in Baojing County, western Hunan Province. The black shale is rather thin and much more silty at the lower part of the section, comparing with other sections on the middle Yangtze region. The age of the black shale is from Katian of Late Ordovician to Rhuddanian of early Llandovery (Silurian) according to the graptolite zonations. The most spectacular deposit of this section is the turbidite sandstone of ca. 100 m in thickness, which shows the cycles of coarsening upward successions from siltstone or silty shale to sandstone.

The sequence was dominated by chert beds in the Jinglongqiao section of Cili County, western Hunan. The Hirnantian bed and probably the earliest Silurian strata are missing in this area since the common graptolite fossils *Rectograptus* and the typical Silurian graptolite fossil *Avitograptus* were found below and above the O/S boundary, respectively. Similar to the Jinglongqiao section, the graptolite fossils of *Tangyagraptus* and *Paraorthograptus* were found just below the O/S boundary at Hamadong section in Yongshun County, western Hunan. The evidence shows that the Cili-Yongshun area was once occupied by the underwater uplift or the peripheral bulge during the Ordovician-Silurian transitional period, and the bulge was then migrated northward and the area was subsided as the foreland basin during the earliest Silurian.

The north most section is the Longtoupo section in Zigui County, western Hubei Province. The section is the typical section for the intracratonic basin, where the black shale sequence from Rhudanian to mid-Aeronian were revealed by the abundant graptolite fossils.

To sum up, the tempo-spatial distribution of the black shale, as the response to the migration of the foreland basin, can be depicted more precisely by the constrain of graptolite zonations. The diachronous boundaries of the black shale and the time interval of the gaps within the black shale can be a good proxy to illustrate the migration of the intracratonic basin, the peripheral bulge and

the foreland basin from south to north.

Sedimentary features and their hydrocarbon significance of lacustrine shale under different hydrodynamic conditions

Zhenglian PANG[1]*, Research institute of petroleum exploration and development (zhenglian20@126.com)

Abstract

According to the traditional view, shale deposits are usually regarded to be deposited in a relatively slack and deep water environment. However, as the lacustrine shale oil and gas have been developed continuously in recent years, shale is revealed that can deposit under different hydrodynamic conditions. The Upper Triassic Chang 7 Member in the Ordos Basin, which contains thick black shale and well developed gravity flow deposits provides an good opportunity to investigate the sedimentary features of lacustrine shale under different hydrodynamic conditions caused by gravity flows.

We integrate core observation, thin section petrography analysis, X-ray diffraction, major and trace element analysis, total organic carbon testing, electron microscopy, energy spectrum analysis, rock pyrolysis and analysis of group composition of hydrocarbon on shale to carry out the lithofacies classification, palaeoenvironment analysis, depositional models reconstruction, and hydrocarbon significance study.

Based on the development of silty laminas and thickness of the laminaset/bedding, the Chang 7 shale was classified into five lithofacies, including Thick silty laminaset shale (Type Ⅰ), horizontal bedding shale (Type Ⅱ), massive shale (Type Ⅲ), Thick laminaset shale (Type Ⅳ), and Thin laminaset shale (Type V), and 11 subtypes of laminas according to the lamina morphology. By studying the paleo-water depth, paleo-settling rate, paleo-productivity, paleo-redox, and clastic influx of each lithofacies, combined with the abundances of organic matter, palaeoenvironment and depositional processes of each lithofacies were studied, and depositional models of Chang 7 shale influenced heavily by gravity flows were proposed. In these models, the diversity both of hydrodynamic conditions and clastic influx induced by gravity flows, combing the variation of paleo-productivity, led to the heterogeneity of shale.

Based on the relation between TOC and five paleoenvironmental proxies, paleo-productivity has the strongest influence on the accumulation of organic matter. The rock pyrolysis, analysis of group composition of hydrocarbon, and mineral composition of different lithofacies reveal that Type Ⅰand Ⅱ lithofacies contain more light hydrocarbons, and are much easier to be fractured, which are more suitable for the technologies of horizontal well and hydrofracture. By contrast, Type Ⅲ, Ⅳ, V lithofacies are more suitable for the technology of in-situ conversion process.

According to this work, sedimentary features and heterogeneity of lacustrine shale under different hydrodynamic conditions were researched, and their hydrocarbon significance was also analyzed.

Jingqiang Yu[5], Geophysical Research Institute,Shengli oilfield,SINOPEC

Abstract

Jiyang Depression in Bohai Bay Basin is a typical Cenozoic continental rift basin with abundant shale oil resources. The fine-grained sedimentary lithofacies of continental rift basins shale in China change rapidly, with diverse facies and strong heterogeneity,which lead to many uncertain factors in later stage of exploration and development of shale oil.

Based on the complex lithological characteristics of shale in Jiyang Depression, the concept of "lithofacies assemblages" was proposed in shale oil exploration and development in the oilfield. However, due to factors such as insufficient logging and core data, and low seismic data resolution, it is still difficult to accurately describe the distribution pattern of lithofacies aessemblages.

Takes the upper 4th member of Shahejie formation(E2S4S)in Dongying sag of Jiyang Depression as an example,a lithofacies assemblages division scheme that can match the current seismic data resolution was established, and three lithofacies assemblages models were constructed: One interlayer with variable thickness models, variable interlayer quantity with the same thickness models, variable interlayer quantity with variable thickness models. Then the seismic response characteristics of different lithofacies assemblages were clarified through forward modeling of wave equation.Based on this, the seismic waveform clustering method and geostatistical inversion techniques were studied to predict the distribution characteristics of different lithofacies assemblages.

The main lithofacies developed in the upper sub section of E2S4S in Dongying sag are laminated argillaceous limestone and laminated calcareous mudstone, which are interbedded,or form different lithofacies assemblages as interlayers.The seismic response characteristics of different lithofacies assemblages vary greatly,as the number and thickness of interlayers increase, the seismic amplitude of the top interface of layers shows a downward trend,The variation characteristics of the bottom interface are more complex,The seismic amplitude of the layer bottom interface decreases with the increase of the thickness of a single interlayer, and significantly increases with the increase of the number of interlayers,the variation degree of seismic amplitude at the bottom interface of different layers is quite different.A negative polarity reflection is formed by a single interlayer, and the reflection of multiple intelayers produces a composite wave, and the polarity of seismic reflection also changes. As the thickness of the interlayer increases, the seismic reflection amplitude of the interlayer increases.

The seismic waveform clustering method can predict the distribution characteristics of lithofacies on a large scale, especially for areas with limited or no drilling data.The geostatistical inversion method can predict the spatial distribution of different lithofacies on a small scale, and five types of lithofacies have been identified. The vertical and horizontal changes in lithofacies are clear. The prediction results of each layer are in agreement with drilling results to a degree of 90%.

The Carnian Pluvial Episode(late Triassic) in northeastern Tethys: Lacustrine sedimentary records,petroleum geological significance from the Yanchang Formation,Ordos Basin, central China

Xiangbo Li[1]*, Northwest Branch, Research Institute of Petroleum Exploration and Development, PetroChina (yang_zl@petrochina.com.cn)
Huaqing Liu[2], Northwest Branch, Research Institute of Petroleum Exploration and Development, PetroChina

Abstract

The Carnian Pluvial Episode (CPE) is among the most remarkable climate abrupt event registered on earth. The CPE is characterized by abrupt changes in climate with consequences in depositional environments, source rocks, and hydrocarbon accumulation in lake basins. The case study deals with the Triassic Yanchang Formation in the Ordos Basin, a major onshore petroliferous basin in China. The analysis of global palaeoclimatic changes through outcrop and core observation, lab tests, and seismic interpretation, allow to review the sedimentation and hydrocarbon habitats of the Yanchang Formation. After this study, five conclusions have been achieved.

(1) The significance of the CPE in the Yanchang Formation was stablished. At the boundary between Chang 7 and Chang 8, a sudden facies change was found, which was related to the CPE event. Chang 7 black shales are considered the sedimentary response of CPE event.

(2) Three palaeoclimatic conditions were recognized: arid (Ladinian), warm-humid (Carnian), and semiarid-subhumid (Norian-Rhaetian).

(3) During the Carnian Age and CPE, the lake basin experienced a rapid transgression followed by a slow fluctuating regression characterized by periodic lake water concentration, flourishing organisms, high organic productivity, small consumption, and weak diluting effects, which may have facilitated the accumulation of organic rich source rocks.

(4) Ladinian and Norian-Rhaetian Ages were characterized by a relatively arid palaeoclimate, with limited precipitation and seasonal rainstorms developed before and after the CPE. In consequence, flood events dominated the occurrence and distribution of large-scale sands in central basin areas.

(5) Owing to the influence of the CPE and abrupt changes in palaeoclimate before and after the episode, two xenoconformities turned up vertically inside the Yanchang Formation and dominated lithologic-stratigraphic traps and hydrocarbon distribution. This study fills a gap in understanding the sedimentary response of the CPE in the Pangea at the east margin of the Paleo-Tethys.

Lithofacies Characteristics and Sweet Spot Distribution of Lacustrine Shale Oil Reservoirs: A Case Study of the Second Member of the Kongdian Formation in the Cangdong Sag, Bohai Bay Basin

Yuan ZHAN[1]*, China university of petroleum (east china) (zy2k19@163.com)
Chengyan LIN[2], China university of petroleum (east china)

Abstract

In contrast to marine shale oil reservoirs, lacustrine shale exhibits rapid lithofacies changes and strong mineral compositional heterogeneity, posing new challenges for the evaluation and distribution prediction of shale oil sweet spots. The oiliness, reservoir properties, oil fluidity, and fracability of different lithofacies were analyzed using emission-scanning electron microscopy (FE-SEM) observation, low-pressure nitrogen physisorption (LNP) analysis, mercury intrusion porosimetry (MIP), nuclear magnetic resonance (NMR), and triaxial compression testing. Based on the mineral composition obtained from X-ray diffraction (XRD) analysis, total organic carbon (TOC) content, and sedimentary structure, four lithofacies were classified, which are organic-rich laminated calcareous shale (LC), organic-rich laminated siliceous shale (LS), organic-rich laminated mixed shale (LM), and organic-poor massive calcareous shale (MC). Considering the factors of oiliness, reservoir properties, oil fluidity, and fracability, the LC and LS lithofacies were determined as being high-quality sweet spots (type I). Within the stratigraphic sequence divided by GR-INPEFA curves, random forest algorithm of sensitive well logs was used to classify the lithofacies, after which the distribution of sweet spots was predicted. The results reveal that the sweet spots exhibit regular changes in their vertical distribution and a ring-like pattern in their planar distribution, influenced by variations in the sedimentary environment. This finding can offer valuable guidance for the future exploitation of shale oil in the Guandong region.

Analysis of favorable lithofacies for the development of lamellar sparry calcite veins in Paleogene lacustrine black shale of Jiyang Depression, China

YUNJIAO ZHANG[1]*, China University of Petroleum (East China) (1184548291@qq.com)
GUANMIN WANG[2], China University of Petroleum (East China)
ZIYUAN YIN[3], China University of Petroleum (East China)

Abstract

The lamellar sparry calcite vein, a significant outcome of shale diagenesis and organic matter evolution in the Paleogene lacustrine black shale of Jiyang Depression, serves as a crucial indicator for evaluating shale exploitability. However, its heterogeneous distribution poses challenges in predicting its occurrence, limiting shale oil exploration and development. This study focuses on the Upper Es4 - Lower Es3 black shale of the Paleogene, employing various analytical methods such as petrology, petrography, isotope geochemistry, cathodoluminescence, inclusion temperature measurement, and electron probe. The analysis reveals that lamellar sparry calcite veins are predominantly found in organic-rich lamellar calcareous mudstone and argillaceous limestone. Statistical data indicates that lithofacies with lamellar structure, TOC (total organic carbon) > 2%, carbonate content of 10% - 70%, and argillaceous content of > 20% are conducive to vein development. The formation mechanism of lamellar sparry calcite vein determines its differential distribution in shale. These veins is tied to the semi-mature to mature stage of organic matter. Micritic calcite in the lake undergoes dissolution by organic acids, forming vein-forming fluids alongside fluids resulting from clay mineral conversion. Hydrocarbon generation pressure leads to the creation of horizontal micro-fractures along weak bedding planes in lamellar shale, providing channels for fluid migration. The vein-forming fluid converges, recrystallizes in the surrounding pressure relief area, and develops into lamellar sparry calcite veins. The study identifies TOC content as a major factor influencing vein development, with significantly reduced development when TOC is < 2%. Carbonate and clay minerals play pivotal roles in providing the material and fluid basis for calcite vein development, while the lamellar structure enhances shale cracking. Considering the organic matter evolution and burial history in Jiyang Depression, lamellar sparry calcite veins are primarily generated at depths ranging from 2500 m to 3500 m, with diminished formation beyond 3500 m.

In-situ heating-induced pore structure evolution in low-medium-maturity Paleogene lacustrine shale, Bohai Bay Basin, China: Insights from integrated experimental and numerical approaches

Guoshuai Bai[1]*, China University of Geosiciences(Wu Han) (baiguoshuai@cug.edu.cn)
Guohui Chen[2], Nepu Sanya Offshore Oil&Gas Research Institute
Zhongxian Cai[3], China University of Geosiciences(Wu Han)
Shu Jiang[4], China University of Geosiciences(Wu Han)

Abstract

The effective development of shale reservoirs with low to medium maturity necessitates a comprehensive understanding of pore evolution dynamics during in-situ heating. These dynamics are investigated through experimental analysis and numerical simulation using shale samples selected from the lower sub-member of the fourth member of the Paleogene Shahejie Formation in the Damintun Sag, Bohai Bay Basin, China. Seven shale samples, exhibiting a maturity range of 0.54% to 2.5%, were analyzed to assess pore characteristics across varying maturity stages, using low-temperature gas adsorption (LTGA), mercury intrusion capillary pressure (MICP), field emission scanning electron microscopy (FE-SEM), and nuclear magnetic resonance (NMR) techniques. Subsequently, a 3D geological model of in-situ heating in the Damintun Sag was developed using the COMSOL Multiphysics software. This model enabled the simulation of temperature, maturity, and porosity distribution and their evolution during heating. The results revealed that the evolution of organic and inorganic pores in shale was predominantly influenced by hydrocarbon generation, clay mineral transformation, and dissolution. Organic pores consisted mainly of mesopores and macropores, while inorganic pores were predominantly mesopores. An increase in maturity led to a transformation of some organic pores into inorganic ones. It was observed that, from low to high maturity stages, shale porosity and pore volume initially increased significantly—by 209.6% and 616.2%, respectively—followed by a decrease of 8.6% and 19.5%. The contribution of organic porosity to the total porosity could reach as high as 84.9%. Under a constant temperature of 600°C in horizontal heating wells, all organic matter within the shale of the hexagonal well network reached an overmature stage after 2,580 days of heating. Notably, after 2,100 days of heating, the most substantial increase in shale porosity was observed within the bounds and extending an additional 5 m beyond the periphery of the entire hexagonal well network.

Evaluation of organic matter, thermal maturity and hydrocarbon potential of source rocks from southwest of Rwanda

THEOPHILE MUGERWA[1]*, University of Rwanda (luanmugerwa@gmail.com)

Abstract

Researchers have identified areas of hydrocarbon potential in Lake Kivu Graben, especially as a source of power supply. However, organic geochemical prospecting for hydrocarbon and energy content assessment is inadequate for the identified areas. The study aimed at determining the organic petrography of peat deposits in Western Province, Rwanda

Forty (40) subsurface peat samples (1 to 10 m depth) from three locations: Gishoma, Mashya, and Gihitasi were collected, air-dried, and pulverized and screened based on Von Post degree of humification. Fourteen samples were subjected to geochemistry and organic petrographic analysis. The macerals variations are as follows: huminite (57.5 Vol %) > liptinite (28.8 Vol %) > inertinite (13.7 Vol %). The bulk geochemical parameters are TOC (14.0-40.0%), S1 (2.8-19.9 mg HC/g), S2 (27.9-103.7 mg HC/g rock), S3 (12.7 mg HC/g to 33.43mg HC/g), Tmax (406 - 428oC) and production index (PI) (0.09 to 0.16).
.The sediments are excellent source rocks and may generate mixed oil and gas at appropriate maturation. The organic matter is classified as type II and III Kerogen. The Tmax was less than 4300C, and the ratios of Ts/Tm and M/H indicated that the peat deposits are thermally immature.
The peat deposits in Western Province, Rwanda are very rich in organic matter of mainly terrestrial precursor and capable of generating gas and some oil at appropriate maturation

Coupling of nitrogen biogeochemical cycling and phytoplankton community structure before and after the Late Ordovician mass extinction in South China

Ruining HU[1]*, Central South University (huruining611@163.com)
Wenhui Wang[2], Central South University
Jingqiang Tan[3], Central South University

Abstract

The Ordovician–Silurian transition (OST) is a crucial geological interval in Earth history, coinciding with the first of the 'Big Five' Phanerozoic mass extinction events (ca. 445 Ma). In addition to the dramatic loss of biodiversity, significant environmental change course such as redox conditions and nutrient availability have been the focus of debate. Previous studies have used isotopes of nitrogen (N) to reconstruct the redox evolution of the paleo-ocean and have identified biological nitrogen fixation as the main mode of nitrogen cycling during the OST. However, low δ15N values, ranging from -2‰ to +1‰, possibly correspond to four different redox conditions. The precise roles of these redox conditions and the spatial distributions of phytoplankton communities under different nitrogen cycles remain elusive. Here we present high-resolution nitrogen isotope, carbon isotope and lipid biomarker datasets from two drilled sections located on a submerged high of the Yangtze Basin to unravel the coupling between nitrogen biogeochemical cycling and phytoplankton community structure across the OST. The results suggest that there was a dominantly biological nitrogen fixation with local aerobic nitrogen cycling in the Yangtze Sea, and the nitrate inventory during the OST was smaller than that in the modern ocean. Particularly, before the Late Ordovician mass extinction (LOME), N-fixing cyanobacteria were likely extensively developed in the photic zone, while eukaryotic algae were limited. After the LOME, sea levels rose and the chemocline was higher than before the LOME. There was probably some NO3- that did not undergo denitrification in the surface ocean, favoring the development of eukaryotic algae. The ecological diversification from prokaryotic cyanobacteria to eukaryotic phytoplankton to eukaryotic zooplankton is likely to be a response to the enhanced biological pump, which generates positive feedbacks among the evolution of eukaryotic phytoplankton, organic matter enrichment, ocean oxygenation and atmospheric oxygen levels.

Depositional environment and mineralization mechanism of the gaint Ortokarnash manganese carbonate deposit in the Western Kunlun Mountains

Bang-Lu Zhang[1]*, Development and Research Center, China Geological Survey (zhangbanglu2008@126.com)
Yong-Sheng Li[2], Development and Research Center, China Geological Survey
Zhi-Cheng Lv[3], Development and Research Center, China Geological Survey

Abstract

The recently discovered Malkansu Mn carbonate metallogenic zone, in the West Kunlun Orogenic Belt, represents a significant breakthrough for economic prospecting in China. The Mn-mineralized intervals are stratigraphically continuous, with an average thickness of 6 *m, and are the highest-grade Mn carbonate ores (average Mn* >37% *by weight) identified in China to date.The Ortokarnash is the only ore body being actively mined, affording complete access to a continuous stratigraphic section of the underlying and overlying strata. Although previous work focused on the ore-controlling factors, geological features, and geochemical characteristics of the Mn ores in the Malkansu district, limited information is available on the mechanism(s) of Mn mineralization and the depositional environment. To aid in resolving both, we present the first comprehensive set of field and petrologic data, together with detailed geochemical analyses of both the Mn ore and associated host rocks of the Ortokarnash ore deposit. The Malkansu manganese carbonate metallogenic zone is hosted in the sedimentary rocks of the Upper Carboniferous Kalaatehe Formation, which is composed of three members: (i) the* 1*st Member is a volcanic breccia limestone; (ii) the* 2*nd Member is a sandy limestone; and (iii) the* 3*rd Member is a dark grey to black marlstone containing the manganese carbonate mineralization, which, in turn, is overlain by sandy and micritic limestone. Zircons from the volcanic-bearing breccia limestone and the interlayered tuff of the Kalaatehe Formation at Ortokarnash yield* $^{206}Pb/^{238}U$ *ages of* 322.9±1.8 *Ma and* 322.0±5.3 *Ma, respectively, which place the deposition of the manganese-bearing strata at the beginning of the Pennsylvanian (ca.* 323 *Ma). The manganese ore is dominated by fine-grained rhodochrosite (*$MnCO_3$*), dispersed in Mn-rich silicates (e.g., friedelite and chlorite), and trace quantities of alabandite (*MnS*) and pyrolusite (*MnO_2*). The size distribution (*>10 μ*m) and framboidal morphology of pyrite, low* $\delta^{34}S$ *values (*–16.18 *to* –5.28‰*), shale-normalized REE+Y patterns from the carbonate ores and associated rocks, and* ^{13}C*-depleted characteristics of the carbonate ores, were indicative of Mn(II)*

carbonates formed as a result of Mn(III/IV)-oxide reduction during burial diagenesis. This is consistent with the replacement of pyrolusite by rhodochrosite. The mineralization processes can be summarized as follows: During the transgression, dissolved Mn^{2+} upwelled to where the Mn(II)/Mn(III/IV) redoxcline intersects the seafloor, and Mn(III/IV) oxides were precipitated. Excess organic matter together with Mn(III/IV) oxide precipitates would have been buried and subjected to the microbial reduction of the oxide minerals. As a result, high concentrations of dissolved Mn^{2+} linked with carbonate alkalinity from the oxidation of organic carbon likely accumulated in the sediment porewaters, leading to conditions favorable for the formation of authigenic manganese carbonates. Besides, the marked strong positive Ce anomalies of the carbonate ores indicates the deposition rate of precursor Mn(III/IV) oxides are very slowly and these precursor Mn(III/IV) precipitates were chemically equilibrant with the ambient seawater. This slowly deposition rate may resulted from the dynamic glaciation in the south hemisphere Gondwana during the Late Paleozoic age (ca. 340–285 Ma).

OIL SHALE OF UZBEKISTAN - COMPLEX RAW MATERIALS OF MULTI-PURPOSE

MAKSUD ISOKOV[1]*, University of Geological Sciences (isokov.maksud1971@gmail.com)

Abstract

There is an increasing trend in the world to search for alternative raw materials sources of critical minerals, which are vital for modern high technologies. One of these alternatives is oil shale. The total reserves of oil shale, containing from 10 to 65% of organic matter on the globe, are estimated at 1,500 billion tons, including (in billion tons): in Africa 370, Asia 500, Australia 90, Europe 120, North America 220, South America 180.

Uzbekistan has deposits of Paleogene oil shale, which are complex multi-purpose raw materials. They are located in three regions of oil shale development: Gissar, Bukhara-Karshi region and Kyzylkum. Oil shale reserves in Uzbekistan are estimated by experts at 47 billion tons

Oil shale of Uzbekistan has the largest potential resources of hydrocarbon raw materials, as well as unique concentrations of Mo, Re, U, V, Au, Ag, platinum group metals, rare earths and other elements.

The studies carried out made it possible to establish the mechanism of concentration of industrially valuable elements in the original mineral-geochemical system, to identify carrier minerals, concentrators and forms of occurrence of industrially valuable elements V, U, Mo, Re, Au, Ag, platinoids, rare earths in oil shale for creating optimal technologies for their extraction.

The developed technology for processing oil shale makes it possible to obtain liquid and gaseous hydrocarbons through thermal decomposition (500-550ºC) without access to oxygen and metal-bearing semi-coke ash.

The subsequent chemical decomposition of the ash with various reagents made it possible to obtain metal-bearing solutions containing all these metals in different concentrations.

Analytical studies of ash showed that the contents of metals (molybdenum, vanadium) in oil shale of the Baysun deposit are significant and comparable to those of large and medium-sized deposits of these metals of other genetic types. The ash of oil shale occurrence Uchkyr-Kulbeshkak (Bukhara-Karsha region) contains: vanadium pentoxide – 0.34%; molybdenum – 0.072%; tungsten trioxide – 0.07%; rhenium – 0.6 g/t; uranium – 0.007%.

The ash of oil shale from the Sangruntau deposit contains vanadium pentoxide - 0.1-0.33%; nickel - 0.02-0.03%; cobalt - 0.001-0.002%; molybdenum - 0.01-0.073%; tungsten trioxide - 0.01-0.06%; rhenium - 0.0001-0.0002%, titanium - 0.30-0.49%. In the oil shales of the Aktau deposit, almost all metallic chemical elements were found in quantities close to or exceeding clarke ones, including lithophile (actinides were not determined), lithophile-chalcophile, siderophile-chalcophile and siderophile (including platinoids). The highest values, in descending order of degrees of concentration compared to the average content in the earth's crust, are given for rhenium, molybdenum, tellurium, selenium, cadmium, vanadium, bismuth, thallium, silver, nickel, zinc, lead, tungsten, copper, gold, antimony, chromium, rubidium, tantalum, thorium, hafnium,

samarium, lutetium, cerium, terbium, ytterbium.
The conducted studies made it possible to prove the significant contribution of metals to the overall geological and economic assessment of the development of oil shale deposits. This work is the first step towards diversifying certain industries of the Republic of Uzbekistan, taking into account providing them with alternative sources of mineral raw materials and energy resources.

Origin of Calcareous Concretion zone in the organic-rich Qusaiba Shale, Saudi Arabia

Mohamed Omar Abouelresh[1]*, King Fahd University of Petroleum & Minerals
(abouelresh@kfupm.edu.sa)

Abstract

Widely exposed zone of circular platy fossiliferous concretions dominated in the lower part of the Lower Silurian organic rich Qusaiba Shale, NW Saudi Arabia. Concretions are large and spherical or slightly flattened along the vertical axis. The identified zone of concretions also includes numerous large, commonly round or knobby, pale grey concretions up to 0.7 min diameter. Most of the existing concretions have a few millimeters, pale green outer rim caused by an enhanced content of clastic material. Both the oxygen and carbon isotope data show mainly negative values, revealing little difference between the values obtained from the cores and rims of the concretions. The range of δ18O values is rather wide (−14.4 to −2.6‰ PDB); the range of δ13C values is more limited (−5.0–0.2‰ PDB). However, the carbon isotope values for the calcite cement range between −5.0 and −3.7‰, with a mean value of −4.4‰ (PDB). For the septarian cracks, the δ13C values vary between −4.4 and −3.3‰, with mean value of−3.9‰(PDB). The preservation of successive accumulations of shells showing patterned distribution over much the same large area is taken as strong indication that the assemblages resulted from recurrent mass mortalities with relatively little disturbance by current action before burial. The cause of the mortalities is not known. Sparse evidence seems to favor burial under conditions of excessive turbidity and lowered salinity, possibly brought about by repeated influx of sediment-charged fresh water from rivers in flood.

The dominant lithofacies combination and genesis of the Kong2 shale in the Cangdong Depression of the Bohai Bay Basin

WEIHAO LA[1]*, China University Of Petroleum (East China) (jushrgs@gmail.com)
YUE SHI CHEN[2], China University Of Petroleum

Abstract

The K2 shale in the Cangdong Depression of the Bohai Bay Basin is a typical deep-lake to semi-deep-lake laminated shale formation, characterized by diverse mineral composition, high organic matter content, and abundant types of laminations. Influenced by early complex sedimentary environments, its lithofacies distribution is uneven, with significant differences between different lithofacies combinations. Therefore, conducting differential comparisons between different lithofacies in the study area to identify dominant lithofacies is of crucial importance. In this study, focusing on the K2 shale in the Cangdong Depression, lithofacies types were finely divided through core observation, thin section identification, X-ray diffraction, scanning electron microscopy, and other experimental methods. Differential comparisons were made based on lithofacies combinations, classified according to organic matter content, mineral content, and lamination type. The dominant lithofacies identified were argillaceous shale, mixed shale, and silty shale. Building upon lithofacies classification, major and trace element analyses, combined with core description and microscopic observations, were utilized to reconstruct sedimentary paleoenvironmental characteristics. Due to the Cangdong Depression being an inland fault basin, with overall climatic control predominating, differences in distribution are mainly attributed to terrigenous inputs and episodic sedimentation: under humid conditions, terrigenous debris from the basin margins enters the lake basin with surface water, resulting in stratification due to seasonal temperature differences, primarily forming laminated argillaceous shale and mixed shale lithofacies; under alternating wet and dry climatic conditions, increased salinity in the water body due to stratification and intermittent arid climate leads to the formation of laminated argillaceous shale and silty shale lithofacies; under arid climatic conditions, decreased terrigenous inputs and higher water salinity content primarily develop laminated and blocky silty shale lithofacies and mixed shale lithofacies.

Exploring CO2 Utilization Strategies in Shale: Enhancing Hydrocarbon Production, Sealing Efficiency, and Long-term CO2 Storage

Chioma ONWUMELU[1]*, University of North Dakota (anaesjudy@yahoo.co.uk)
Oladoyin Kolawole[2], New Jersey Institute of Technology
Ogochukwu Ozotta[3], University of North Dakota

Abstract

Shales, known for their low to ultra-low porosity and permeability, present a promising avenue for carbon dioxide (CO2) utilization in both CO2-enhanced oil recovery (CO2-EOR) and geologic CO2 storage (GCS). These rock formations, acting as source rocks, experience transformative induced diagenetic processes as they mature at greater depths, resulting in changes to their properties. Nevertheless, considerable gaps persist in our comprehension of CO2 utilization during thermal maturation and its viability for long-term CO2 storage.

This investigation explores the potential of CO2 utilization and storage within shale, particularly under in-situ conditions where thermal maturation is induced. It further delves into the implications of CO2 injection before maturation, specifically focusing on GCS and CO2-EOR. The Bakken and Green River shales were treated with supercritical CO2 and maturation to scrutinize their properties.

The outcomes divulged that early CO2 interaction with shales contributes to increased hydrocarbon production but compromises their mechanical strength as they mature. In contrast, CO2 treatment of already mature shales leads to alterations in their mineral composition and a decrease in total organic content. These revelations underscore that injecting CO2 into immature shales represents an immediate, practical choice for storage while concurrently enhancing CO2-EOR. Additionally, the proposed pre-maturation CO2 interaction process can rejuvenate mature shales, amplifying hydrocarbon production via CO2-EOR, improving their sealing capabilities, and mitigating long-term CO2 storage concerns.

This study provides critical insights that advance the deployment of CO2 utilization strategies in immature Bakken and Green River shales, particularly for GCS and CO2-EOR applications. As we strive toward the global net-zero objective by 2050, these findings pave the way for sustainable CO2 management and utilization in the energy sector.

The development characteristics of continental shale laminae in China and its petroleum geological significance

Jiankang Lu[1]*, China University of Petroleum, Beijing (1956656429@qq.com)
lianbo Zeng[2], China University of Petroleum, Beijing

Abstract

The development characteristics of continental shale laminae in China and their petroleum geological significance are investigated in this study. The abundant shale oil resources in China are primarily found in black shale formations dominated by continental lacustrine deposits, which exhibit a distinctive feature of extensive laminated structures. It has been observed during the practice of shale oil production processes that the presence of lamina structure significantly impacts reservoir quality, as well as the enrichment and production potential for oil and gas within continental shale formations. However, there is currently a lack of systematic studies on the characteristics and impact of laminae on hydrocarbon production. Therefore, this research focuses on various formations including Triassic Yanchang Formation in Ordos Basin; Qingshankou Formation from Paleogene era in Gulong Sag located within Songliao Basin; Upper Es4 and Lower Es3 Sub-member from Paleogene era situated within Jiyang Depression at Bohai Bay Basin; Permian Lucaogou Formation in Jimsar Sag; Permian Fengcheng Formation in Mahu Sag at Junggar Basin; Qianjiang Formation from Paleogene era present at Qianjiang Depression within Jianghan Basin. A comprehensive comparison was conducted regarding the characteristics and combination types exhibited by laminae across different sedimentary environments such as freshwater lakes, freshwater-brackish lakes, brackish lakes, saline lakes, saline-alkaline lakes, and saline-saline lakes. Furthermore, the microscopic pore structure features, fracture development patterns and material differences associated with lamina structures were analyzed. The results indicate that clay laminae and felsic laminae are the predominant types in freshwater and freshwater-brackish water environments, while carbonate laminae are not well-developed. Conversely, brackish water and saltwater lakes exhibit carbonate lamina as the primary type. In saltwater-alkali water and saltwater-salt lake environments, carbonate lamina is also dominant, accompanied by alkaline mineral lamina and salt lamina development. A statistical comparison of pore structure, fracture development characteristics, and measured physical properties between laminated shale and non-laminated shale in different aquatic environments was conducted. The findings reveal that laminated shale possesses superior pore structure characterized by a bimodal distribution primarily within the 2 ~ 100 nm range and > 10,000 nm range. Non-laminated shale exhibits a unimodal distribution mainly within the 2 ~ 100 nm range due to bedding fractures commonly found in laminated shale providing greater reservoir space for this type of rock formation. Additionally, laminated shale demonstrates higher porosity compared to non-laminated shale with values ranging from 1 to 2 times greater. The impact of laminar layer development on permeability is more pronounced as it significantly enhances reservoir seepage capacity horizontally. Layers exhibiting favorable physical properties offer increased space for oil and gas

seepage, facilitating their enrichment; thus, becoming key targets for continental shale exploration and development.This study provides an effective reference for reservoir evaluation and dessert optimization of continental shale.

Sedimentary Characteristics, Distribution and Development Control Factors of Lower Cambrian Marine High Organic Matter Abundance Shale in Lower Yangtze Area

Jun WANG[1]*, CNOOC China Limited, Tianjin Branch (varran@163.com)
Haifeng YANG[2], CNOOC China Limited, Tianjin Branch
Bo YANG[3], CNOOC China Limited, Tianjin Branch
Rucai ZHANG[4], CNOOC China Limited, Tianjin Branch
Xiaoling WANG[5], CNOOC China Limited, Tianjin Branch

Abstract

1 Study background

Lower Cambrian marine shale with high organic matter abundance (∈1) is developed in upper Yangtze area, which is the major source rock of Paleozoic Anyue giant gasfield with gas reserves over 1×1012 m3. In contrast, there is no major gas field discovered in lower Yangtze area due to lack of research and development of intense tectonic movement. In this study, Sedimentary characteristics, distribution and development control factors of ∈1 shale in lower Yangtze area are analyzed and there is bright prospect for gas exploration.

2 Structural environment

The ∈1 shale is deposited on the passive continental margin with transgression widely developed under the global greenhouse climate, and it is widely developed in the Yangtze plate. The distribution of ∈1 shale is mainly controlled by the structural pattern of "two basins and one shelf" (the northern Chuhe basin, the southern Qiantang basin and the middle Nanjing deep-water shelf) in lower Yangtze area.

3 Sedimentary characteristics and distribution

The thickness of ∈1 source rock in the northern Chuhe and southern Qiantang basins is over 400m and the TOC content is over 4%. The thickness of ∈1 source rock in the middle deep-water shelf is about 150m and the TOC content is about 3%. The carbon isotope of kerogen is lower than - 26 ‰, and the type of organic matter is type I-II. The average biogenetic barium contents of basin and deep-water shelf are 1583 and 203 μg/g respectively, reflecting high level of paleoproductivity, and V / (V + Ni) index ranges from 0.74~0.92, reflecting the reduction-sulfide environment. The ∈1 source rock with high organic matter abundance in the lower Yangtze area is mainly controlled by the high level of paleoproductivity and good preservation conditions.

The deep-water shelf ∈1 source rock in upper Yangtze Sichuan Basin is mainly developed in the Mianyang-Changning rift trough. The thickness of the ∈1 shale in the rift trough is simillar to that of the ∈1 in the lower Yangtze area, but the average TOC is just 2.17 %, lower than that in lower Yangtze area.

4 Development control factors

Low latitude greenhouse paleoclimate: the lower Yangtze are is located near the equator during the Early Cambrian, and the warm climate conditions are conducive to biological prosperity.

Frequent and widespread upwelling: upwelling in the lower Cambrian under the structural background of "two basins and one shelf" is widespread in lower Yangtze area, and upwelling can significantly improve the paleoproductivity of algae and form reduction environment conducive to the preservation of organic matter.
Input of terrigenous clasts: lower Yangtze area is far away from the ancient land, and this reduces the input of terrigenous clasts, which is conducive to the enrichment of organic matter. In contrast, the ∈1 shale in the upper Yangtze Sichuan Basin is mainly developed in the rift trough, far away from the upwelling and close to the ancient land. The high input of terrigenous debris dilute the organic matter of ∈1 shale, and accordingly the TOC content is lower.

Abstract

In order to solve the problems of unclear enrichment law of Gulong shale oil and difficult evaluation and prediction of sweet spots, Daqing Oilfield, through independent research, established the theory of in-situ reservoir formation of continental shale oil and the comprehensive evaluation technology of geological engineering "double sweet spot". By creating new experimental methods, It is clear that clay minerals can inhibit the conversion of organic matter, the water between clay layers can hydrogenate to reduce the disproportionation rate of crude oil, the ratio of light hydrocarbon to heavy hydrocarbon increases from 1:1 to 2:1. it is found that the Gulong shale kerogen → adsorbed oil → free oil formation evolution model, shale oil favorable formation window is Ro 0.9~1.6%. Nano-pores and foliation form a unique dual medium reservoir. it is found that pore throat gradually decreases from top to bottom, and displacement pressure increases. After Ro>1.3%, Pf <Pd, and forming a self-sealing mechanical reservoir. The theory of in-situ reservoir formation of continental shale oil was innovatively established. The correlation analysis between shale oil evaluation parameters and productivity shows that the higher S1 is, the higher the oil recovery intensity is. The higher the porosity of large pores characterized by nuclear magnetic, the higher the production of every kilometer of horizontal interval. The comparison of microseismic monitoring shows that high Young's modulus, high brittle mineral content, low foliation density and low fracture pressure section have larger compressive fracture height. Based on the core evaluation parameters of geology and engineering, the first geological engineering integrated dessert classification quantitative evaluation standard.The quantitative evaluation of shale oil sweet spot is realized, and the optimal evaluation of gold target layer is supported. The results won 13 patent granted for an invention, and two group company patent gold award, issued more than 10 standards. The forecast reserves of 1.268 billion tons and proved reserves of 204 million tons have been submitted,

effectively promoting the construction of a national demonstration zone, and it is expected to build the largest continental shale oil production base in China

Abstract

As the development of unconventional oil and gas resources progresses, shale oil occupies an increasingly important position in the global energy market. The study of reservoir spaces and crude oil occurrence characteristics in Jurassic shale oil reservoirs is crucial for assessing and enhancing the efficiency of shale oil and gas extraction. This research utilizes Confocal Laser Scanning Microscopy (LSCM) technology, employing high-resolution three-dimensional imaging techniques, to conduct a detailed analysis and study of the reservoir spaces and crude oil component occurrence characteristics in the Jurassic shale of the Sichuan Basin.

We collected shale samples from different lithofacies and conducted in-depth observations of their microstructures using LSCM technology. The study successfully revealed the three-dimensional characteristics of pore structures, organic matter distribution, and hydrocarbon occurrence states in the shale. The results demonstrate that confocal laser scanning technology can effectively identify micro-pores and fractures in the rock, as well as the complex interactions between organic components and inorganic minerals, providing a significant scientific basis for the assessment of shale oil and gas reserves and the formulation of effective extraction strategies.

Furthermore, based on the confocal laser scanning data, we have developed a three-dimensional visualization model of the shale oil occurrence state, enhancing our understanding of the microscopic occurrence mechanisms of shale oil. These research findings not only offer new scientific tools and methods for the exploration and development of unconventional oil and gas resources but also have significant theoretical and practical implications for optimizing shale oil and gas extraction technologies and improving resource utilization efficiency.

The innovative application of this research highlights the immense potential of confocal laser scanning technology in the field of shale oil geology research, paving new technical paths and perspectives for the exploration and development of future unconventional oil and gas resources.

A record of mixed carbonate and volcanic sediments in the foothills of Zelee and Geyser carbonate banks (NW Madagascar)

Dhishna BULJORE[1]*, Ifremer (dhishna.buljore@ifremer.fr)

Abstract

The northern Mozambique Channel, located in the southwest of the Indian Ocean, is impacted by climatic changes, such as changes in temperature, salinity and eustatism, which affect the production of calcium carbonate. Additionally, the NW area of Madagascar has experienced regional volcanism since the Tertiary period. This study focuses on Zelee and Geyser banks and enhances our understanding of the evolution of the reef productivity at glacial-interglacial frequencies. It also aims to estimate the impact of volcanism on coral reef growth and deep-sea sediment stacking since the Plio-Quaternary.

To establish an age model of one sediment core, stable isotopes (δ18O and δ13C) were measured on planktonic foraminifers (white Globigerinoides ruber). Other methods such as physical core logger (MSCL) and X-ray fluorescence spectrometry (WD-XRF) have allowed the identification of high magnetic susceptibility events containing volcanic particles within the almost fully carbonated stratigraphy. Furthermore, SEM images and EMP measurements helped to characterise the volcanic content.

The isotope stratigraphy and elemental components were compared to establish the relationships between aragonite and calcite productivity and isotope stages and associated past sea-levels. During periods of highstands, aragonite production is high, and conversely, during periods of lowstands, it is low. However, as the percentage of aragonite increases, the calcite percentage decreases. An inverse relationship is observed between these two minerals. The core records at least four glacial-interglacial events (MIS 8) and major volcanic accumulations that occurred during the Quaternary period. The first volcanic event recorded during the Holocene has been identified in other cores located in the northern Mozambique Channel, and is probably associated with volcanic activity on Mayotte. However, the older volcanic elements contain minerals with a continental origin, such as biotite, which suggests an origin from Madagascar.

There is a correlation between the growth of carbonate platforms and volcanism activity in the area, with a marked decrease in the percentage of aragonite deposited in relation to volcanic events. This can lead to a temporary interruption in the production of the reef at the time of the eruption on the platform due to a disturbance in the environment of the coral reef. It is followed by a significant increase in the percentage of aragonite shortly after the volcanoclastic deposits. The increase in carbonate production may be attributed to the resumption of reef production once the platform is submerged, resulting in a stack of carbonate sequences.

Abstract

Information regarding weathering in sedimentary rocks is mainly carried by the terrigenous component, comprising sediment particles formed during weathering, which are subsequently eroded, transported, and deposited in sedimentary basins. The degree of chemical weathering of the terrigenous fraction can be estimated using different weathering indices. However, sedimentary rocks typically encompass detrital and various authigenic and/or biogenic phases that mute the weathering estimates. In marine sediments, particularly in tectonically active basins, aside from authigenic-biogenic phases, varied amounts of pyroclastic material occur either dispersed or as distinct tephra/tuff layers. These materials can introduce significant bias into detrital material source area weathering estimates but quantifying dispersed ash from detrital terrigenous and/or authigenic components poses challenges. Our research focuses on the Upper Ordovician carbonate deposits of the Baltic Basin containing numerous altered volcanic ash layers (bentonites) indicative of past volcanic activity during the background sedimentation. Our aim is to unravel the amount of volcanic material dispersed in sediments and its influence on the chemical weathering indices.

Geochemical analysis shows that the influence of volcanic material extends beyond the discrete bentonite layers, and volcanic material is dispersed throughout the limestone strata, comprising a substantial portion of sedimentary rocks (up to 50-90%). The presence of the volcanic component in sediments significantly influences weathering intensity estimates in the terrigenous fraction, and intervals with higher volcanic components exhibit significant variability in chemical index values, depending on the dominant authigenic silicate mineralogy — phyllosilicates (smectite and mixed-layer illite-smectite) or K-feldspar.

This implies that interpretations of weathering regimes and intensities in sedimentary sequences, particularly in active margin settings, should be carefully analyzed for potential impacts from pyroclastic material. The terrigenous fraction of the Upper Ordovician sediments in the Baltic Basin, corrected for volcanic components and diagenetic K addition, suggests an intermediate weathering level consistent with the paleocontinent Baltica's position at southern paleolatitudes between 40-30°S during the Katian. Interestingly, the corrected weathering intensity does not exhibit any changes in the interval with several thick bentonite beds or in sediments immediately above, indicating that even if a cooling effect related to intensified volcanism occurred in the Upper Ordovician, it was either too weak or too short to exert a measurable influence on weathering intensity.

Abstract

The present work investigates the intimate relationship existing between lava effusion rate, water-lava interaction and accumulation of hyaloclastites considering the Aci Castello hyaloclastite deposits of Mt. Etna. The emplacement of pyroclastic layers in various non-explosive volcanic settings is considered, in fact, primarily triggered by interactions between water and lava. Nevertheless, such interactions can occur at different level, depending on effusive rates, and control the generation of hyaloclastic deposits different in stratigraphic and microtextural characteristics. The present case study comprises an effusive facies, composed of pillow basalts, and an explosive facies in which of hyaloclastic beds includes basaltic fragments and muddy rip-up clasts within a reddish groundmass, emplaced in a submarine fan-like architecture. Therefore, the combination of fieldwork, petrographic analyses, paleomagnetic and 3D model rendering using GIS, allowed the three-dimensional reconstruction of the volcano-sedimentary architecture, investigating macro- and microscale properties of the entire body. Beyond the stratigraphic observations in the field, both facies have been analyzed in thin sections as well as at the XRD. Pillow basalts show a microcrystalline dark brown groundmass wrapping phenocrystals of plagioclase and pyroxene. Hyaloclastites are predominantly constituted of loose crystals and basaltic fragments in a yellow, glassy, vesiculated groundmass, indicating sintering processes soon after the hyaloclastite emplacement. Muddy rip-up clasts consist of quartz, calcite and clay minerals. Paleomagnetic analyses on feeder dykes indicate the original orientation of the architecture. 3D modelling allowed the reconstruction of the prograding fan-like body, where basaltic and hyaloclastic layers are interdigitated together, and the suggestion that alternations of basaltic and hyaloclastite emplacement seems to be controlled by effusive rates at which magmas reached the surface, beyond the magma-water interaction.

Abstract

The Qiantang Sag, located within the East China Sea Shelf Basin, harbors substantial Mesozoic strata, yet its sedimentary characteristics have remained underexplored, obscuring the full spectrum of the region's geological history and resource potential. This study hones in on the Cretaceous period of the Qiantang Sag, unveiling a nuanced multi-phase sedimentary model to chart the sag's depositional evolution influenced by volcanism. Employing an integrated analysis of drilling, core data, and seismic interpretations, we pinpoint a predominant development of alluvial fan and braided river deposits within an arid to semi-arid climate during the Cretaceous. Notably, detrital zircon U-Pb dating illuminates the Zhe-Min Uplift as a crucial provenance, offering insights into sedimentation timelines and source dynamics. By correlating vertical sedimentary sequences with provenance data, our research delineates sedimentary frameworks, paving the way for a reconstructed paleo-depositional narrative across diverse geological epochs. During the Early Cretaceous Yushan Period, the region was influenced by intense volcanic activity, while also developing alluvial fan deposits in an arid environment. The Late Cretaceous Minjiang Period was characterized by semi-arid alluvial fan and braided river deposits. In contrast, the subsequent Shimentan Period saw the development of similar deposits, with the possible addition of seasonal lake deposits. This study not only bridges critical gaps in our understanding of the Qiantang Sag's sedimentary processes but also amplifies the geological blueprint for resource exploration in the East China Sea Shelf Basin.

Abstract

Whole-rock Samarium-Neodymium and Strontium isotope compositions of twenty four samples of fine-grained clastic rocks (shales, siltites, mudstones) from the eastern Parnaíba basin, Northeastern Brazil. Major and trace element compositions of nineteen of these samples are also presented. The studied samples were collected from outcrops of the Paleozoic Canindé (Pimenteiras, Longá and Poti) and Balsas (Piaui Formation) groups, and from the Jurassic Pastos Bons Formation. The latter unit is younger than the intraplate tholeiitic magmatism referred as CAMP – Central Atlantic Magmatic Province and locally as the Mosquito event. Discrimination diagrams based on more immobile trace elements such as Th, Sc, La and Zr indicate sedimentary provenance from predominantly felsic sources, with high degrees of crustal recycling. PAAS-normalized REE diagrams show that the Pimenteiras and Longá Formations display flat patterns with slight REE enrichment, and initial εNd and 87Sr/86Sr around the average composition of the upper continental crust, respectively between -8.9 and -14.6 and between 0.711 and 0.760, indicating provenance from old Precambrian basement. The Nd TDM model ages of the Pimenteiras between 1.32 Ga and 2.00 Ga indicate heterogeneity of source areas during the Devonian, and TDM ages around 1.6 Ga in the Longá Formation samples suggest intense recycling of older sediments. The Poti formation samples yield TDM ages of 2.30 Ga and 2.32 Ga, respectively, suggesting tectonic reactivation and new input from Archean-Paleoproterozoic basement complexes. The Pastos Bons Formation samples show lower Th-Sc ratios, light-REE depletion, and less negative initial εNd, indicating contribution from mafic rocks, probably from the underlying Mosquito Formation intraplate tholeiitic basalts and dolerites.

Abstract

In the last three decades, the assessment volcanic impact on modern sedimentary systems and ancient sedimentary records has become of fundamental importance in the Earth Science community. Eruptions, in fact, are one of the few geological phenomena shaping the Earth observable on human time scale, and their impact on the environment can be directly investigated through time. Nevertheless, there is a paucity of data showing how major volcanic eruptions can impact the environments surrounding volcanic centres during time. With the aim of partially filling this gap, this work has been designed to highlight the environmental modifications occurred and still occurring on fluvio-lacustrine environments after the Plinian eruption of the the Puhyeue-Cordón Caulle (VEI 5). Through the analysis of satellite images in GEE (Google Earth Engine), the reconstruction of climatic series and the built of a GIS database for geostatistical analyses, it has been designed a workflow that quantifies the sedimentary modifications occurred and still occurring around the volcano under climatic control, with particular focus on fluvial drainage patterns (Golgol river) and lacustrine sediment repository (an area of about 26.0 km^2). Both on the southwestern and southeastern sides of the volcano, deltaic systems prograded since the eruption year, with a net increase in progradation rate since 2015. The Golgol river partially became a braided river due to the abrupt discharge of large volumes of tephras for around seven years, with an impacted area of about 1.0 km2. Lacustrine systems connected to hydrographic basins downwind with respect to the eruptive column in the southwestern part of the volcano experiences a net increase in the quantity of suspended sediments, which directly impacted the turbidity of the waters for a couple of years, as well as a net progradation of deltas and coastal deposits. All these findings better delineate in which way mid-latitude environments response to a Plinian eruptive event, with a particular focus on a time series of 13 years.

Petrological, Geochemical, and Depositional Characteristics of Early Proterozoic Tuffs of Gwalior Basin, Central India

SHIKHA DIXIT[1]*, CSIR-National Geophysical Research Institute (shikhadixit288@gmail.com)
Sreenivas Bulusu[2], CSIR-National Geophysical Research Institute
Teeda Vijaya Kumar[3], CSIR-National Geophysical Research Institute
Gugulothu Balu[4], CSIR-National Geophysical Research Institute

Abstract

The Gwalior Basin is one of the Paleoproterozoic basins in Central India, located in Madhya Pradesh in the northern part of the Bundelkhand craton. Many researchers worked out the details of lithostratigraphy. Among the litho units of the basin, the Morar Formation of the Paleoproterozoic Gwalior basin is of particular interest as it hosts numerous tuffaceous sequences that have not been the focus of research. Tuffaceous rocks (pyroclastic) represent a considerable thickness of 8 to 10m and are well-developed around the Birauli section. In addition, the Morar Formation has a carbonate-argillite sequence and well-developed BIF sequences. In this study, we report the petrographic and geochemical characteristics of the tuffaceous rocks from the Birauli section.

The petrographic studies of the tuffs indicate that the quartz grains are angular in shape, embayed quartz with uniform extinction, and crystal shards, pointing to possible volcanic origin. Further, accessories like minerals like pyrite, zircon, and anatase are identified.

The major element compositions of the Birauli tuffaceous rocks show that the ratio of SiO_2/Al_2O_3 ranges from 7.51 to 19.69 (average 14.02%), and the TiO_2/Al_2O_3 varies between 0.019 and 0.063 (average 0.035%), indicating that they have parentage of felsic magma.

The trace element analysis of these tuffaceous rocks shows that the total rare earth element (∑REE) concentrations range from 26.44 to 245.25 ppm (average 102.06 ppm). The chondrite normalized REE distribution of Birauli tuffs shows LREE fractionated with flat HREE patterns. The Eu anomalies range from 0.38 to 1.91 (average 1.20), suggesting a mild positive to negative Eu anomaly. Further, the tuffaceous rocks show positive anomalies in Rb, Nd, Ba, and Pb and negative anomalies in Nb, Sr on primitive mantle normalized trace elemental spider diagram. The geochemical compositions of the Birauli tuffs suggest that the parental magma from which these tuffs are derived is of rhyolitic composition. As no vent could be recognized within the basin around Birauli, it is suggested that the source could be extra-basinal and deposited as ash fall tuffs.

Abstract

This work investigates the composition of four beaches located around the Island of U (Jeju Island – Republic of Korea). Island sedimentary processes are strongly controlled by wind-driven waves, strong tidal currents, winter storms and seasonal typhoons. Field observations, sedimentological analyses, petrographic point-counts on thin sections and scanning electron microscope investigations were conducted in order to understand mechanisms leading to the generation of particles and their accumulation in tidal-dominated beaches under the aforementioned factors. Beaches located in the nearby of tuff cones are predominantly volcanic-derived, beaches laying on lava substratum or in flat areas are predominantly composed of carbonates. The volcanic epiclastic fraction of sands is predominantly composed of lithics and minorly of single minerals and derived from pyroclastic sequences forming the island tuff cones. In contrast, the bioclastic fraction is primarily composed of fragments of rhodolites and mollusks, followed by minor amounts of echinoderms, benthic foraminifera and bryozoan. In addition, some beaches are predominantly formed of pebble- to cobble-sized detritus of rhodolites. These rhodolites are mainly composed of aragonites and high-magnesium calcite, and often nucleated around volcanic particles. Preliminary results indicate that volcaniclastic sequences are more prone to disaggregation, generating the almost total volumes of volcanically-derived beach sand fraction. Nevertheless, such production of particles often becomes minor with the respect to bioclastic sand generation controlled by climatic and oceanic dynamics, resulting in the progradation of carbonate beaches on a volcanic substrate. Understanding generation and depositional processes of these beach sands provide valuable insight into the coastal evolution of U Island, and contributes to the comprehension of the relationship between volcanic and carbonate sediment production.
This work was supported in part by the Italian Ministry of Foreign Affairs and International Cooperation, grant number KR23GR08.

Pengjie Ma[3], 17561665156
Chunmei Dong[4], 159208965601
Yuqi Wu[5], 15314318221

Abstract

The rapid lithofacies transitions and compositional heterogeneities inherent in lacustrine shale posed significant challenges to accurately characterizing it, thus impeding the optimization of shale oil exploration and extraction. This study employed a multifaceted methodology to address these obstacles, integrating principal component analysis (PCA), K-means clustering, and geochemical trend analysis to precisely identify and characterize nine distinct chemofacies. A comprehensive analysis of petrological characteristics and depositional environments was accomplished by examining core samples, thin sections, scanning electron microscopy (SEM), mineralogical compositions, and total organic carbon (TOC) content. The identification of favorable locations was supported by meticulously considering variables, including TOC, porosity, permeability, and the mineral brittleness index (MBI). This investigation revealed the presence of nine distinct chemofacies within the targeted layer. Specifically, Chemofacies 5, characterized by calcite vein laminations, was identified within Unit 2 parasequence, and Chemofacies 6, enriched with feldspar-quartz mineral laminations, was located within Unit 4 parasequence. Both chemofacies exhibited elevated TOC, enhanced porosity and permeability, and favorable brittleness, qualifying them as ideal sweet spots for shale oil exploration. The insights from this study align with the characteristics of traditionally optimal reservoirs, validate the robustness of the employed methodologies, and carry significant implications for the accurate prediction of terrestrial shale oil sweet spots in future explorations.

Diagenetic Evolution of Coal Beds in the Sabinas Basin, NE Mexico: Insights from Fluid Inclusions Geochemistry, and Stable Isotope (δ18O, δ13C, and δ34S) Analysis

SUMIT MISHRA[1]*, Instituto de Geociencias, Universidad Nacional Autónoma de México, México (smpsgeo@geociencias.unam.mx)
Eduardo González Partida[2], Centro de Geociencias, Universidad Nacional Autónoma de México, México
Joseph Madondo[3], Centro de Geociencias, Universidad Nacional Autónoma de México, México
Genesis Arelly Ramos Garcia[4], Centro de Geociencias, Universidad Nacional Autónoma de México, México

Abstract

The Sabinas coal region accounts for over 90% of Mexico's total coal production. The basin spans about 37,000 square kilometres, and its geological formation is linked to the formation of the Proto-Gulf of Mexico and its subsequent "tectonic closure" with the Laramide Orogeny. The basins are delimited by structural elevations such as the Coahuila Peninsula, the Burro-Peyotes platform, the Tamaulipas arc, and faults such as La Babia and San Marcos. The Olmos Formation also referred to as the "Coal Formation," was formed in a basin through two distinct periods. Firstly, there was a marsh environment with abundant flora, which led to the deposition of peat with varying thickness and quality. Secondly, there was a continental and transitional environment, including upper intertidal areas, marginal lagoons, swamps, and alluvial plains. The Upper Cretaceous deltaic system in question has been characterised as such through the use of palaeobotanical, pollen, and spore investigations. These studies have determined that the system existed in a subtropical climatic setting. We have found some new information about fluid inclusions in diagenetic calcites that are linked to coal. We also have found stable isotopes (18O, 13O, and 34S) in calcites, pyrites, and marcasites. The fluid inclusions exhibit homogenization temperatures ranging from +82 ºC to +143 ºC and final ice fusion temperatures ranging from -3.1 ºC to -1.1 ºC. These temperatures correspond to a salinity of 1.9% to 5.4% (mean of 2.2) in terms of the equivalent weight percent of NaCl. The sulphides have δ34S ‰ values ranging from +7.5 ‰ to +20.0 ‰. Calcite found in coal exhibits a carbon isotope composition (δ13CvPDB ‰) ranging from -7.87 ‰ to -11.11 ‰. The oxygen isotope composition (δ18OvPDB ‰) of the same calcite ranges from -5.01 ‰ to -11.80 ‰, whereas the oxygen isotope composition (δ18OvSMOW ‰) ranges from +18.75 ‰ to +25.74 ‰. The vitrinite reflectance values documented in the literature for coal expressed as a percentage of Ro, vary from 0.5 to 1.5. We found that the coal in the Sabinas Coal Basin matured in a temperature range that is within the catagenesis evolutionary zone. This was determined by analysing diagenetic calcites. The presence of mature organic material (such as upper plants and raw coal) can be inferred from the isotopic behaviour of sulphur dioxide and carbonate in a closed system. This system involves the circulation of deep meteoric water, which promotes the reduction of sulphates to sulphide. The

isotopic fractionation during this process is limited and can be classified as closed-basin diagenetic sulphides. The carbonate species observed are a byproduct of secondary organic matter, which underwent a final decarbonisation process at greater burial depths in the presence of CO2 derived from organic.

Reservoir characteristics and formation mechanism of the Lower Cretaceous Laiyang Group deep-water tight sandstone in the Lingshan Island, Eastern China

Tongtong CHEN[1]*, School of Geosciences, China University of Petroleum (East China) (chenttupc@126.com)
Yaoqi ZHOU[2], School of Geosciences, China University of Petroleum (East China)
Hanqing LIU[3], School of Geosciences, China University of Petroleum (East China)
Ruiyang LIU[4], State Key Laboratory of Continental Dynamics, Department of Geology, Northwest University
Junru Gao[5], Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

Deep-water sandstone reservoirs of the Laiyang Group are developed in the Lingshan Island; however, due to the lack of in-depth understanding of microscopic characteristics and reservoir genesis, the exploration and development process of oil and gas resources in this area has been hindered. Combined with field outcrop observation and core data, the features of tight sandstone reservoir of the Laiyang Group were systematically characterized and controlling factors of reservoir development were discussed by means of casting thin sections, XRD analysis, scanning electron microscopy (SEM), physical property test and low-temperature nitrogen adsorption. The research results show that the tight sandstone is dominated by fine-grained lithic feldspar sandstone and feldspar lithic sandstone, with porosity ranging from 0.18% to 3.20%, and permeability ranging from 0.002 mD to 2.965 mD, which belongs to ultra-low porosity and ultra-low permeability reservoir. The reservoir space includes primary intergranular pores, secondary dissolution pores, intercrystalline pores and fractures. Within 100 nm range, the mesopores (2~50 nm) of sandstone samples, groove pores composed of flake particulate material, are relatively developed; the specific surface area of sandstone samples ranges from 0.360 m2/g to 2.772 m2/g, the total pore volume ranges from 0.001468 ml/g to 0.005878 ml/g, and the average pore diameter ranges from 8.483 nm to 18.672 nm. The reservoir quality is mainly controlled by sedimentation and diagenesis, that is, the deep-water low-energy sedimentary environment is critical for rocks with fine grain size, high matrix content and poor original physical properties. Strong compaction leads to the destruction of a large number of primary intergranular pores; the cementation of calcite, authigenic quartz, clay minerals, pyrite and albite eventually results in the densification of the rock. In particular, compaction and cementation of carbonate and clay minerals are the key to the tight reservoir in the study area.

The features and mechanisms of coral reef carbonate weathering since Miocene: evidence from Yongle Atoll in the South China Sea

Yang YANG[1]*, Guilin University of Technology (yangyang007@glut.edu.cn)
Kefu YU[2], Guangxi University
Xijun LIU[3], Guilin University of Technology

Abstract

Carbonate weathering is a crucial component of the global carbon cycle, however, the processes, influencing factors, and formation mechanisms remains unclear. Coral reef carbonate are ideal research materials due to their successive deposits, limited later reformation, susceptibility to weathering and ease of dating. Thus we focuses on a 928.75-m-long coral reef core (CK2) from Yongle Atoll in Xisha Islands, northern South China Sea, and study the features and mechanisms of coral reef carbonate weathering by petrological and geochemical methods. Compared with the white coral reef carbonate formed under normal environment, the weathered carbonate are usually yellow, brownish yellow and maroon red. In addition, voids and dissolution pores are abundant, the surface of these pores are mostly covered with calcareous crusts and clay mud-like materials, and some of the holes develop stalactite-shaped crystals. Besides, the weathered carbonate usually exhibit the following geochemical anomalies, with a sudden jump increase of 87Sr/86Sr, a simultaneous negative bias of δ13C and δ18O, an increase in content of Mn, Ti, Zr, Al, Si, K and Fe, and decrease in Sr. Based on the above consensus, 13 weathered coral reef carbonate strata are identified, and can be divided into three types according to their petrological and geochemical characteristics. The first type exhibits only a geochemical anomaly without any petrological anomaly. These strata mainly consist of rounded blocks and sand debris. We speculate that the coral reef stratum is composed of blocky reef-building organisms and filling sand in a grid structure. This structure collapses easily when the strata are exposed to suffer karstification, most of the sand and small blocks are washed away, while the remaining blocks are rounded by the waves. This type indicates that the species of reef-building organisms can influence the coral reef carbonate weathering by control the structure of the coral reef. In the second case, there is only a petrological anomaly without any geochemical anomaly. These strata usually appear for a short period and are thin. The coral reef carbonate in these strata is dense and mostly composed of massive corals. In this case, it is difficult to form a phreatic layer in the strata, which is necessary for the geochemical exchange between meteoric water and the surrounding coral reef carbonate. This type further confirms the influence of reef-building organisms on weathering.The third type exhibits both petrological and geochemical anomalies simultaneously. These strata are usually form in warm climates, and are the result of a combination of climate and hydrology. In comparison to previous studies on coral reef carbonate weathering, which mainly focused on the lateral and vertical control of hydrologic factors, this study places more emphasis on the influence of climate and species of reef-building organisms.

LITHOLOGICAL PROCESSES ON THE EXAMPLE OF THE DONETSK COAL BASIN OF UKRAINE

Volodymyr Andriyovych BARANOV[1]*, M.S. Polyakov Institute of Geotechnical Mechanics of the National Academy of Sciences of Ukraine, Dnipro, Ukraine (andreevich7526@i.ua)

Abstract

In the north-east of Ukraine is the Donetsk coal basin (Donbass), which is part of the Dnieper-Donets Basin stretching from the Carpathian Mountains to the Caspian Sea. Donbass has been developed since the end of the 18th century. The uniqueness of this basin is that it contains deposits of all stages and substages of lithogenesis, except sedimentogenesis. It processes all grades of coal: from brown coal to anthracite. The rocks and processes occurring in this basin have been well studied. A large number of new phenomena and patterns have been described previously. The author of this work has been studying thermogasdynamic processes in the mines of this basin for more than 40 years. Some research results will be listed below.

At the end of the last century, a method of side illumination under an optical microscope was developed. Using this method, it is possible to study all microdeformations in rock-forming minerals. It is especially effective to use this method in the sandstones of Donbass, which consist of 50-60% transparent quartz. Using this method, all existing plastic microdeformations were described in detrital quartz grains of Carboniferous sandstones: Boehm stripes, plates and deformation belts, crumpled quartz, irrational twinning, blocking, granulation. Two new types of microdeformations were described: translational slip bands and “tabular” quartz. Studies of microdeformations made it possible to develop a plasticity coefficient - Kpl, mm-1 and a damage coefficient - Kd, %. These indicators make it possible to determine the relative degree of tectonic stress in the mountain range.

At the same time, the phenomenon of gas dissolution in minerals with increasing temperature and pressure was described; the appearance of inclusions with geometric shapes. These patterns made it possible to develop a method for determining paleotemperatures in sedimentary rocks without the use of coal. It was found that each grade of coal has its own paleotemperature of formation with a step of approximately 20 degrees of Celsius.

In 1984, the property of substances of different systems to form quasicrystals under the influence of changing thermodynamic, biochemical, physical-mechanical and other conditions was established. The study of this phenomenon made it possible to establish the reasons for the formation of suture and stylolite deformations in various rocks, which is very important when searching for oil and gas fields. Quasicrystals are considered as a transitional form of matter between its crystalline and amorphous states.

The study of thermogasdynamic processes in coal-bearing deposits of Donbass made it possible to describe the complete triune thermogasdynamic process: emission-explosion-ignition and truncated processes: explosion-ignition, emission-ignition. In the sediments of Donbass there are many emissions of coal and gas, as well as coal-hosting sandstones and gas. These problems are

also relevant in other countries with developed coal industries.

Role of the initial texture of carbonates on dolomitization propagation from 4D Xray tomography

Abstract

Dolomitization is a mineral replacement phenomenon that occurs in most carbonate platform and in foreland basins. In the latter context, the development of very large dolomite geobodies with a seemingly rather limited magnesium supply from hydrothermal fluids that migrate along and within faults during the orogenic contraction, is a long-term puzzle for the community: the so-called “dolomite problem”. One of the missing pieces of this puzzle is the lack of understanding of the kinetics of dolomitization, especially at low pressure and low temperature. On the experimental field, recent developments enabled the possibility of producing dolomitization from calcite in a controlled environment within a few days to a few weeks. This contribution presents a 4D evolution of the dolomitization fronts obtained from reacting carbonate calcium samples with different initial texture and porosity values. Carrara Marble, Oostones and Chalk were reacted at 200°C, 16 Bar with a Mg-rich, Zn-boosted brine in a closed environment, for 3 days to 3 weeks. The reaction was stopped at different times of the experiment by extracting and drying the sample, in order to scan it by the mean of 3D tomography, before reacting again for another period of time. Repetition of this protocol returns with an unprecedented 4D view of the propagation of the dolomitization front, in a volume where the porosity evolution can be monitored throughout the reaction. Results demonstrate that the initial texture has a primordial role on the replacement propagation speed, with a front penetrated much deeper at a given time in porous Oostones than in Chalk or in tight Marble. This impact is greater even than the availability of Mg in the system, as Mg-rich Calcite do not react faster than pure calcite. Our work validates that the role of chemical gradient is key to initiate and propagate the dolomitization in calcite, and provide new insights on how dolomite geobodies can be that voluminous in nature in spite of limited reactant supply.

Cyclicity related to solar activity in lacustrine organic-rich shales and their significance to shale-oil reservoir formation

Miruo LIN[1]*, China University of Petroleum (East China) (upc_linmiruo@163.com)
Kelai Xi[2], China University of Petroleum (East China)
Yingchang Cao[3], China University of Petroleum (East China)

Abstract

The formation mechanism of micron- to centimeter-scale sedimentary cycles in lacustrine shales is a hot topic of research, because these small-scale sedimentary cycles significantly influence shale-oil distribution heterogeneity. High-frequency paleoenvironmental evolution is an important controlling factor for the formation of small-scale sedimentary cycles. However, the driving factors of high-frequency paleoenvironmental evolution and the formation process of sedimentary cycles under its constraint remain speculative. In this study, which focuses on lacustrine shales, we find that the alternating deposition of variable thickness of organic-rich lamina (ORL) and silty-grained felsic lamina (SSFL) form sedimentary cycles on the micron to centimeter scale in the Chang 73 sub-member of the Yanchang Formation in the Ordos Basin. Based on detailed petrographic characterization, in-situ geochemical parameter testing, and high-resolution cycle analysis, the formation process of cyclical sedimentary records and related paleoenvironmental evolution are investigated. Three solar activity cycles were identified from the shales, namely the 360–500 yr, 81–110 yr, and 30–57 yr cycles (cycles I, II, and III, respectively). High-frequency paleoenvironmental evolution caused by solar activity induced lake-level fluctuation, which further controlled silty-grained sediment deposition and organic matter preservation in deep lake areas. Cycle I controlled relatively long-term lake-level fluctuation, driving several pairs of SSFL and ORL deposition at the centimeter scale. Cycles II and III were short-term cycles and acted on the millimeter to micrometer scale, further complicating the sedimentary strata forming during the period of lake-level fall induced by cycle I. The cyclic deposition of SSFL and ORL correspond to cycle III. Lake-level fluctuation influenced by cycle II mainly caused SSFL thickness variation in each lamina couplet. During the period of lake-level rise induced by cycle I, periods of lake level rise during cycles II, and III show cyclic variation in reducibility, and are not thought to control the supply of coarse-grained sediments in to the deep lake areas. Frequent lake-level fluctuation promotes lamina couplet formation in thickly-bedded shales, which creates favorable conditions for shale-oil accumulation. Oil produced from ORL can migrate-locally into dissolved feldspar porosity in SSFL and therefore is able to accumulate in shales, which creates high potential for future oil exploration in thickly-bedded lacustrine shales.

Paleoenvironmental Conditions of the Huayacocotla Basin, Mexico, During the Late Jurassic: Implications for Mn accumulation

Abstract

The mechanism by which manganese accumulates in sedimentary Mn carbonate deposits remains debated. Mexico hosts some of the worlds largest black shale hosted Mn deposits in the Molango district of east central Mexico, providing an excellent opportunity to reassess the current models of their genesis. In order to explore the conditions of formation of the Molango manganese deposits, we present an integrated paleoenvironmental reconstruction of the deposits through redox proxies (U/Th and V/Cr) and redox sensitive trace elements (M, U and V), carbon and sulfur isotopes, and organic chemistry (TOC) of manganese carbonate beds of the host Chipoco formation and the underlying black shales of the Santiago Formation in the Huayacocotla Basin, east central Mexico. Our results indicate that Mn (II) was accumulated under anoxic (possibly euxinic) conditions in basin center settings. Euxinia resulted from the inflow of anoxic waters from the Gulf of Mexico and enhanced by restricted water circulation in the basin. Redox conditions as well as the Fe-Mn redox cycling were hydrologically controlled by the episodic ventilation of the bottom waters due to the inflow of seawater from the open ocean. Mn (II) was sourced from both continental and hydrothermal sources and concentrated in the bottom waters due to the operation of a Fe-Mn shuttle across a redox stratified water column. Organic matter degradation led to 12C-enriched dissolved inorganic carbon that was precipitated in Mn carbonates on the basin floor. Mn carbonated deposition occurred during diagenesis via the coupled oxidation of organic matter and reduction of Mn oxides during episodic ventilation of the bottom waters, similar to what occurs in the Baltic Sea. Manganese accumulation in the Huayacocotla Basin was significantly influenced by both local and global environmental factors.

Selective Dolomitization and Its Influence on Reservoir Heterogeneity of the Lower Cambrian Longwangmiao Formation in Sichuan basin, South China

Xuefei YANG[1]*, Southwest Petroleum University (yangxf_swpu@163.com)
Hao TANG[2], Southwest Petroleum University
Chao CHEN[3], Southwest Petroleum University
Xingzhi WANG[4], Southwest Petroleum University

Abstract

Through field observation, thin section identification, cathodoluminescence, scanning electron microscopy observation (SEM observation), and geochemical characteristics analysis, we have conducted a comprehensive study on the selective dolomitization of the Lower Cambrian Longwangmiao Formation and its influence on reservoir heterogeneity in the northeast Sichuan Basin. Results indicate that the Longwangmiao Formation is composed of limestone, mottled dolomitic limestone, and dolomite from top to bottom. The mottled dolomitic limestone primarily consists of dolomicrite and powder crystal dolomite with anhedral to subeuhedral crystal shapes. Under cathodoluminescence (CL), these rocks exhibit dull red luminescence. In contrast, the limestone matrix is composed mainly of micritic limestone and micritic bioclastic limestone, which do not luminesce under CL. The dolomite mottle has a relatively high content of Na, K, and low Sr, Fe, Mn content compared to the limestone matrix. Notably, its Mg2+/Ca2+ ratio is lower, and MgO exhibits a negative correlation with CaO. The rare earth element (REE) characteristics of the dolomite mottle indicate the loss of light rare earth elements (LREEs) and the enrichment of heavy rare earth elements (HREEs), with an obvious negative Ce anomaly. The δ13C and δ18O values of the dolomite mottle are more positive than those of the limestone matrix and exceed the Early Cambrian normal seawater values. Combined with regional sedimentary background, petrology characteristics and geochemical analysis, it can be concluded that dolomitized fluids of mottled dolomitic limestone in Longwangmiao Formation originate from evaporated seawater with medium salinity. During the Late Longwangmiao period, as sea-levels continuously declined, seawater evaporated and concentrated to form medium salinity seawater, which caused the dolomitization during seepage reflux. Due to insufficient sources of dolomitized fluids, selective dolomitization preferentially occurred along biological burrows, leading to the formation of mottled dolomitic limestone. Intercrystalline pores and intercrystalline dissolved pores are developed in the dolomite mottle, leading to significantly higher reservoir porosity compared to dense limestone matrix, which results in enhanced reservoir heterogeneity. Distinct from mottled dolomitic limestone found in the northern Sichuan Basin, mottle dolomite reservoirs in the central Sichuan Basin have been completely dolomitized but exhibit strong reservoir heterogeneity caused by bioturbation. For the burrow, it contains numerous pore spaces that have been filled with bitumen and reflect as black mottle; however, for the dense matrix, there are fewer pores that reflect white mottle. The mottle shape and structure look similar to that of mottle dolomitic limestone found in the northern Sichuan Basin. Therefore, we believe that bioturbation is key to

forming the mottle structure in the Longwangmiao Formation within the Sichuan Basin and is also responsible for causing reservoir heterogeneity.

The Main Controlling Factors on the Evolution of the Cambrian Carbonate Platform in the Tarim Basin and Its Implications for the Distribution of Ultra-Deep Dolomite Reservoirs

Kehui Zhang[1]*, China University of Geosciences,Beijing (xjuer@126.com)
Xuelian YOU[2], China University of Geosciences,Beijing
Yifen Wu[3], China University of Geosciences,Beijing
Yijing Zhao[4], China University of Geosciences,Beijing
Jia Wang[5], China University of Geosciences,Beijing

Abstract

Cambrian age strata are the critical development and research stratum series of oil and gas reserves in the Tarim Basin, which contains rich oil and gas resources. The restoration of the Cambrian carbonate platform conversion and the main control factors of development has significant implication for the distribution of ultra-deep dolomite reservoirs. Based on a large number of drilling and outcrop profile data, the micro geomorphic characteristics of carbonate platforms in different periods of the Cambrian period are reconstructed in the western Tarim area, and the basin filling and structure, paleoclimate, sea level change, and seawater redox conditions are combined to analyze the main controlling factors of platform development in different periods and establish the platform evolution model. The characteristics and evolution of the Cambrian Tarim prototype basin are mainly controlled by the break-up of the Rodinia supercontinent, and its tectonic sedimentary pattern has evolved from the north–south differentiation pattern at the end of the Ediacaran to the east-west differentiation pattern of the Cambrian. The sedimentary framework of the Terreneuvian was mainly controlled by the development of paleo-uplift caused by structure and the change of seawater properties caused by the sea level variation. In the Series2 carbonate platform with extensive development, the internal differentiation is controlled by the new paleogeographic pattern of “three uplifts and two depressions”, and reef beach facies belt and platform edge begin to develop due to the lowering of sea level. Under the combined action of rapid accumulation of carbonate rocks, gradual stabilization of global sea level, and the change of ancient climate from warm and humid to hot and dry, the platform environment in the west of the Tarim Basin changed from a restricted platform environment to an evaporation platform environment, and the evaporation lagoon area in Bachu was significantly expanded in the Miaolingian. During the Furongian, the basin ended the evaporation lagoon sedimentary environment mainly due to the rise of sea level and developed a restricted platform environment again.

Abstract

In the present contribution we report new data on U-Pb detrital zircon geochronology, REE in zircon and zircon typology from the Gualanday Group located in the Upper Magdalena Valley (UMV) intermontane basin. These syntectonic deposits records the unroofing of the Colombian Central Cordillera (CC) and the erosion of paleo-highs of the emerging Eastern Cordillera (EC) in the Eocene - early Oligocene as a result of the oblique collision of the Caribbean Large Igneous Province (CLIP) against the NW margin of South America. This event started in the Late Cretaceous - Paleocene and continued propagating northeast-wards to the middle Miocene.

Clast counting was performed on ten outcrops of the conglomeratic members of the Gualanday Group (Doima and Chicoral Fm.) showcasing a major chert component among all outcrops. This can be explained by the erosion of the paleo-highs in the deforming proto-EC marine sedimentary cover. The uppermost conglomeratic member (Doima Fm.) is the only one with igneous clasts, which highlights a stronger CC provenance, related to the subjacent conglomeratic member (Chicoral Fm). U-Pb detrital zircon Geochronology performed in the samples of the finer-grained conglomerate matrix, together with zircon typology characterization of cathodoluminescence images, suggest that the Precambrian zircons are re-deposited due to their rounded shape, while the other euhedral crystals comes from nearby magmatic sources. The age spectra of sample (810005) from the northernmost Chicoral Fm. indicates late Cretaceous/ late Jurassic provenance with minor Paleozoic components. Furthermore, sample 810004, collected ~60 km southwestwards has Early Cretaceous, late Jurassic and Permian igneous sources, lacking Late Cretaceous ages although it also corresponds to the Chicoral Fm. The southernmost sample (030447) from the Doima Fm. shows mostly early Jurassic and minor components of Late Cretaceous and Permian sources. The presence of Mesozoic and Paleozoic detrital ages suggests a CC provenance of the samples. However, the prevalence of certain peaks indicates an Eocene - early Oligocene proximity of the CC magmatic source, east from the drainage divide to the ancient

locations of the samples. For instance, the northernmost sample should have been closer to the Late Cretaceous source, with a depocenter somehow isolated from the sample located ~60 km southwestwards. Similarly, the southernmost sample had a major early Jurassic source closer that did not feed any of the northern samples.

The major late Cretaceous magmatic source in the CC is the Antioquia Batholith, which is nowadays located ~190 km NNW from the sample 810005 and bounded by dextral strike-slip faults. This might imply an Eocene - late Oligocene southward location of the tectonic blocks containing this pluton, which would have sourced the northern latitudes of the UMV. A paleogeographic model is proposed considering the results of this study and other published provenance work, which highlights mostly northward displacement of tectonic blocks along the SW margin of South America triggered by the continuous propagation of the collision towards higher latitudes.

Abstract

Yinggehai Basin is a typical high temperature and high pressure basin in offshore China. In recent years, a series of large gas fields have been discovered in the shallow marine facies canyon channel and submarine fan in Dongfang district and Ledong 10 district, which demonstrate the broad prospect of deep water exploration in this basin.

A case study of normal pressure (pressure coefficient 1.05~1.20), overpressure (pressure coefficient 1.37~2.02) and thermal overpressure reservoir (pressure coefficient 1.74~2.30) of the Miocene Huangliu Formation in Ledong 10 area of Yinggehai Basin was conducted, impact of different pressure backgrounds and thermal fluid activities on reservoir diagenesis, pore evolution and reservoir quality are analyzed, based on identification of cast thin sections under microscope, scanning electron microscope, measurement of image pore throat, capillary pressure, porosity and permeability, inclusion homogenization temperature and analysis of XRD of clay minerals, combined with burial thermal evolution history. The research result shows that the normal pressure reservoir of Huangliu Formation is characterized by strong compaction and cementation, and weak dissolution, average pore loss by compaction and cementation is 22.8% and 9.5%, respectively, average pore increment by dissolution is 4.6%, resulted in the initial porosity of 34.9% to the present 7.2%. Affected mainly by overpressure and hydrocarbon fluids, the overpressure reservoir is of relatively weak compaction, weak dissolution and strong cementation, and experienced three stages of pore evolution. Average pore loss by compaction and cementation is 21.5% and 16.8%, respectively, and average pore increase by dissolution is 6.8%resulted in the initial porosity of 38.8% to the present 7.6%. The diagenetic stage reaches substage A2 of mesodiagenesis.

Deep-seated thermal fluid activity in the study area is dominated by CO2 with a small amount of H2S, mainly influenced the middle and lower parts below 3500m~3900m. Affected both by overpressure and thermal fluid, thermal overpressure reservoir is characterized by accelerated transformation rate of authigenic clay minerals, vitrinite reflectance mutation, reduced formation water salinity, the higher homogenization temperature of inclusions than the normal formation maximum temperature, and with development of hydrothermal mineral assemblage. This kind of reservoir is of relatively strong compaction, strong dissolution and weak cementation, and

experienced pore evolution of four stages. The diagenetic stage of the thermal overpressure reservoir reaches stage B of mesodiagenesis. Average pore loss by compaction and cementation is 23.0% and 13.8%, respectively, and average pore increment by dissolution is 7.7%resulted in the initial porosity of 38.1% to the present 9.2%. The diagenetic stage reaches substage B of mesodiagenesis.

Overpressure and thermal fluid activity have important effects on diagenetic pore evolution and favorable reservoir formation. High-quality reservoirs in the study area tend to develop in the thermal overpressure reservoir of the gravity channel and submarine fan sand body in the middle and lower part of Huangliu Formation.

Origin of dolomite in the Middle Permian Maokou Formation in eastern Sichuan Basin under the coupling constraints of hydrothermal and karstification

Ling ZHOU[1]*, China University of Petroleum (East China) (jolene20@163.com)
Guangwei Wang[2], China University of Petroleum (East China)
Fang Hao[3], China University of Petroleum (East China)

Abstract

Dolomite reservoirs are significant for deep oil and gas, but the controversial origin of the Maokou dolomite under the complex geological setting restricts hydrocarbon exploration. It is difficult to identify the genesis of dolomite when the reservoir was subjected to multiple diagenetic or tectonic events. This study investigated the middle Permian Maokou Formation of the eastern Sichuan Basin, southwestern China, which has giant natural gas reserves. Petrological and geochemical analyses (e.g., trace elements, δ13C, δ18O, 87Sr/86Sr, and U-Pb dating) were performed on various carbonates to clarify the types of dolomites and their origin of the Maokou dolomites. In addition, combined with the special geological setting in this area affected by karstification and hydrothermal action, the source of dolomitizing fluids, dolomitization time, and the main controlling factors of dolomite distribution were clarified.

Five types of dolomites were found in the Mbr2 of the Maokou Formation in eastern Sichuan Basin, including micrite-crystalline dolomite (Dol-1), fine-crystalline dolomite (Dol-2), medium-crystalline dolomite (Dol-3), medium-coarse crystalline dolomite (Dol-4), and saddle dolomite (Dol-5). The dolomitizing fluids of Dol-1, Dol-2, Dol-3, and Dol-4 types derived from the seawater-like fluids. The Dol-5 type of cement in the fractures and vugs has obvious Eu anomaly, and is mostly associated with quartz and other hydrothermal minerals, indicating that it is hydrothermal-related cements. Dol-2 type is the most common type of dolomite in the study area, with red cathodoluminescence (CL). Dol-1 and Dol-2 types were formed in the dolomitization of seawater restricted by shoal bridges during the penecontemporaneous period. Dol-2 dolomite has lower δ18O values, and higher Mn/Sr ratios than that of Dol-1 dolomite, indicating the recrystallization of dolomite influenced by emeishan large igneous province. Dol-3 type was formed by metasomatism of the silicon-rich fluids replacing parts of dolomites. High ΣREE concentrations and high Mn but low Fe concentrations of Dol-4 type of cements suggest their karstification-related origin.

Dolostones stably distribute along the platform edge and are mainly controlled by sedimentary facies. The dolomitization occurred at the penecontemporaneous stage near the surface or shallow burial stage with ages of 263.1±9.5 Ma and 263.5±18.3 Ma, which is the earliest. Later, the silicon-rich fluids leached from the extrusive basalts by meteoric water replaced parts of dolomites along the contemporaneous faults. Then, the Maokou Formation suffered from widespread karstification at the end of the deposition, resulting in a large number of karst dissolution fractures and vugs, and the precipitation of some Dol-4 types with ages of 259.9±3.9 Ma and 260.5±2.8

Ma, which is consistent with the large-scale karstification at the end of the Maokou Formation. Finally, deep hydrothermal fluids migrated upward through the faults, leading to extended corrosion along the dominant karstification-related fractures and vugs, but also accompanied by the cementation of abundant Dol-5 types, blocky calcite, and quartz cements. The contribution of the tectonic-hydrothermal fluids to the reservoir space is not significant.

Controlling factors of tight sandstone reservoirs: A case study of the He 8 reservoir in the Ordos Basin

gaixia xia CUI[1]*, School of Geosciences and Technology, China University of Petroleum (East China) (gaiixiacui95@163.com)
shou yu XU[2], 15253292259
Qin lian Wei[3], 15891449010

Abstract

Tight sandstone gas reservoirs, as a representative of unconventional gas reservoirs, possess significant reserves and abundant oil and gas resources. Consequently, they have become a crucial focus for governments and enterprises in terms of exploration and development. In the Longdong area located in the southwest of the Ordos Basin, a relatively complete set of dense, thick sandstones with multiple layers rich in oil and gas has been continuously deposited due to the sedimentary environment and structural factors. As exploration into tight sandstone oil and gas wells deepens, this area is gradually emerging as a new development replacement zone. This research area conducted experiments such as casting thin sections, scanning electron microscopy, high-pressure mercury injection tests, physical property analysis, etc., to study parameters including reservoir properties, lithology characteristics, and pore structure features. The results revealed that lithic quartz sandstone (61.6%) and lithic sandstone (15.06%) were the main rock types in the He 8 reservoir. The overall grain size was coarse with medium sorting, while intragranular dissolution pores dominated, followed by intergranular pores or crystallographic micro-pores. The thickness range of the storage layer exhibited significant variation along with strong heterogeneity in rock type distribution within it. Reservoir properties are jointly controlled by sedimentary facies and diagenesis processes, where sedimentary facies fundamentally determine reservoir property conditions. Sand body structure plays an important role in reservoir properties, where cutting-type single-sand-body storage exhibits better physical properties than spliced-sand-body storage, while isolated single-sand-body storage is inferior to both. Compaction is the primary reason for densification, whereby water mica serves as the primary factor causing cementation-induced densification, while low-degree dissolution has a limited effect on improving reservoir quality.

Sedimentary Dynamics and Paleoenvironmental Signatures in the Witbank Coalfield, Main Karoo Basin of South Africa

Lindani Ncube[1]*, UNISA (lindyncube@yahoo.co.uk)
Sonwabile Kidwell Rasmeni[2], UNISA

Abstract

Situated in the northern sector of the Main Karoo Basin, the Witbank Coalfield displays a basin-like configuration extending from Brakpan in the West to Belfast in the East. The northern boundary interfaces with pre-Karoo basement rocks, mainly Waterberg sandstones, while the southern boundary highlights the notable pre-Karoo basement ridge known as the "Smithfield ridge." This basin formed in a shallow cratonic paralic environment, experiencing gradual subsidence during the late Carboniferous to early Permian period. The Main Karoo Basin is recognized as an asymmetric retro arc foreland, abundant in petroleum, originating from the Paleozoic to Early Mesozoic subduction of the Paleo-Pacific Plate beneath the Gondwana Plate. Sedimentary lithologies within the basin, part of the Karoo Supergroup, consist of sandstone sequences reflecting diverse depositional environments, including glacial, deep marine, fluviolacustrine, and aeolian settings. Our study focused on the sediments of the early to late Permian Vryheid Formation in the Ecca Group, a component of the Karoo Supergroup. Employing petrographic methods, we aimed to comprehend the factors influencing Permian sandstone reservoir quality to enhance predictions of porosity and permeability. Contemporary reservoir quality predictions now consider primary sediment supply, depositional environment, detrital bioclast fraction, and the influx of organically derived carbon dioxide. The Vryheid Formation's sedimentary profile comprises primarily arkose and sub-arkosic sandstone lithology. Early diagenesis processes, involving both mechanical and chemical compaction, were identified as pivotal in controlling porosity loss, indicating an incremental increase in compaction strength with burial depth. This is evident in the evolving grain contact manners, transitioning from point contact to long plane contact, concave-convex types, and sutured contacts among neighboring framework grains. Clay minerals like kaolinite, illite, and smectite act as cements or replacement minerals, particularly replacing feldspars. These clays form during early diagenesis, replacing quartz and feldspar through secondary replacement. Some sediments exhibit fine quartz cement and quartz overgrowths, indicating variable current strengths during sedimentation. Silica is locally supplied by pressure solution, dissolution of siliceous minerals, or siliceous skeleton grains. Additionally, silica may be imported from other areas of the basin during episodes of fluid flow related to deep basin mineral dehydration or tectonic activity. The Witbank Coalfield's depositional environment reflects marine influences, especially near the Dwyka continental glaciation, evidenced by marine indicators like tadpole-shaped pyrite. The unique paleoenvironmental context is supported by the nature of source rocks, predominantly granite with high proportions of alkali feldspar. The vertical succession in the Witbank Coalfield unveils stratigraphic complexity, featuring early diagenetic processes such as albitization, feldspar

dissolution, and kaolinite infill. Tectonic processes, including subsidence, faulting, and folding, have played a crucial role in shaping the basin's geometry.

Miruo LIN[4], Key Laboratory of Deep Oil and Gas, China University of Petroleum (East China)

Abstract

Diagenesis plays a crucial role in shale oil reservoir formation. However, complex organic-inorganic interactions result in pore system formation and heterogeneity changes at the centimeter, or even micrometer scale, which controls the evolution of shale oil reservoirs. In this paper, an integrated approach including core observation, thin section observation, cathodoluminescence thin section observation, scanning electron microscope, μ-XRF analysis, electron microprobe analysis, AMICS analysis, LA-ICP-MS analysis, and isotope analysis was used to clarify the laminae combination carbonate-rich shale, diagenetic alterations in different types of shale laminae and the controls on shale oil reservoir formation. According to the lamina combination, the carbonate-rich shale in the Permian Lucaogou Formation can be divided into three types. They are shale consists of dolomitic lamina and terrigenous felsic lamina (Type A shale), shale consists of calcite-rich tufaceous lamina and terrigenous felsic lamina (Type B shale) and shale consists of calcareous lamina and tufaceous lamina (Type C shale). Dolomite cementation is the major diagenesis in terrigenous felsic lamina of Type A shale. The dolomite can be identified as the early stage forming from recrystallization of micrite dolomite, and the late stage precipitate from adjacent dolomitic lamina. In the terrigenous felsic lamina of Type B shale, however, the calcite cementation is the dominated diagenesis, which was sourced from adjacent calcite-rich tufaceous lamina. Also, some feldspar dissolutions occurred in terrigenous felsic lamina during organic matter evolution. For the Type C shale, the main diagenetic alteration is micrite calcite recrystallization in calcareous lamina. The dissolution and precipitation of carbonate minerals between different laminae of carbonate-rich shale reveal that the organic matter evolution significantly influence the diagenetic alterations of inorganic minerals. Particularly, the diagenetic mass transfer and redistribution at the micro-scale in a relatively diagenetic system were confirmed by organic-inorganic interactions in laminated shale. In this process, dissolution pores and recrystallization pores have provided considerable reservoir pores for shale oil.

Different Sedimentation, tectonism, diagenesis of ultra-deep tight sandstone reservoirs and its relationship with reservoir quality: a case study of Dabei Gas field in Kuqa Depression, Tarim Basin

Xiaotong XU[1]*, China University of Petroleum(Beijing) (1473078717@qq.com)
Lianbo Zeng[2], China University of Petroleum(Beijing)

Abstract

Sedimentation is the basis for the development of high-quality reservoir, and tectonism, diagenesis are the key to reforming reservoir quality. Ultra-deep tight sandstone reservoir exhibits extremely low matrix porosity and permeability, strong and complex diagenesis, fracture development, and strong heterogeneity. Under the background of overall densification, reservoirs with relatively good physical properties often develop. In order to understand control factors of reservoir quality and distribution law of high-quality reservoirs, this study focuses on the Lower Cretaceous Bashijiqike Formation in Dabei gas field, Kuqa Depression, Tarim Basin. Using cores, well logging, thin sections, scanning electron microscopy, cathodoluminescence, X-ray diffraction and physical properties, characteristics of petrology, diagenesis and fracture were studied. Then, effects of tectonism and diagenesis on different petrofacies were discussed. Finally, relationships between fracture, petrofacies and sedimentary microfacies were established. Sandstones are mainly lithic arkose. Authigenic minerals mainly include carbonates, anhydrite, authigenic clays, siliceous and albite. Natural fractures are mainly high angle and vertical shear fractures and are mainly filled with carbonates. The matrix is generally characterized by extremely low porosity and permeability and exhibits strong heterogeneity. Natural fractures can enhance matrix permeability by several orders of magnitude. Based on petrological fabric and degree of tectonism and diagenesis, sandstones are divided into ductile-rich sandstone, carbonate-cement sandstone and ductile-lean sandstone. Ductile-rich sandstone is characterized by strong compaction, weak cementation, weak dissolution. Carbonate-cement sandstone exhibits strong cementation, weak compaction, weak dissolution. Both are densification in early diagenetic stage. However, compaction and cementation are two main factors that control the brittleness of sandstones. Under the same differential stress, sandstones with high brittleness are susceptible to fracture. Therefore, ductile-rich sandstone and carbonate-cement sandstone are prone to fracture development, which greatly increases their permeability and becomes effective seepage channels. Ductile-lean sandstone is characterized by medium compaction, weak to medium cementation, strong dissolution. For low degree of compaction and cementation in early diagenesis stage, ductile-lean sandstone can not only preserve primary pores, but also be transformed by acidic fluids in late diagenesis stage. Distribution of different petrofacies is generally controlled by sedimentary microfacies. Ductile-lean sandstone with best physical properties is mainly distributed in the middle-lower part of distributary channel or the middle-upper part of mouth bar. This distribution law will provide guidance for the exploration of ultra-deep high-quality reservoirs.

Differential precipitation mechanism and their effects on the reservoir quality of alkaline diagenetic environment in the tight Middle Jurassic sandstone in the Central Sichuan Basin, SW China

DONG PING TAN[1]*, Tan Dongping (1316212122@qq.com)
YING CHANG CAO[2], 13505325516
JIAN WANG[3], 18366201873

Abstract

The strong heterogeneity of continental tight sandstone reservoir was mainly determined by various types and strength of different cementation during burial process. However, Precipitation mechanism and its impact on reservoir quality of differential cement combination are rarely well understood. The Middle Jurassic Shaximiao Formation is one of the most important tight sandstone gas reservoirs in the Central Sichuan Basin, China. The reservoir heterogeneity of Shaximiao Formation sandstone, which was caused by the differential cement combination, is crucial to reservoir prediction in the Central Sichuan Basin. The diagenesis of these tight sandstones was examined using a variety of petrographic and geochemical techniques, including thin section description, X-ray diffraction (XRD), scanning electron microscopy (SEM), Cathodoluminescence (CL) imaging, electron probe analysis, fluid inclusions and isotopic analysis. Diagenetic minerals in the Shaximiao Formation (J2s) sandstone comprise calcite, laumontite, chlorite and dissolution. The pore space of J2s sandstone mainly comprises primary pores and secondary pores formed after mineral dissolution. The reservoir sandstones can be divided into six types according to different combinations of the laumontite, chlorite and calcite. Authigenic chlorite coating of J2s sandstones occurred via chloritization of smectite during eodiagenesis. Laumontite cements derived from transformation of volcanic rock fragments, were precipitated in a strong alkaline environment with high pH value (9.5–12) and abundant Ca2+, Si4+, Al3+ during eodiagenesis. The δ13C and δ18O isotopic values and petrological characteristics indicate that calcite cement was related to feldspar dissolution and decarboxylation of organic matter. The different cement combinations were determined mainly by the sedimentary facies and subsequent diagenetic environment evolution. Laumontite precipitation needs a stronger alkaline diagenetic environment than that for chlorite and calcite. The early chlorite coating provided sufficient remaining pore-space for pore-filling laumontite and calcite precipitation. The presence of pore-filling laumontite decreased space for calcite precipitation. However, laumontite is more readily soluble than calcite. The different cement combinations have distinct residual pore space combinations meaning that some intervals of rock have sufficient permeability to act as viable reservoir rock whilst other combinations do not.

The coupling relationship between sandstone reservoir densification time and hydrocarbon charging time: A case study of the Yanchang Formation in South Ordos Basin, China

Zhen Wang[1]*, China University of Petroleum, Beijing (wangz_0205@163.com)
LIANBO ZENG[2], China University of Petroleum, Beijing
HONGHAN CHEN[3], China University of Geosciences, Wuhan

Abstract

As the second largest sedimentary basin in China, the Ordos Basin is rich in oil and gas resources. Conventional and unconventional tight oil reservoirs have been developed together, among which the Yanchang Formation of Mesozoic is rich in tight oil resources and has great exploration potential. However, the genesis of tight reservoirs in the Yanchang Formation in the Ordos Basin and its relationship with hydrocarbon charging remains controversial. Taking Chang 8 Members of Yanchang Formation in the south of Ordos Basin as the research object, this study investigated the reservoir diagenesis and accumulation process in the study area, to clarify the cause of reservoir densification and its relationship with the sequence of hydrocarbon charge events in this area. The reservoir diagenetic sequences were established by observing the thin sections with transmitted light, fluorescence, cathodoluminescence and stable oxygen and carbon isotope analysis. It is considered that compaction and carbonate cementation are the main reasons for the densification, porosity and permeability decline of the reservoir. By combing the relationship between reservoir porosity, calcite cement content, and buried depth, it is concluded that when calcite cement content is less than or equal to 7%, sandstone reservoir densification follows the rule of compaction. When the content of calcite cement is greater than 7%, it is considered that the reservoir densification follows the rule of cementation densification. However, due to the lack of valid dating methods, it is impossible to accurately obtain the compaction time. In this study, the coupling relationship between cementation densification time and hydrocarbon charging is mainly discussed. In the context of diagenetic sequences, the reservoir densification history was characterized by oxygen isotope calculation temperature-burial history projection method, laser in-situ U-Pb dating, and porosity evolution curve. The hydrocarbon charging history in the study area was established by using fluid inclusions and microscopic fluorescence spectrum combined with one-dimensional basin modelling. Finally, the Diagenesis-Accumulation-Pore evolution model is established for the Chang 8 Yanchang Formation in the Ordos Basin. The results show that the densification time of calcite cement determined by various methods is 167.4~118.3Ma. Three hydrocarbon charge events occurred in the study area, the first charge event occurred in the early of Early Cretaceous (136.1~124.0 Ma), the second charge event occurred in the middle of Early Cretaceous (121.1~114.0 Ma), and the third charge event occurred in the late of Early Cretaceous (111.8~95.9 Ma), among which the second and third stages are the main accumulation periods. In summary, the reservoir densification in the study area occurred from 167.4 to 118.3 Ma, oil charging began at 136.1 Ma, and the peak time of oil charging began at 121.1 Ma. The

results exhibit the reservoir densification before oil charging, with charging continuing after densification. It reveals, therefore, the coupling relationship between reservoir densification and hydrocarbon charging events, which has important implications for tight reservoir evaluation in the Ordos Basin.

Mineral dissolution-precipitation mechanism in ultra-deep clastic rock reservoirs: a case study under the temperature and pressure background of Bashijiqike Formation of Kuqa Depression, Tarim Basin, China

Bing WU[1]*, School of Geosciences, China University of Petroleum (East China)
(b21010048@s.upc.edu.cn)
Jian Wang[2], National Key Laboratory of Deep Oil and Gas
Yingchang Cao[3], National Key Laboratory of Deep Oil and Gas

Abstract

Deep ultra-deep reservoirs, as an important succeed field for future oil and gas resources, have very significant value of research, with 60% of recoverable reserves distributed in clastic rock reservoirs. The clastic rock reservoirs of the Bashjiqike Formation, developed in the Kuqa foreland basin, have experienced both gradually increasing formation temperature and pressure conditions and strong lateral compressive stress during geological history. Under such complex geological conditions, the dissolution-precipitation response of minerals has a significant impact on the quality of reservoir development. We studied the dissolution-precipitation reaction characteristics of quartz (Q2 type surface) under deep formation temperature, pressure, and lateral compressive stress conditions through molecular dynamics simulation experiments. The research results indicate that in alkaline fluid environments, compared to stressed-free condition, silica dissolved under compressive stress conditions can diffuse further in the solution, and after reaction, the amorphous layer formed on the surface of quartz is thicker. Within the amorphous layer, there are multiple quartz species, namely Q3, Q2, Q1, Q0, indicating the existence of a transition zone in the fluid mineral reaction process. It can be called an alteration layer or a transition layer. This layer is at the forefront of mineral dissolution reactions. In the simulated diagenetic environment, the dissolved silica ultimately undergoes re precipitation within the transformation layer. Our research indicates that on the one hand, compressive stress conditions promote the dissolution of quartz, and on the other hand, it indicates that the dissolution-precipitation reaction of quartz occurs within the alteration layer on its surface. The dissolution-precipitation reaction of minerals in deep formation has a significant impact on reservoir quality, and an open diagenetic environment is more conducive to the migration of dissolved substances.

Diagenesis and reservoir quality prediction of Jurassic sandstones, central Junggar Basin, NW China

Penghui ZHANG[1]*, Hohai University (zph010@163.com)
Yong Il LEE[2], Seoul National University

Abstract

Recent hydrocarbon exploration realm has been expanded to deep tight oil and gas from the Lower Jurassic sandstone reservoirs in the central Junggar Basin, NW China. These deeply-buried sandstones are overall overpressured with hydrocarbon saturated or bearing, yet they have not been intensively investigated in terms of diagenesis and reservoir quality prediction. The Lower Jurassic sandstones primarily comprise feldspathic litharenites deposited in lacustrine-deltaic environments under warm, humid climatic conditions in a high-paleolatitude continental basin. Progressive burial, with minimal strata uplift, maintained a relatively stable burial-thermal regime, resulting in minor variations in diagenetic modifications such as compaction, cementation by carbonates, quartz and clay minerals, as well as partial dissolution of feldspars and rock fragments. Despite generally similar diagenetic histories, these tight sandstones exhibit considerable variations in pore system development, leading to heterogeneous reservoir quality. Porosity reduction was primarily due to the effect of compaction. In contrast, the development of overpressure, which occurred from the Early Cretaceous onwards, has been recognized to limit extensive chemical compaction and quartz cementation, and it would in turn potentially lead to porosity preservation. Additionally, the partial dissolution can generate secondary porosity as a non-negligible factor associated with porosity maintenance and is more likely concentrated in coarser-grained sandstone intervals. These findings suggest that an integrated consideration of the roles of depositional settings and diagenesis, when linked to burial-thermal history and overpressure evolution conditions, is essential for predicting reservoir quality.

The Characteristics and Genetic Mechanisms of the Lower Paleozoic Carbonate Reservoirs in South Yellow Sea Basin

Yu ZHENG[1]*, Research Institute of Bohai Oil Field, CNOOC (zhengyu3@cnooc.com.cn)
Bo Yang[2], Research Institute of Bohai Oil Field, CNOOC
Rucai Zhang[3], Research Institute of Bohai Oil Field, CNOOC
Zhen Huang[4], Research Institute of Bohai Oil Field, CNOOC
Xilong Gao[5], Research Institute of Bohai Oil Field, CNOOC

Abstract

Seismic data and drilling data show that carbonate reservoirs are developed in the Lower Paleozoic of the central uplift of the South Yellow Sea Basin. However, the reservoir genesis mechanism is unclear. In order to clarify the reservoir of oil and gas in this area, this study focuses on the reservoir characteristics and genesis.

The results of rock thin section and physical property analysis show that the carbonate reservoirs in the study area are mainly ultra-low pore and ultra-low permeability reservoirs.Among them, the limestone reservoir is mainly fracture type reservoir, and the dolomite reservoir is fracture-pore type reservoir with more developed dissolution pores and intercrystalline pores.On the whole, the physical properties of dolomite reservoirs are better than limestone, and some dolomite reservoirs can reach the II class reservoir evaluation standard.Sedimentary facies analysis shows that the limestone is mainly formed in the open platform sedimentary environment, and the sparry calcite cement is mainly formed between particles, which is the reason why the limestone reservoir is more dense.The dolomite is mainly formed in the evaporation platform sedimentary environment, and some dolomite is formed in the burial stage.The pore formation mechanism of evaporation dolomite is that the fine dolomite crystals form the pore framework, and the gypsum, high magnesium calcite and other soluble minerals formed in the early stage of the pores form mold pores after dissolution.The buried crystal dolomite pore space is mainly residual dissolution pores and intercrystalline pores, and the rapid filling of siliceous material destroys the pore space. The geochemical elements and inclusion analysis show that the siliceous filling mainly occurs in the late diagenetic stage. The homogenization temperature of the inclusions indicates that the formation temperature of the siliceous between the silica dolomite grains is low, and the source of the siliceous is mainly the rapid precipitation of the SiO2 in the formation fluid due to the decrease of the solubility.In addition, the atmospheric freshwater in the supergene stage plays a constructive role in the reconstruction of the reservoir, forming a large number of dissolution pores, and the carbon and oxygen isotope value is low and negative.

In summary, dolomite reservoirs are the main reservoirs in the study area. The uplift of the Indosinian tectonics makes the solubility of the SiO2 in the fluid of the dolomite formation decrease, and the rapid precipitation occurs in the pores, forming a large number of siliceous filling, making the pore space smaller. On the other hand, the dissolution of freshwater plays a constructive role in the reconstruction of the reservoir, forming a large number of dissolution pores, and expanding the pore space of the dolomite.

Origin of the carbonate cements in the upper Miocene Huangliu Formation in the Ledong Area, Yinggehai Basin, China

xuezhe LI[1]*, 18243502522 (1617568389@qq.com)
Yanzhong Wang[2], 18253266698
Fang Hao[3], 17685561729
Jinqiang Tian[4], 18953282068

Abstract

Carbonate cements are significant cause of porosity and permeability reduction in the clastic rock reseroirs in the Upper Miocene Huangliu Formation in the Ledong Area, Yinggehai Basin, China. We apply petrological, mineralogical and geochemical methods, combined with tectonic evolution, burial history and thermal history to elucidate different carbonate cements origin. The results show that the carbonate cements in the reservoirs of Huangliu Formation in Ledong Area originate from hydrothermal fluids and carbonate minerals of source rocks. And the diapir of Ledong area provides a transportation to the reservoirs, the rock composition of reservoirs makes the difference. In poorly sorted coarse clastic rocks such as coarse sandstone and pebbly sandstone, the reservoir is strongly cemented by calcite, with bright and dark calcite under cathodoluminescence. The carbon isotope of the bright calcite ranges from 2.45‰ to 4.8‰, the oxygen isotope ranges from -7.05‰ to -6.85‰, the fluid inclusions homogeneous temperatures ranges from 154.9 ℃ to 157.9 ℃, and 87Sr/86Sr ranges from 0.70881 to 0.70914. The carbon isotope of dark calcite ranges from 3.15‰ to 4.35‰, oxygen isotope ranges from -6.93‰ to -6.57‰, 87Sr/86Sr ranges from 0.70888 to 0.70912, and the fluid inclusions homogeneous temperature ranges from 139.5 ℃ to 148.1 ℃. Moreover, the two-phase calcite cements have LREE-rich patterns. And the Yb/Ca-Yb/La scatterplot shows two-phase calcite cements originate from hydrothermal fluids. From 9 Ma to 7.8 Ma before present, with the diapiric activity in Ledong Area, the hydrothermal fluid rich in carbon dioxide was formed by pyrolysis of carbonate minerals in the deep strata, mixed with some carbon dioxide from organic acid decarboxylation of source rocks of Meishan Formation and Sanya Formation migrate to reservoirs. The dark and bright calcite cements were successively precipitated in the coarse-clastic reservoirs. In well-sorted fine clastic rocks such as fine sandstone and medium sandstone, the reservoir is porous and develops dark calcite cements under cathodoluminescence and some ferroan calcite. The carbon isotope of dark calcite ranges from -1.71‰ to -0.37‰, the oxygen isotope ranges from -12.2‰ to -8.05‰, the 87Sr/86Sr ranges from 0.70902 to 0.70912, and the fluid inclusions homogeneous temperatures ranges from 151.8 to 169.7 ℃. The dark calcite cements have LREE-rich patterns. And the Yb/Ca-Yb/La scatterplot shows dark calcite cements originate from hydrothermal fluids. From 1.5 Ma to the present, with the reactivation of the diapir of Ledong Area, and the inorganic carbon dioxide produced by the decomposition of inorganic carbonate minerals in the source rocks of Meishan Formation and Sanya Formation was transported along the diapir to the reservoirs, and the dark calcite cements under cathodoluminescence precipitated in the fine-clastic reservoirs.

Evidence of deep fluid activity in Jurassic tight sandstone reservoirs in the Northern Kuqa Depression

Yifan Zhang[1]*, China University of Petroleum (East China) (zhangyf0215@outlook.com)
Kelai Xi[2], China University of Petroleum (East China)
Yingchang Cao[3], China University of Petroleum (East China)

Abstract

Understanding diagenetic fluid types and their effects on diagenesis is important to identify the main control factors of reservoir characteristics and predict reservoir sweet spots. Reservoir space destruction caused by strong cementation, especially quartz overgrowth and calcite, is notable in the Lower Jurassic Ahe Formation (J1a) sandstones near the deep-rooted fault (Yiqikelike Fault) in the Kuqa depression. Different authigenic minerals and widely varying cementation contents indicate the complexity of diagenetic fluids. Therefore, we investigated strong cementation using petrographic and geochemical methods, including cathodoluminescence, scanning electron microscopy, laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS), and stable isotope analysis. The authigenic quartz cements were mainly in the form of quartz overgrowth, where its outer edge had a regular shape with thickness, and its color was non-luminescent under CL. The calcite was mainly cemented in the primary pores after quartz overgrowth cementation, which mainly exhibited dark orange luminescence under CL. The contents of authigenic quartz and calcite increased as they approached the deep-rooted fault, with maximum concentration of quartz and calcite of up to 8.73% and 8.92%, respectively. Abnormally high homogenization temperatures of the fluid inclusions were observed in the quartz overgrowth, one of which reached 156 ◦C. In calcite, the rare earth element Eu exhibited abnormal characteristics, and the carbon isotopes ranged from -8.00‰ to -2.00‰. Therefore, it is likely that deep fluids are involved in reservoir diagenesis near a deep-rooted fault. This study provides a good example of diagenetic evolution in deep sandstone reservoirs and the negative effects of the involvement of deep fluids in diagenetic processes.

Diagenesis and Evolution of lacustrine carbonate reservoir in the Upper part of the Fourth Member of the Shahejie Formation in the Gentle Slope Belt of the Bonan Sub-sag, Jiyang Sub-basin

Jie Yu DU [1]*, 15192559010 (1464639543@qq.com)
Zhong Yan Wang[2], 18253266698
Chang Ying Cao[3], 17685561715
Yuan Kai Yu[4], 18243502469
Ping Shu Wang[5], 18366236887

Abstract

Diagenesis is significant to the research on oil and gas reservoirs. The lacustrine carbonate reservoir in the Upper Part of the Fourth Member of the Paleogene Shahejie Formation (Es4s) in the gentle slope belt of the Bonan Sub-sag in Jiyang Sub-basin has diverse rock types and reservoir spaces, which is one of the most important targets for oil and gas exploration. However, the complex diagenetic types and unclear diagenetic evolution have led to the strong heterogeneity in reservoir and so hard to predict the high-quality reservoir. Comprehensive analysis methods such as the observation of cores and thin sections, LA-ICP-MS, C-O isotope, homogeneous temperature of fluid inclusions were systematically used to investigate the diagenesis and diagenetic evolution of the lacustrine carbonate reservoir in the Es4s. The study area primarily developed granular dolomite, calcarenite, bioclastic limestone and argillaceous limestone. The particles were round to sub-round and the contact relationship between the particles was mainly point-line contact. The storage space were dominated by residual primary intergranular pores and a few intragranular dissolution pores. According to the differences in color under the cathodoluminescence (CL), three kinds of cements could be recognized: earthy yellow calcite cement, dark calcite cement and bright calcite cement, among which the bright one is less found. The earthy yellow calcite cement has obvious "abundant MREE" hat-shaped distribution characteristic and is mainly found in the dolarenite dolomite and algal bonded dolomite with darker color under plane-polarized light. At the same time two kinds of dolomite and the earthy yellow calcite cement have similar C positive feature, so the diagenetic fluid of earthy yellow one may be syn-depositional intergranular water. The C isotope of the dark calcite cement ranges from -0.41‰ to 1.88‰ and the value of bright one is -0.22‰, respectively, having obvious negative C compared with the earthy yellow calcite ranging from 0.28‰ to 2.77‰, indicating the source of C may be complicated and different. Meanwhile, considering the flat REE distribution patterns of two

cements, it's believed that the diagenetic fluid of dark and bright calcite cement is related to the mixture of organic acid and formation water. The positive Eu anomalies with Eu values of 1.32-1.88 *and all* $\delta^{18}O$ *datas range from* -13.98‰ *to* -17.07‰(*obviously small than* -10‰) *of the three stage calcite cements further indicate the influence of hydrothermal fluid. Combined with petrography, microscopic and geochemical characteristics of minerals developed in different diagenetic stages, it's suggested that the diagenetic evolution sequence of lacustrine carbonate reservoir in the* Es_4^s *in the gentle slope belt of the Bonan Sub-sag is as follows: early compaction and pressure dissolution → syngenetic-penecontemporaneous dissolution of particles → earthy yellow calcite cementation → dark calcite cementation → bright calcite cementation.*

Origin Mechanism and Favorable Area Prediction of Scale-Type High-Quality Carbonate Reservoirs in the South Yellow Sea Marine Basin, China

Bo YANG[1], CNOOC China Limited,Tianjin Branch
Ying GUO[2]*, CNOOC China Limited,Tianjin Branch (350426124@qq.com)
Xilong GAO[3], CNOOC China Limited,Tianjin Branch
Yu ZHENG[4], CNOOC China Limited,Tianjin Branch
Xiaoling WANG[5], CNOOC China Limited,Tianjin Branch

Abstract

The exploration potential of the Paleozoic marine basin in the South Yellow Sea is enormous, but the origin mechanism of its carbonate reservoirs is complex, and the controlling factors are not yet clear, severely restricting the progress of oil and gas exploration in the region. In this study, based on drilling, field outcrop, petrological, rock geochemical, and seismic data, the origin mechanism of high-quality carbonate reservoirs in the study area was investigated. The results indicate: 1) Ancient climate and environment are the fundamental factors controlling the development of dominant lithology and lithofacies differentiation in the study area. From the late Sinian to the Cambrian, high ancient temperatures and salinity gradually decreased, controlling the development of early-stage dolomite in the Upper Sinian and Lower Cambrian. Additionally, due to higher ancient temperatures in the study area compared to the Upper Yangtze region, conducive to the abundant growth of algae, large-scale reef-flat facies reservoirs developed in both the Upper Sinian and Lower Cambrian, differing significantly from the Lower Cambrian grainy shoal facies reservoirs in the Upper Yangtze region. 2) Ancient sea level fluctuations are the basic conditions controlling the development of multi-level karst reservoirs. Multiple periods and levels of ancient erosion surfaces developed in the Paleozoic in the study area, serving as strong karstification zones. Moreover, a regional-scale regression occurred in the upper part of the Lower Cambrian, providing potential for the development of intra-fracture karst reservoirs. 3) Ancient tectonic activity is a key factor in forming late-stage high-angle effective fractures, thereby improving reservoir quality. Controlled by multiple tectonic movements, four stages of structural fractures developed in the carbonate reservoirs in the study area. Late-stage high-angle fractures formed under extensional stress during the Mid-Late Yanshan and Xishan periods are effective fractures, concentrated in extensional normal fault zones, playing a dominant role in reservoir improvement. Based on the above studies, it is pointed out that the southeastern part of the central uplift and the overlap area of developed extensional faults are favorable areas for high-quality reservoirs.

Characteristics and origin of multistage chlorites in tight sandstone reservoirs of the Upper Jurassic Qigu Formation in Yongjin Area, Junggar Basin, China

Xinyuan HUANG[1]*, China University of Petroleum(East China) (2898306796@qq.com)
Yanzhong Wang[2], China University of Petroleum(East China)
Yingchang Cao[3], China University of Petroleum(East China)
Kai Sheng[4], China University of Petroleum(East China)

Abstract

Chlorite plays a crucial role in petroleum development, and is widely developed in tight sandstone reservoirs of the braided river delta front of the Upper Jurassic Qigu Formation in Yongjin Area, Junggar Basin, China. The chlorite has been analyzed using an integrated approach of petrographic observations and geochemical analyses to systematically study its type, distribution and origin in the study area. Three types of chlorites are developed in the study area: recrystallized chlorite, autogenic chlorite and grain replacive chlorite. Recrystallized chlorite is transformed from the precursor berthierine clay and maintains the characteristics of the precursor clay. It grows in the form of adherent petals parallel to the particle surface. The distribution of recrystallized chlorite is controlled by sediment transport and deposition processes. Following early compaction, alteration of abundant intermediate-basic volcanic rock fragments provided Fe2+ and Mg2+ for chlorite recrystallization. In areas with poorer sandstone sorting, there is a higher concentration of volcaniclastic debris, leading to increased development of recrystallized chlorite. In recrystallized chlorite, Fe=3.73-6.83, Mg=0.97-2.04 (based on 28 oxygen atoms). In comparison, authigenic chlorite has higher Fe and Mg (Fe=6-7.53, Mg=1.21-2.41). Authigenic chlorite is in the form of disorganized flakes with large, well-developed crystals and is often associated with authigenic quartz and analcite. Authigenic chlorite develops only in interdistributary bay adjacent to mudstone formations, with mudstone compaction water providing the source of its material. Mg-rich grain replacive chlorite grows in lithic grains and replaces darker minerals in the lithic grains. The work has shown that chlorite in the oil-wetted state often adsorbs bitumen, inhibiting oil recovery and reducing oil production. Systematic studies of the characteristics and genesis of chlorite can provide important insights into the chlorite research and are applicable to the exploration and development of chlorite-rich tight sandstone reservoirs at the front of the braided river delta.

Dolostone Petrology: Unveiling the past through a multi-method thin-section observation

Jino PARK[1]*, Kangwon National University (jinopark@kangwon.ac.kr)
Jongsun HONG[2], Kangwon National University

Abstract

Dolostone (dolomite), comprising almost half of the world's carbonates, presents formidable challenges to geological investigation due to the obliteration of primary sedimentary structures, textures, and fossils during the recrystallization process. This study aims to assess the effectiveness of traditional petrological methods in extracting information from dolostones and advocates for a multi-method thin-section observation approach as the optimal strategy. The instigation focuses on 270 dolostone samples from the upper Cambrian Wagok Formation of Korea, primarily composed of massive dolostone with limited preservation of meso-scale sedimentary structures in the uppermost and lowermost intervals of the formation. Preliminary result on slab observations indicates that around 16% of samples exhibit patchy preservation of meso-scale sedimentary features, which discourages the undertaking of both qualitative and quantitative analyses of carbonate components. Polarized light microscopy reveals partial traces of sedimentary textures in about 13% of thin sections, predominantly showcasing highly crystalline dolomite fabrics. In contrast, visual examination of thin sections using fluorescent plates identifies meso-scale sedimentary structures, including Dunham's classification, in approximately 90% of samples. The 'white card' technique (Folk, 1987) proves valuable in detecting grain compositions and small-scale sedimentary features in about 60% of thin sections. However, this technique is only applied on xenotopic dolomite fabrics rather than idiotopic fabrics or scattered dolomite rhobms of less-dolomitized carbonates because outline of dolomite crystals is emphasized, preventing observation of the original textures. The study underscores the effectiveness of naked eye and 'white card' observations on thin-sections for petrological study of dolostones, emphasizing their complementary nature in elucidating sedimentary information across diverse scales. Consequently, integrating both observation methods maximizes information extraction from massive dolostones.

Stratigraphy and Carbonate Petrology of Permian Thitsipin Formation, Ywa-ngan Township, Myanmar: Implications for Depositional Environment

KYI KYI MAW[1]*, Maubin University (drkyikyimaw65@gmail.com)
KYI KYI MAW[2], Maubin University

Abstract

The research area is situated in Ywa-ngan Township, Shan State (South), eastern Myanmar bounded by 21° 10′ to 21° 15′ and 96° 25′ to 96° 35′. The research emphasizes on carbonate petrology and stratigraphy of Permian Limestone unit to rename formal stratigraphically. They are widely distributed in the eastern and western parts of the area. Petrographically, the rocks of Permian Limestone are classified as bioclastic grainstone, bioclastic wackestone packstone, bioclastic peloidal grainstone, peloidal bioclastic grainstone, bioclastic rudstone and dolomite. Megascopically, it mainly consists of bioclastic limestone, crystalline limestone, micritic limestone, cherty limestone and dolomitic limestone. From XRF analysis, the rocks fall in the fields of limestone, magnesium limestone and dolomitic limestone. Two columnar sections were measured in details. The first section, (Linwe section) is 306m thick, containing at least six microfacies, and second (Hsinsapya section) is 497m thick and consisting of four microfacies. They were grouped into three microfacies associations, representing subtidal, intertidal and supratidal environments. Corals (Ipciphyllum subelegans, Lophophyllidium sp., Pavastehphylum simplex, Pavastehphyllum spongifolium, Iranophyllum sp., Syringopora sp.), Fusulinids (Pseudo fusulina sp., Eoverbeekina sp., Nankinella sp., Rugososchwagerina sp.,? Pseudoschwagerina sp., Kahlerina sp.), Bryozoan (Fenestellina sp. Polypora sp.) and echinoderm indicate that it may be early to middle Permian. The petrographic study, XRF analysis and the stratigraphic criteria in a formal stratigraphic unit point out that the renamed Thitsipin Limestone (Early to Middle Permian) is more suitable than the Thitsipin Limestone Formation (Permian). It was possibly deposited in subtidal, intertidal and supratidal environment with low to high energy condition.

Abstract

Among the fundamental turning points in the history of life, the Cambrian Explosion is of primary interest. Nevertheless, the lack of correlation between exposures, the scarcity of high-precision radioisotope ages, and a generalized endemism have hindered in-depth understanding of the mechanisms that triggered paleoceanographic changes associated with the evolutionary boosts. The Cambrian Explosion time scale can be greatly improved by the identification of Milankovitch-driven climate cycles through cyclostratigraphy.

High-resolution XRF core scanning data of the sedimentary series from the well-preserved Albjära-1 drill core from Scania, Southern Sweden reveals prominent cycles at wavelengths of 0.09, 0.15, 0.5 and 2 m. These wavelengths have similar ratios to the theoretical Cambrian Milankovitch periods and are attributed to the precession (18 kyr), the obliquity (31 kyr), and the short and long orbital eccentricity cycles (100 kyr, 405 kyr). In addition, a prominent cycle at 0.85 m is observed and interpreted as the 173 kyr obliquity modulation. Both the 173 and 405 kyr cycles can be used as “metronomes” (Laskar, 2020). The 173 kyr metronome was selected to build an astronomically calibrated time scale (ATS) for the Miaolingian series. The results allow to evaluate the duration of the trilobite zones Goniagnostus nathorsti (675 kyr), Ptychagnostus punctuosus (1.36 Myr), Ptychagnostus atavus (0.91 Myr), and Ptychagnostus gibbus (812 kyr), the Drumian Stage (2.95 Myr), and the Drumian Carbon Isotope Excursion (DICE) (0.99 to 1.55 Myr). To ensure stratigraphic continuity with Zhao et al.'s (2022) ATS, we incorporated the U-Pb numerical age anchor (486.78±0.53 Ma) below the Cambrian-Ordovician boundary in the

uppermost part of the core.

This updated biostratigraphic framework and δ13Corg profile place the DICE prior to the first appearance of the Wuliuan-Drumian boundary's index taxon P. atavus. This differs from the Wuliuan-Druminan GSSP where the DICE is located above the stage boundary. TOC and δ13Corg profiles combined with our improved biostratigraphy also enable the integration of this research into the Cambrian bio-geochemical framework, which can be used as a reference to calibrate other sections and events.

Abstract

The comprehensive study involving Petrography, Grain Size Analysis, Geochemistry, Clay Mineralogy, and Palynology on a significant number of samples from the Permian to Cretaceous age sediments of the Talchir, Barakar, Motur, Bijori, Pachmari, Denwa, Bagra, and Jabalpur formations in the Satpura Gondwana Basin aims to unravel the paleoclimate, provenance, and depositional environment. This multifaceted investigation employs a detailed analysis of 90 samples each for Petrography and Grain Size, 150 samples for Geochemistry, 91 samples for Clay Mineralogy, and 144 samples for Palynology. QFR plot suggests that sediments of Jabalpur, Denwa and Pachmari deposited in hot, humid climates and Motur, Bijori and Barakar deposited in semi-arid to warm, humid climates. Bagra and Talchir deposited in semiarid to sub-humid climates. Weathering was intense during the deposition of Upper Gondwana as compared to Lower Gondwana sediments. Grain size analysis reveals that sediments of the western & eastern parts of the basin are medium-grained, moderately to poorly sorted, platykurtic to very leptokurtic nature except Jabalpur, Denwa and Talchir formations are fine-grained, well sorted. Chondrite normalized REE pattern of the majority of mudstone samples of all formations display a high LREE/HREE ratio and correlate with relatively felsic provenance of Upper continental crust and matches with granite gneisses supported by Th/U & Th/Co ratio. The high ratios of Th/Sc and Zr/Sc Indicate input of materials from recycled sedimentary provenance in some of the mudstone samples. The trivariate plots of La-Th-Sc, Th-Sc-Zr/10, and Th-Co-Zr/10 suggest passive & active continental margin tectonic settings. However, few samples are falling in the island arc setting. Total REE >210 for all formations of Satpura basin indicates Passive margin (PM) and Eu/Eu*= 0.64 to 0.69 suggests Aden-type continental margin (ATCM) as tectonic setting. The presence of illite and chlorite as inherited minerals from the Talchir Formation suggests a cold and dry climate, presence of Kaolinite suggests a warm and humid climate for Barakar Formation, a warm and humid climate with intermittent spells of arid climate during the deposition of the Motur Formation and a warm and humid as well as warm to arid climate during the deposition of the Bijori Formation. Pachmari Formation is deposited in warm and humid with few semiarid to arid intervals. Studies suggest warm and humid climates prevailed for the lower arenaceous part and hot, semiarid for the upper muddy part of the Denwa Formation. The warm and humid climate was prevalent with semiarid intervals during the sedimentation of the Bagra Formation, while Kaolinite as a major mineral strongly suggests warm and humid paleoclimate during the deposition of the Jabalpur Formation. The palynological study suggests that rich and diversified

vegetation during the deposition of the sediments and the Permo-Triassic boundary is straddling in between the Bijori and Pachmari formations in the area indicating a near correlation of lithostratigraphy and biostratigraphy of the basin with exception of Jabalpur formation due to insufficient palynological evidence. The recovery of glomus from all the formations indicates mainly freshwater input suggesting a riverine depositional environment for the Gondwana sediments.

Detrital zircon geochronology of the basal Taebaek Group: Implications for regional scale provenance dynamics during the initial stage of the North China Platform

Donghyeok KANG[1]*, Seoul National University (aceray1248@snu.ac.kr)
Jusun Woo[2], Seoul National University

Abstract

High-frequency detrital zircon U-Pb data can provide detailed information on how sediment sources and dispersal systems evolved over the stages of the platform development. Regional scale provenance analysis is conducted from the basal Cambrian Taebaek Group, Taebaeksan Basin in the eastern margin of the North China Platform by revealing spatial and stratigraphic variability of the detrital zircon ages. Sediments forming basal coarse-grained units were largely fed from proximal basement rocks. However, as transgression proceeded, sediment sources for the basal units were submerged and buried, resulting in the upland shift of sediment provenance and the influx of sediments from the outboard arc complex. With the ensuing base-level rise, fine-grained sediments from the Gondwana mainland or elsewhere within the Sino-Korean Craton rapidly replaced in-situ sediments in the low gradient western/southern part of the basin resulting in abrupt change in detrital zircon patterns up the sequence. However, detrital zircon populations in the northern/eastern part of the basin, closer to the highland, exhibit consistent local basement signature, even in the fine-grained succession. The variations in detrital zircon patterns likely resulted from complex interplays of changes in topographic conditions and global marine transgression. These together with stratigraphic and sedimentological data, would likely lead to a better understanding of the early-stage basin-filling history of the Taebaeksan Basin and a more comprehensive reconstruction of the entire platform.

Integrated Ichnological, Sedimentological and Geochemical Studies of the Cambrian Kunzam La Formation from Tidong Valley (Kinnaur), Himachal Himalaya: reconstructing the Northern Margin of the Indian Plate

Ranveer Singh Negi[1]*, Birbal Sahni Institute of Palaeosciences (negiranveer@bsip.res.in)

Abstract

The Northern margin of Eastern Gondwana, well-preserved in the sedimentary rocks of Tethyan Himalaya (TH) in North India, exhibits distinct signatures of sequential magmatic events and crustal growth history spanning Precambrian to Cambrian times. While extensive research has been conducted in the Zanskar-Spiti region regarding this time frame, the neighbouring Kinnaur-Kumaon region in the NW Tethyan Himalaya still needs to be explored, representing a significant missing link. Our study aims to address this gap by focusing on the Tidong Valley in Kinnaur. We investigate the Kunzam La Formation from the Cambrian period, employing an integrated approach combining ichnological, sedimentological, and geochemical analyses. Ichnological analyses reveal the presence of the *Psammichnites gigas gigas* ichnozone immediately beneath the Thango (Ordovician) sedimentary layers. Correlating these findings with the adjacent Zanskar-Spiti region suggests a tentative Cambrian Series 2, Stage 4 age for these deposits. The trace fossil assemblages include ichnospecies of *Bergaueria*, *Monocraterion*, and *Psammichnites*, alongside arthropod scratch marks. Notably, no body fossils have been recovered thus far. Sedimentological analysis identifies five distinct lithofacies within the studied area: (i) a prevalent low-angle trough cross-bedded facies with rip-up mud clasts, (ii) wavy (tabular) bedded sandstone facies, (iii) conglomerate facies, (iv) sandstone-siltstone-shale facies, and (v) bedded siltstone facies. Despite the absence of cyclic sedimentation, there is a discernible trend of shoaling upward across the lithofacies succession. Notably, facies commonly associated with offshore environments, such as hummocky cross-stratification and dark shale, which typically harbour abundant trilobite and brachiopod faunal elements in Zanskar-Spiti regions, are conspicuously lacking in the Tidong Valley. The geochemical composition including Rare Earth Elements (La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu) and selected Trace Elements (Sc, V, Co, Ni, Cu, Zn, Ga, Rb, Sr, Y, Zr, Nb, Mo, Cs, Ba, Hf, Ta, Pb, Th, U), obtained from the Kunzam La clastic sediments, was analyzed using a range of analytical tools. These analyses suggest a mixed provenance of major felsic (UCC compositions) nature with minor contributions from basic sources (HFSE-depleted mantle) in continental island arc-type settings located south of the deposition site. Overall, the analyses corroborate each other, suggesting that the Kunzam La Formation in the Tidong Valley was deposited in a shallow-marine, nearshore to upper shoreface environment, proximal to the shoreline where a main river system met the northern margin of the Indian plate during the Cambrian period. The paleoredox condition was highly oxidizing, paleosalinity low, and paleoclimatic conditions were warm and humid during the sediment deposition.

Abstract

Interpretation of bulk sediment geochemistry is one of several approaches for determining sediment provenance, depositional environment, and paleoclimate. This study investigates the value added by bulk sediment geochemical analysis and sedimentology characteristics in interpreting depositional environment in a passive margin clastic basin, the Lower Cambrian shallow shelf sediments of the Yangtze Basin, eastern Yunnan, SW China. The study utilized field outcrops, thin section analysis, major and trace element to investigate the sedimentary environment, provenance, paleoweathering and paleoclimate of the Lower Cambrian Hongjingshao (HJS) Formation (Cambrian Stage 3,~515Ma). The HJS sandstones is composed of 10 lithofacies, including massive and crudely bedded gravel supported by coarse sandstone (Gm), trough cross-bedded sandstone (St), planar cross-bedded sandstone (Sp), ripple cross laminated sandstone (Sr), horizontal bedded sandstone (Sh), scour-fill sandstone (Se), massive sandstone (Sm), fine to medium sandstone with thin bed muddy siltstone (Fl), muddy siltstone (Fsc), and mudstone (Fm). On the basis of these lithofacies, channel fill and over-bank deposits in delta and shallow shelf depositional environment is suggested for HJS Formation. The bivariate diagrams comparing Cr and V ratios with Y and Ni ratios, La and Yb ratios with total REE contents, and La and Th ratios with Hf suggest that the sandstones of the HJS Formation were derived from felsic source rocks in the study area. CIA, PIA and CIW values range from 71.29 to 93.72 indicating an intermediate to intense chemical weathering and a semiarid to humid climate conditions in Cambrian Stage 3.

Spatial variation in carbonate carbon isotopes during the Cambrian SPICE event across the eastern North China Platform

ZHAOPENG WANG[1]*, Shandong University of Science and Technology (zpwang@sdust.edu.cn)
CHEN JITAO[2], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Abstract

The Cambrian SPICE (Steptoean Positive Carbon Isotope Excursion) event is widely reported from the late Miaolingian to the early Furongian, but recent studies imply that the synchroneity and magnitude of the SPICE may be controversial. In order to test the spatial variation of the SPICE, here we present 367 carbonate δ 13 C data from six outcrop sections across a ~700 km transect along the eastern North China Platform. The SPICE is present in all the studied sections, but showing different features regarding the duration and magnitude. An abrupt increase in δ 13 C from ~1.5‰ to 3.5‰ occurs in three Shandong sections, with maximum value present only in a thin (0.5–1.2 m thick) transgressive lag deposit (crudely wave stratified, bioclastic grainstone). In contrast, the δ 13 C record of the Baijiashan and Shashan sections in the Liaoning region displays a gradual increase (~20 m thick) from ~1.5‰ to the maximum value of 4.7‰. Both facies analysis and trilobite collections suggest that the spatial variation of the SPICE in the North China Platform most likely resulted from missing of sedimentary record (with high δ 13 C values) in the Shandong sections as a result of erosion and non-deposition during sea-level lowstand, a possible coeval hiatus prior to the Sauk III transgression in the Laurentian basins. Further high-resolution, integrated studies of sedimentology, biostratigraphy, and sedimentary geochemistry on the SPICE event are required to better understand its nature.

A dendrolite reef in a Cambrian siliciclastic environment, Sesong Formation, Taebaeksan Basin

Jusun WOO[1]*, Seoul National University (jusunwoo@snu.ac.kr)
Sojeong Kim[2], Korea Institute of Ocean Science and Technology

Abstract

In the Korean Peninsula, microbialites, rocks formed by microbial organisms, occur in the sedimentary rocks age from the Neoproterozoic to the Cretaceous. The Joseon Supergroup in the Taebaeksan Basin is a early Paleozoic mixed siliciclastic-carbonate succession deposited in a shallow marine carbonate platform. Microbialites have reported from the carbonate succession of the Joseon Supergroup: the Myobong, Daegi, Hwajeol, Dumugol, Makgol, Duwibong formations.
The Sesong Formation is one of the siliciclastic succession comprising the Joseon Supergroup between the Daegi and Hwajeol formations. The formation has two lithologic divisions of shaley lower part (nodule bearing shale dominant) and sandy upper part (fine-to medium-grained sandstone dominant). The upper part can be subdivided into three intervals according to the grain size of the sandstone and bioturbation intensity. Interval 1, the lowermost interval, is composed mainly of fine grained sandstone with high bioturbation intensity (BI 2-5). Interval 2, is characterized by increased portion of medium grained sandstone and waning of bioturbation index (BI 1-3). The uppermost interval 3 consists of fine- to medium grained sandstone representing weak to moderate bioturbation (BI 1-4).
We report the discovery of dendrolite reef structures from the middle of the Sesong Formation. The outcrop is located on the road cut of road 31 near the Taebaeksan motel. The reef overlies the chaotic conglomerate with sandstone matrix and underlies moderately bioturbated fine- to medium grained sandstone. The exposed width and height of the reef structure are cm and cm, respectively. Continuity is poor and distribution of it is limited only in the limestone conglomerate that intercalates within the sandstone. The dendrolite reef is comprised of upward branching, downward tapering shaped dendroids and bioclastic limestone conglomerate matrices. Further studies, on the microscopic structures, comparison with other dendrolites, and paleogeographic occurrence, will improve not only the understanding about the depositional environment of the Sesong Formation, but also the origin and development of microbialites and their influence on the geological records at that time.

Floating astronomical time scale from the Upper Yangtze Region of South China suggests rapid paleoevnironmental variations during the Hirnantian glaciation

Hanyu ZHU[1]*, Department of Geology, School of Earth and Space Sciences, Peking University (hyzhu@pku.edu.cn)
Mingsong Li[2], Key Laboratory of Orogenic Belts and Crustal Evolution, MOE, School of Earth and Space Sciences, Peking University
Junpeng Zhang[3], State Key Laboratory of Palaeobiology and Stratigraphy, Center for Excellence in Life and Paleoenvironment, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Abstract

The Hirnantian glaciation during the transition from the Late Ordovician to the Early Silurian witnessed a set of critical paleoenvironmental events, especially the Late Ordovician Mass Extinction (LOME). Though the preliminary framework of the Hirnantian Age has been established, however, the detailed time scale of the Hirnantian Stage remained uncertain. The uncertainty of the chronostratigraphy was primarily attributed to the scarcity of precise radiometric dating results. A floating astronomical time scale (FATS) constructed using cyclostratigraphy can provide independent estimation on the time span of geological events. High-resolution abundance data from X-ray fluorescence core scanning (XRF-CS) of the specific drill cores recording the paleoenvironmental signals around the Hirnantian from the Yiwan-1 (YW-1) Well and Shuanghe-1 (SH-1) Well in the Upper Yangtze Region has been correlated to the current stratigraphic framework. We analyzed and processed the two data sets with modern methodologies. We identified the existence and stability of the 405,000 years (405 kyr) long eccentricity quasiperiodic cycles in multiple sedimentary signal channels of the two XRF-CS data sets through novel statistical testing methods. Besides, we built a regionally consensual FATS from the 405 kyr long eccentricity signal in the YW-1 drill cores with new tools including dynamic filtering and aligned tuning. Our new astrochronological estimation suggested a shorter duration for the Hirnantian glaciation and more rapid variations of the paleoenvironment processes. Our findings underscored the necessity to reevaluate the current chronostratigraphic framework of the Hirnantian Stage and the demand to examine the hypotheses on the mechanism of the paleoenvironmental changes during the Hirnantian glaciation.

Provenance changes of the lower–middle Cambrian successions in the Taebaek Group, Korea: Environmental controls on source rock changes

Hyojong LEE[1]*, Korea Institute of Geoscience and Mineral Resources (hyojonglee@kigam.re.kr)
Min-Kyu OH[2], Chungnam National University
Taejin CHOI[3], Korea National University of Education
Jeong-Hyun LEE[4], Chungnam National University

Abstract

The Myeonsan and Myobong formations (lower–middle Cambrian) from the eastern Sino-Korean Block were deposited in terrestrial–nearshore to tide-dominated marine environments during a second-order transgression. Analyses of detrital zircon (4 samples) and whole-rock geochemistry (25 samples) from these successions (ca 120 m thick) at the Sangdong section demonstrate the influence of depositional environments and sea-level changes over changes in provenance. Detrital zircon analyses reveal three major source rock ages: Cambrian (ca. 520 Ma), Meso–Neoproterozoic (ca. 600–1600 Ma), and Paleoproterozoic (ca. 1800–2600 Ma), which indicate a hypothetical syndepositional volcanic arc, Gondwana, and Sino-Korean sources respectively. Among the four samples collected from the bottom to the top of the succession, the lower two (at 1 and 23 m) are characterized by Cambrian and Paleoproterozoic ages, while the upper two (at 81 and 112 m) show dominant Meso–Neoproterozoic with subordinate Cambrian ages. Whole-rock geochemistry analyses show an abrupt transition from mafic to felsic composition at ca. 60 m above the basement. This provenance change can be correlated to changes in the depositional environment. The Myeonsan and lower Myobong formations were deposited in tidally influenced estuary and intertidal environments, where sediments would have been derived from the volcanic arc by tidal currents as well as by fluvial input from nearby basement rocks (Sino-Korean Block). The transition from mafic to felsic composition occurs in the middle of a thick shallow subtidal succession, coinciding with a supposed shift from deepening to shallowing. The sediments in the upper Myobong Formation (shallow subtidal to shoal) possibly reflect stronger effects of coastal currents and/or a shift in the sediment routing system in the source area, resulting in increased input from distant felsic rocks (Gondwana), supplemented by sediment input from the volcanic arc via tidal currents. The results of this study underscore the importance of depositional environments and sea-level changes in provenance studies, cautioning that careful interpretation is necessary to understand their paleogeographic implications.

Recycling of the Appalachian Signature in DZ U-Pb Records of Phanerozoic North America and Barriers to Transcontinental Sediment Transfer

Isaac ALLRED[1]*, Brigham Young University-Idaho (allredi@byui.edu)

Abstract

The detrital zircon (DZ) U-Pb signature of the Appalachian-Ouachita orogenic system is dominated by Grenville (ca. 1250–950 Ma) and Appalachian (ca. 500–275 Ma) age groups and dominates the Phanerozoic record of North America. This study compares Pennsylvanian to modern DZ U-Pb data from across North America and demonstrates a persistent Appalachian signature, including a recycled Appalachian signature across western North America. Lower Pennsylvanian deposits proximal to the Appalachian orogen are 50–75 % Appalachian- and Grenville-age DZ, representing the key component in the primary Appalachian signature. It remains unclear how the Appalachian signal was propagated to the West, but Pennsylvanian Jackfork Group and other Ouachita Basin deposits represent a depositional sink and a barrier to transcontinental sediment transfer. Instead, Appalachian-age DZ in Carboniferous western Laurentian strata may have been derived from the northern Appalachians in the United States and Canada or the Ellesmerian orogen.

Triassic DZ samples document transcontinental fluvial systems with headwaters in the Ouachita-Marathon orogen that reached the western Laurentian margin. Subsequent Jurassic-Cretaceous samples, however, indicate drainage reversal due to the rise of the Mesozoic Western Cordillera. A persistent Appalachian signature exists in these western-sourced, eastward-flowing systems—a phenomenon that continues to the present. Samples are frequently composed of >40% Appalachian- and Grenville-age DZ. However, none of these systems are interpreted to be sourced by primary Appalachian or Grenville terranes, suggesting a recycled Appalachian signature. The persistent Appalachian signature, originally sourced by the linking of two orogenic terranes, continues to be the dominant contributor in the DZ record of North America.

Depositional environments of the Dongjeom Formation (upper Cambrian to lower Ordovician) in the Taebaeksan Basin in North China Platform: spatial heterogeneity of facies in wave-dominated shallow marine environments

Seungbeom AHN[1]*, Seoul National University (sksm1357@snu.ac.kr)
Jusun Woo[2], Seoul National University

Abstract

The Dongjeom Formation is a thick sandstone unit intercalated within carbonate-dominated formations in the Taebaeksan Basin located in the easternmost part of the North China Platform. In order to understand stratigraphic and tectonic implications of the sandstone unit in between carbonate units, a detailed field mapping and sedimentologic investigation were conducted in seven sections which represent 30-km-wide exposure of the formation in the southern part. The Dongjeom Formation was deposited under wave-dominated shallow marine environments represented by four facies associations: FA1 (offshore transition zone), FA2 (lower shoreface), FA3 (middle to upper shoreface), and FA4 (mid ramp). FA1 is characterized by limestone and very fine sandstone couplet and laminated very fine sandstone with intercalating limestone conglomerate. FA2 comprises alternating bioturbated fine sandstone and low-angle cross-laminated fine sandstone. FA3 exhibits well-sorted and rounded massive medium sandstone or calcareous cross-bedded coarse sandstone. FA4 is composed of limestone shale couplet with intercalating limestone conglomerate. Two facies successions (FS1, FS2) are defined by those showing coarsening-upward trends with sharp upper boundary contact interpreted as each regressive deposition ended up by a transgression event. Facies associations in FS1 are spatially well correlated, but FA3 in the upper part varies in thickness in the sections and is not shown in the western part. Siliciclastic shelf facies are completely changed into carbonate ramp facies (FA4) at the uppermost part of FS2, except for a lens of sandy coarsening upward succession occurring in the eastern part. This discontinuous distribution of facies in shallow marine environments deviates from the standard linear facies belt of a wave-dominated environment. The heterogeneous facies development is inferred to be due to local differences in sedimentation rates. Understanding the origin of the coarse siliciclastic sediments is important for reconstructing paleogeography and tectonic settings.

Preliminary study of spatiotemporal variability of sandstone compositions for early Paleozoic sandstones in the Bowers Terrane, northern Victoria Land, Antarctica

HONGWOO KIM[1]*, Seoul National University (asd1641@snu.ac.kr)
JUSUN WOO[2], Seoul National University

Abstract

The Bowers Terrane, located in northern Victoria Land, Antarctica, is represented by early Paleozoic sedimentary rocks, the Bowers Supergroup which consists of the Sledgers, the Mariner, and the Leap Year groups in ascending order. These successions record the depositional history of the eastern Gondwana margin in the early Paleozoic and serve as a significant puzzle piece in interpreting tectonic events in the Gondwana and surrounding landmasses. In this study, we analyzed the sandstone composition of the Bowers Supergroup using point-counting methods to visualize spatiotemporal variability on the QFL triangular diagrams. The Molar Formation (Sledgers Group) at Reilly Ridge, consistent with previous studies, shows a transitional continental to recycled orogenic composition. The Spurs Formation (Mariner Group) at Reilly Ridge and Eureka Spurs has a recycled orogenic to transitional arc composition. This is similar to the known composition of the Molar Formation, which means the source area didn't change dramatically. However, in Eureka Spurs, south of Reilly Ridge, a more mature composition is observed and leading up to Eureka Formation (Mariner Group). The South End Member (Mariner Group) overlying the Spurs Formation at Reilly Ridge represents recycled orogenic composition with higher matureness than the Spurs Formation at Reilly Ridge, but lower than the Spurs Formation at Eureka Spurs. The sandstone clast composition of this member interestingly resembles the sandstone clast of the Carryer Conglomerate (northern Victoria Land) and Lockett/Dead Goat Conglomerate (New Zealand), but differs from the sandstone clasts of the Douglas Conglomerate (central Transantarctic Mountains), all of which were considered to be located in the eastern margin of Gondwana during the early Paleozoic. The Reilly Conglomerate (Leap Year Group) at Reilly Ridge shows a recycled orogenic composition. Camp Ridge Quartzite (Leap Year Group) represents craton interior composition at Leitch Massif and recycled orogenic at Eureka Spurs. Considering good sorting and roundness of Camp Ridge Quartzite at Leitch Massif, the composition is thought that the influence of depositional mechanism played a significant role, such as differential reworking, rather than changes in the source province. Spatiotemporal variability of sandstone clast composition could provide a better understanding of the source area of the sandstone and deposition processes in the Bowers Terrane.

Provenance of Detrital Zircons in Zealandia: Implications of a Musgrave Province Source and Potential Link to the MAPCIS Impact"

Daniel Patrick CONNELLY[1]*, MAPCIS Research Project 4815 Covered Bridge Rd. Millville, NJ 08332 USA (danielconnelly@comcast.net)

Abstract

Detrital zircons offer insights into the geological history and tectonic evolution of sedimentary basins. This presentation reviews the detrital zircons from studies of Zealandia a submerged continental in the southwestern Pacific Ocean, with a focus on their suspected provenance from the Musgrave Province in central Australia. The results reveal a dominant population of detrital zircons with age peaks corresponding to the Mesoproterozoic and Neoproterozoic eras, characteristic of the Musgrave Province. These findings suggest a significant sediment input from the Musgrave region to Zealandia during the late Proterozoic to early Paleozoic. The findings also suggest a unique method of rapid long distance transport preserving many euhedral zircon crystals.

The MAPCIS impact, which stands for the Massive Australian Precambrian-Cambrian Impact Structure, refers to a large impact structure formed by an asteroid or comet at the end of the Neoproterozoic in the Musgrave Province of Central Australia during the time it was a shallow sea known as the Centralian Superbasin. Detrital zircons found in Zealandia with a Musgrave provenance could potentially be linked to the MAPCIS impact through the transport of zircon-bearing sediments. The impact event would have generated enormous amounts of energy, leading to the ejection and redistribution of material over vast distances. Zircon grains from the Musgrave Province could have been transported to Zealandia as part of the sedimentary fallout from the impact, thus providing a chronological link between the two regions.

Further research, including detailed sedimentological and geochemical analyses, would be needed to establish a more definitive connection between detrital zircons, the Musgrave Province, and the MAPCIS impact in the context of Zealandia's geological history.

Unveiling the geological significance of the Northern Gondwana glaciofluvial deposit: A geochemical approach by coupling rare-earth element and trace element geochemistry

Adhipa Herlambang Pamularso[1]*, KFUPM (adhipa.herlambang@kfupm.edu.sa)
Ardiansyah Ibnu Koeshidayatullah[2], KFUPM
Khalid Abdussamad Hassan Al-Ramadan[3], KFUPM

Abstract

The Sarah Formation represents a glaciofluvial sedimentary deposit formed during the end of the Ordovician ice age along the Gondwana Margin, and this period of glaciation initiated the carving of valleys and the formation of extensive paleo valleys. Stretching from westernmost North Africa to the Arabian Peninsula, the Sarah Formation is part of a discontinuous belt of outcrop deposits. Notably, it serves as a potential tight gas sandstone reservoir in the Rub' al Khali Basin and other basins in Saudi Arabia. However, despite its significance, global studies on the geochemical data, depositional settings, and spatial distribution of the Late Ordovician glaciofluvial sedimentary formation remain sparse. To address this gap, our study aims to unravel the provenance and tectonic settings of this formation using geochemical records. In this study, we conducted inductively coupled plasma mass spectrometry (ICP-MS) analysis on samples collected from six outcrops in two paleo valleys of the Sarah Formation in NW Saudi Arabia. By analyzing the composition of major, trace, and normalized rare earth elements (REEs) in conjunction with detailed stratigraphic measurements, we aimed to understand the provenance, paleoenvironment, and tectonic settings associated with the glacial events. Our results were compared with previous studies on Late Ordovician glaciofluvial sedimentary formations in various locations to enhance our understanding of sediment provenance and tectonic settings. The analysis revealed that Sarah sandstone is enriched in Ba, Zr, Sr, Zn, and Rb, with relatively high concentrations of V, Cu, B, Cr, and Pb. The total REE (ΣREE) content ranged from 24.7 to 215.9 ppm, showing enrichment in LREE and a slightly negative Eu anomaly. The high LREE/HREE ratios and Eu anomalies suggest that the sediment was mainly derived from felsic igneous rocks. Furthermore, the low (Gd/Yb)CN ratios indicate provenance from Post-Archean strata. In contrast, Ti/Zr and La/Sc ratios suggest deposition in a passive continental margin setting, consistent with the tectonic setting of North Gondwana during the Late Ordovician. On a broader scale, Late Ordovician glaciofluvial sediments from different locations share similar provenance but were deposited in slightly varied tectonic settings. This research highlights the usefulness of major, trace, and rare earth elements in understanding geological processes. It could aid in exploring and developing tight gas sandstone reservoirs within similar formations.

Late Sinian-Early Paleozoic Lithofacies Paleogeographic Characteristics and Exploration Significance of the South Yellow Sea Basin, China

Huiyong LI[1], CNOOC China Limited,Tianjin Branch
Ying GUO[2]*, CNOOC China Limited,Tianjin Branch (350426124@qq.com)
Qingxun WU[3], CNOOC China Limited,Tianjin Branch
Panpan SHI[4], CNOOC China Limited,Tianjin Branch
Zhiqiang LI[5], CNOOC China Limited,Tianjin Branch

Abstract

The South Yellow Sea Basin, located above the ancient land nucleus of the Lower Yangtze Platform in China, with thick Late Sinian to Early Paleozoic carbonate and clastic sedimentary layers, possesses excellent exploration potential. Lithofacies paleogeographic conditions play a significant control role in the development of source rocks, reservoirs, and hydrocarbon accumulation from the Upper Sinian to the Lower Paleozoic. In this study, drilling, field outcrop, seismic, and analytical data from the South Yellow Sea and the Lower Yangtze Land were systematically studied to understand the late Sinian to early Paleozoic lithofacies paleogeographic evolution and the geological significance of oil and gas. The research indicates that during the late Sinian to early Paleozoic, the study area experienced evolutionary stages of margin platform and foreland basin paleogeography. Late Sinian to Middle Ordovician, the study area was dominated by margin platform sedimentation, inheriting the global supercontinent rifting background, with rift basins and ancient uplifts distributed alternately, forming a pattern of dual basins and dual uplifts. Late Ordovician to Silurian, with the collision and amalgamation of the Yangtze Plate and the Huaxia Plate, the study area gradually transformed into a foreland basin paleogeographic pattern. The different paleogeographic patterns of basin-uplift and foreland basin control the development modes of two types of source rocks and reservoirs in the study area. The paleorift troughs and the post-uplift depression of foreland basin are concentrated areas of high-quality source rock development, with the Lower Cambrian and Upper Ordovician to Lower Silurian source rocks being the most enriched. The platform margin reef-flat facies on both sides of paleorift troughs are favorable areas for the development of high-quality dolomite reservoirs from the Upper Sinian to the Cambrian, forming a good reservoir-seal combination with Lower Cambrian and Silurian mudstones. The inherited ancient uplifts serve as advantageous directions for oil and gas migration in the study area, controlling the accumulation and reservoir formation of oil and gas from the Upper Sinian to the Lower Paleozoic, providing a favorable direction for oil and gas exploration in the study area.

The paleotectonic and paleogeography reconstructions of the Tarim basin during the Neoproterozoic

Bizhu HE[1]*, Chinese Academy of Geological Sciences (hebizhu@cags.ac.cn)

Abstract

The tectono-sedimentary development of the Neoproterozoic of the Tarim Basin is important for understanding the basin initiation process and for the regional ultra-deep/deep oil and gas exploration. Due to the deep burial and data scarcity, it is extremely difficult to research the deep buried areas of the basin, and data interpretation can be ambiguous. This study, based on comprehensive analyses of drilling data and newly reprocessed seismic reflection data collected across the basin, reveals that the Tarim Basin experienced at least three tectonic cycles during the Neoproterozoic and developed three super stratigraphic sequences and 7-9 stratigraphic sequences. The distribution of sedimentary facies of the Neoproterozoic in the basin and its margin vary greatly, constrained obviously by Neoproterozoic rift depressions. The basin developed shelf facies, glacier facies, basin facies, carbonate platform facies, tidal-flat facies, fan-delta facies, littoral and shallow sea facies, alluvial-fluvial facies, and igneous rock facies. Results on the structural architecture and spatial distribution of unconformities during the Cryogenian Early Cambrian reveal that the tectono-sedimentary frameworks of the basin margin and deep buried area are formed in an extensional environment. The main unconformity types include angular unconformity with low-angle and monocline structures, progressive syn-tectonic angular unconformity, fault-controlled unconformity, and para-conformity, and they are observed in every rift depression and at different locations. The paleotectonic and paleogeography of the basin before the deposition of the Ediacaran and the Cambrian are reconstructed based on sequence stratigraphy, Neoproterozoic fault activity, unconformity architecture, seismic stratigraphy, and wave impedance inversion property data, which show that the distribution of various sedimentary facies zones is related to the developments of rift depressions and subsidence centers and the differences of structural deformations. In response to the subduction-related outgrowth and the breakup of Rodinia, and the assembly of Gondwana, the Tarim Basin experienced three evolutionary cycles in the Neoproterozoic: initiation of deep rift depressions (900-760 Ma), development of deep rift depressions (~750-630 Ma), and rapid extensions and declining of rift depressions (630-520 Ma). Correspondingly, the Tarim block underwent subduction-related back-arc extension, continental rift, and passive continental margin transformations during the Neoproterozoic. The Ediacaran to Cambrian transition is an important period where the Tarim block transformed from continental-rift/rift-depression basins into a unified cratonic basin. This is evidenced by the unconformity between the Cambrian and the Ediacaran or pre-Ediacaran across

the basin and covered by the Lower Cambrian further.

Sedimentation history and U-Pb detrital zircon age from Paleoproterozoic Mahakoshal back-rift basin developed during the evolution of Central Indian Tectonic Zone, India

ADITI SHARMA[1]*, Department of Geology, University of Delhi, Delhi, India (aditisharma.res@gmail.com)
PARTHA PRATIM CHAKRABORTY[2], Department of Geology, University of Delhi, Delhi, India; Hiroshima Institute of Plate Convergence Area Research, Hiroshima, Japan

Abstract

Sedimentation pattern in subduction-related rift basins, developed in Proterozoic orogenies, often not well understood due to modification of grain size and erasure of primary sedimentary structures due to subsequent deformation and metamorphic overprinting. The Parsoi Formation of the Paleoproterozoic Mahakoshal Group of Central Indian Tectonic Zone (CITZ), despite being metamorphosed in green schist facies grade, offers a reasonable scope to understand the typicality of sedimentation pattern in such a back-arc rift setting using process-based sedimentology aided by detrital zircon geochronology. In a west-east transect, the Parsoi Formation record i) poorly-sorted granular sandstone with trough cross-stratification, restricted in the north and north-western part of the basin (braided channel deposits), ii) polymictic conglomerates (mass flow-I/MF-I) and amalgamated/isolated massive to crudely normal-graded (meta) sandstone (mass flow-II/MF-II) in the north-west and their wedging towards east, iii) heterolithic (meta) sandstone-shale alternation with laterally extensive coarse/ medium-grained, massive/ normal-graded sandstone in the middle and eastern part, iv) thin-bedded fine sandstone of turbidite origin encased in shale (phyllite) in the east, (ii, iii, and iv are identified as deltaic mass flows of varied rheology in a proximal- distal relation) and v) medium-grained well-sorted sandstone with unequivocal wave signature at the southern margin of the basin (wave- and tide-dominated shoreface). Spatial facies distribution bear indication of sedimentation in a half-graben like basin setting where conglomerates, coarse sandstones define the footwall part and medium grained (meta) sandstones of shoreface origin record sedimentation history of hanging wall part.

Detrital zircon geochronology from Parsoi footwall and hanging wall sediments allowed validation of a riftogenic half-graben sedimentation model. Whereas fluvial sandstone clustered under three major modes viz 3.0 Ga-2.89 Ga, 2.1 Ga-1.9 Ga, and 1.85 Ga-1.71 Ga, MF-I shows peak of 3.3-3.1 Ga and 2.7-2.5 Ga and MF-II shows a major peak of 1.70 Ga with a number of moderate to subdued >2.50 Ga peaks. No grain with <2.50 Ga age from the MF-I, and absence of 2.0 Ga age grain in MF-II is noteworthy. Consideration of all geochronology data allowed understanding that i) maximum depositional age for the MF-I is ~2.5 Ga, that for the MF-II is ~1.7 Ga, hence, MF-I and MF-II are neither contemporaneous nor cogenetic, ii) absence of ~2.0 Ga zircon in MF-II despite the presence of these grains in fluvial deposits at this section suggest non-

reactivation of ~2.0 Ga provenance at the time of MF-II deposition. A comparison with geochronology ages described from Bundelkhand and Bastar cratons allowed zero down the delivery of detritus in the MF-I from the Bundelkhand craton, whereas in the footwall at the south-eastern part of the basin from the Bastar craton. The MF-II possibly records a mixing of detritus from both the craton. A clear asymmetry in facies association development pattern and detrital zircon geochronology is documented where wedge-shaped coarse-grained delta developed in fault-bound footwalls of rift in the north-northwest because of steep gradient and high bathymetric differential. Mass flow units in the delta (exposed at different studied sections) may be contemporaneous in a broad sense, but certainly not cogenetic.

Tracking Middle and Late Jurassic environmental and sea-level changes in tropical Tethys Ocean

Antun HUSINEC[1]*, St. Lawrence University (ahusinec@stlawu.edu)

Abstract

The Middle and Late Jurassic was a prolonged period of warm greenhouse climate punctuated by cooler episodes, with long-term (2nd-order) sea-level highs at the Bathonian-Callovian, and Kimmeridgian-Oxfordian boundaries. The generally warm climate of the Tethyan tropics and subtropics was favorable for the growth of numerous carbonate platforms in the Tethyan Ocean, which acted as dip-sticks to sea-level oscillations while recording carbon-isotope fluctuations of the platform waters. Here we focus on the relatively continuous, ~1.9-km-thick, ~30 myr record of the Middle and Upper Jurassic Adriatic Carbonate Platform in southern Croatia. We logged in detail nine road-cut and mountain-side sections (~1,900 m total thickness), and sampled lime mudstone for C- and O-isotopes. The δ13C profiles were generated to help constrain the biostratigraphic ages, matching the excursions with those on published δ13C profiles. Identified excursions include the BjBaE (Bajocian-Bathonian), CaOxBE (Callovian-Oxfordian boundary), EOxE, and MOxE (Early and Middle Oxfordian). The similarity of the absolute δ13C and limited evidence of meteoric diagenesis below the unconformities, suggests that the studied carbonates likely preserved the original δ13C signature. The new continuous Adriatic Carbonate Platform δ13C curve may potentially serve as a standard for coeval Tethyan platforms and highlights the potential of thick platform successions as repositories of sea-level changes and carbon isotope fluctuations over long time intervals.

The succession preserves a ~ 30 myr record of carbon-isotope and sea-level fluctuations along the southern Tethyan margin. Three Jurassic 2nd-order sequences (Jurassic supersequences, JSS) can be recognized: JSS2 (Toarcian to basal Callovian), JSS3 (Callovian-Kimmeridgian), and JSS4 (Tithonian). They consist of cyclic subtidal interspersed with highly cyclic peritidal units. Poorly cyclic subtidal intervals commonly occur within the 2nd- and 3rd-order transgressive systems tracts: the upper Toarcian-lower Aalenian interval, a short interval just above the middle Bathonian and in the basal Callovian, the thick Oxfordian interval, much of the lower Kimmeridgian, and the lower Tithonian. Highly cyclic peritidal units are associated with long-term highstands in the upper Bajocian-lower Bathonian and short intervals in the upper Kimmeridgian, and with a long-term sea-level fall in the upper Tithonian. The integrated high-resolution sequence-stratigraphy tied to δ13C chemostratigraphy of the Adriatic Platform provides a framework that can help us better understand and track the environmental and sea-level changes in the tropical Tethys Ocean during the Middle and Late Jurassic.

Morgan L Blades[3], University of Adelaide
Darwinaji Subarkah[4], University of Adelaide

Abstract

The Proterozoic Birrindudu Basin was deposited across an expanse of 36000 km2 in the northwestern Northern Territory. Despite its size, it remains one of the least explored basins in the NT and lacks a robust chronostratigraphic framework. The Birrindudu Basin shares lithological and chronological similarities with the McArthur Basin and sedimentary successions of the Tomkinson Province. These three Paleo-Mesoproterozoic, intra-cratonic basins have been suggested to be interconnected at the time of deposition to form a superbasin system, informally named the greater McArthur Basin. To describe such regionally extensive multiphase systems, the sedimentary successions of these basins have been divided into five basin-scale, non-genetic depositional packages. In stratigraphic order, they are: - the Redbank, Goyder, Glyde, Favenc, and Wilton packages. The focus of this study is the Limbunya Group of the Birrindudu Basin which has been placed within the Glyde Package (ca. 1660–1610 Ma) based on geophysical and sedimentological correlations. It comprises a succession of cyclic carbonates and siliciclastic rocks, this study aims to reconstruct the sedimentary environment of the group using petrography and bulk geochemistry of the shales.

Considering the greater dominance of shales (clay mineral factories) in Earth's sedimentary record, using clay minerals as paleo-climate proxies becomes imperative. They have long been used as indicators of paleo-climatic conditions because of their chemical composition and structure that vary with their depositional environment. However, clay mineralogy fails to distinguish between the clays of different origins (continental-derived detrital, hydrothermal, burial, authigenic, etc.), which commonly show a distinctive particle morphology. In this study, we petrographically differentiate the various clay origins within the shales of the Limbunya Group and make use of textural evidence to draw paleo-environment inferences. Further, these interpretations are tested with independent geochemical indicators to track paleo-climate changes temporally. The shales are analysed for major and selected trace elements (V, Cr, Mo, Co, Ni, Cu, Th, U), including the REE to get insights regarding the source rock composition, weathering, and paleodepositional conditions.

The lower Limbunya Group rocks lack any reliable age constraints, through this study, we provide in situ Rb–Sr dating (LA-ICP-MS/MS) results of early diagenetic illites from lower Limbunya shales, recovered from the well, DD90VRB2 in the Birrindudu Basin. The obtained geochronological data help establish age correlation with the other Glyde Package sequences of

the greater McArthur Basin.

Formation of diamictite by fault-controlled redeposition of concretions

Dmitrii ALEKSANDROV[1]*, IPGG SBRASS (lex_2706@mail.ru)

Abstract

Diamictites form by a variety of processes including, but not limited to glaciomarine deposition, tectonic activity, or sediment gravity flows. The term “diamictite” was introduced by Ramsay in 1855 for boulder deposits of the Permian age in England that were thought to be indicative of an as ice age, although there has been much controversy over their interpretation. Many formations which are, or have been, interpreted to have formed by glaciations are documented from the Archean, Proterozoic, and all periods of the Phanerozoic. Sometimes this information tempts researchers to interpret diamictites as glacial deposits influencing palaeoclimatological and palaeogeographical reconstructions. Frequently, mainly data supposed to be relevant for the current interpretation are reported. These biases have in some cases prevent alternative interpretations from being fully investigated. Therefore the features which are described in the literature often don’t give full view about formation than can mislead another researchers. Due to the growth of knowledge, observations made 30–50 years ago may now be of particular interest. Neoproterozoic diamictites from the south-western margin of the Siberian Craton are no exception to this. Late Neoproterozoic strata of presumed glaciogenic origin of the Marnya Formation, Oselok Group cropping out 2-km along the Uda River in the Eastern Sayan Ranges, south-western Siberia have received considerable attention due to the presence of at least three distinctive diamictite units. The lower diamictite unit (Karapchetui Member) is in subvertical contact (previously interpreted as a glacial valley) with stratigraphically older strata of the Tagul and Ipsit formations of the Karagas Group, and is represented by a wedge-shaped unit of breccia that hosts numerous ellipsoidal sandstone bodies (previously thought to be boulders). Based on detailed sedimentological observations, the boulders can be reinterpreted as early diagenetic sandstone concretions exhumed and redeposited from the Ipsit Formation when the latter was still uncemented and easily erodible. Tectonic compression, faulting and localised continuous syndepositional uplift led to exhumation of the concretions. In the process of redeposition, exfoliating concretions produced abundant debris that provided clasts for the breccia deposit. The Karapchetui diamictite, therefore, can serve as a sedimentary archive of a previously unrecognised episode of late Neoproterozoic tectonic activity at the south-western margin of the Siberian Craton. This research was supported by the Russian Science Foundation (project 23-17-00202).

Millennial scale marl-limestone rhythmites in the Middle Cambrian (500 My) Marjum Formation (Utah, USA) and their modulation by Milankovitch cycles

Damien PAS[1]*, University of Lausanne (damien.pas@unil.ch)
Maya Elrick[2], University of New Mexico
Anne-Christine Da Silva[3], University of Liege
Linda Hinnov[4], George Mason University

Abstract

Middle Cambrian offshore deposits of the Marjum Formation (Drumian; 504.5 Ma to 500.5 Ma; Peng et al., 2020) are characterized by four scales of superimposed cyclicity defined by variable abundances of fine siliciclastics versus limestone; these include the limestone-marl couplets (or rhythmites; 5-10 cm) which are bundled into parasequences (1-2 m), and small-scale (5-10 m) and large-scale (20-40 m) sequences. Time series analysis of SiO2 and lithologic rank stratigraphic series reveals cycles consistent with Milankovitch cycles with periods corresponding to Cambrian orbital eccentricity (20 m, 405 ky; 6 m, 110 ky), obliquity (1.8 m, 30 ky), and climatic precession (1.15 m, 18 ky). Astronomical calibration of the lithologic rank series indicates that the main sub-Milankovitch cycle at 0.065 m has a period of approximately 1 ky and corresponds to the basic rhythmite couplet. All scales of cyclicity are interpreted to be the result of wet vs. dry monsoonal climate oscillations controlling the abundance of fine terrigenous sediment influx to the basin. A plausible millennial-scale climate driver is solar activity. These results provide one of the oldest known geological candidates for solar-influenced climate change modulated by Milankovitch forcing.

Microbial induced sedimentary structures (MISS) from the Paleoproterozoic Gwalior basin, Central India

PRITAM PARITOSH PAUL[1]*, Department of Geology, University of Delhi, Delhi, India-110007 (pritamgeo@gmail.com)
Partha Pratim Chakraborty[2], Department of Geology, University of Delhi, Delhi, India-110007
Arvind Kumar Singh[3], Precambrian Palaeobiology Laboratory, Birbal Sahni Institute of Palaeosciences, Lucknow, India-226007

Abstract

A Proterozoic sedimentary succession often offers a unique scope to study the nature of biosphere in the early Earth history and compare them with expected Martian analogs. The Precambrian biosphere was mostly occupied by algal and microbial life. The Paleoproterozoic Gwalior basin exposes such a sedimentary succession in peninsular India where the evidences of early life is preserved within the siliciclastic rocks in the form of microbial-induced features. The Gwalior Group is represented by ~1.8 km thick unmetamorphosed and undeformed lithopackage hosted in the North Indian shield. It is constituted of both clastic (Par Formation) and chemical (Morar Formation) sediment successions, in order of superposition. The Par Formation is arenaceous and broadly represented by conglomerate, coarse-grained granular sandstones, and sandstone-shale heterolithics, whereas the overlying Morar Formation is essentially chemogenic represented dominantly by Banded Iron Formation (BIF) and ferruginous shale with limestone in subordinate volume. The siliciclastic Par Formation is represented by an early retrogradational succession marked by successive superposition of continental alluvial fan/braided fluvial, fluvial-tidal, and tidal shelf facies succession. A late Progradation in the Par succession is documented in the inner shelf to wave-dominated middle/upper shoreface transition. Unique arrays of microbial-induced sedimentary structures (MISS) are documented from the siliciclastic inner shelf to middle/upper shoreface sandstone of the Par Formation. These structures include (a) Patchy ripple, (b) Keniya structure, (c) palimpsest ripples (d) Sand cracks, and (e) microbial chip on the surface of patchy ripple.

Characterization and Development Patterns of Different Types of Karst Fracture-Cave Systems under Multi-Factor Controls: A Case Study of the Lungu 7 Area in the Tarim Basin.

Xiangbo ZHANG[1]*, China University of Petroleum (East China) (B23010041@s.upc.edu.cn)
Chengyan Lin[2], China University of Petroleum (East China)
Guoyin Zhang[3], China University of Petroleum (East China)
Lihua Ren[4], China University of Petroleum (East China)
Yanan Sun[5], China University of Petroleum (East China)
Chunmei Dong[6], China University of Petroleum (East China)

Abstract

The deep Ordovician carbonate reservoirs in the Lungu 7 area of the Tarim Basin exhibit a diverse array of genetic types and complex structural characteristics in karst fracture-cavity systems. Multiple regulating forces work together to cause superimposed development in karst fracture-cave systems, leading to ambiguous developmental patterns and difficult classification of different kinds of karst systems. Based on field geological outcrops, logging, seismic and other data, the Ordovician paleo-morphology, paleo-hydrology and paleo-structural conditions in the Lungu 7 area have been restored. The spatial distribution characteristics and main controlling factors of different types of karst fracture-cave systems have been described. The compositional units of karst fracture-cave systems have been identified, and the geological models of the development of different types of karstic fracture-cave systems have been established. Firstly, the paleo-morphology of the study area was restored by the "impression method". Based on modern karstic theory, the karstic geomorphic units and micro-geomorphic units were identified. Furthermore, 13 near-NS-direction surface water systems were interpreted based on the micro-morphology. Secondly, the characteristics of three types of faults in the study area, which are nearly NW-SE, nearly NE-SW and nearly EW, are described in detail using deep learning technology. Integrating the geological structural movements and seismic attribute responses within the study area, additional characteristics of the fractures were further elucidated. After comprehensively considering the distribution patterns of karst fissures and caves in the study area and the main controlling factors, the ancient karst system in the study area is divided into four types: paleo-karst, residual-hill karst, paleo-channel karst and faulted karst system. (1) The paleo-karst systems are mainly distributed in the epikarst zone, within 70m below the weathered crust of Ordovician, and are composed of waterfall holes, fault systems, corroded holes and caves. Karst water flows into the surface river along the surface cracks and in the direction of the unconformity slope. (2) The residual-hill karst system is mainly developed in the vadose karst zone, distributed in the high and thick-stratum residual hills. It is significantly affected by the ancient geomorphology. The fracture-cave body is communicated by faults, showing a nearly circular or elliptical shape. Karst water mostly corrodes along faults to water leakage. (3) The paleo-channel karst system zone at the runoff karstic near the karst slope is developed, which is controlled by the changes of water table and the distribution of faults. The river channels are distributed in a dendritic multi-layered

pattern along NE and NEE directions, and the conditions of water collection and discharge are complex. (4) The faulted karst system develops in regions with robust fault activity, exhibiting a planar strip-like distribution and potential vertical development within diverse karst belts. Karst water primarily dissolves along structural fractures on both sides of the fault, giving rise to a V-shaped characteristic in the karst system.

MODELING HYDROCARBON SYSTEMS USING AN EXAMPLE SOUTH TORGAY SEDIMENTARY BASIN (KAZAKHSTAN)

Araibek ZHIYENGALIYEV[1]*, Atyrau Oil and Gas University named after Safi Utebayev (zhiengaliev_2000@mail.ru)
Dulat Azhgaliev[2], Atyrau Oil and Gas University named after Safi Utebayev

Abstract

In modern understanding, the hydrocarbon system represents a set of concepts: the area of genesis and accumulation of primary hydrocarbons, migration channels, time of entry and localization of mobile hydrocarbon fluids into oil and gas traps. New data on the South Torgay sedimentary basin (STB) in recent years shows and confirms the rift genesis of large structures of the second order: grabens-synclines and horsts-anticlines. There are 3 structural-formational complexes (SFC) in the section. The material composition of the SFC allows us to distinguish 3 stages of rifting, each of which reflects the accumulation and main stages of development of the STB: pre-rift (Upper Paleozoic), rift (Lower - Middle Jurassic) and epirift (Upper Jurassic - Lower Cretaceous).

Systematic analysis of basin data expands understanding and improves understanding of the conditions for the formation of the region. Researchers receive valuable information that has practical application, and the efficiency of studying local objects and deposits during exploration and development of hydrocarbon deposits is significantly increased.

The degree of knowledge of promising complexes: Upper Paleozoic deposits - quasi-platform complex (QPC), Jurassic complex of rift filling, platform complex of Upper Jurassic - Lower Cretaceous, decreases with depth. It is possible that separate hydrocarbon systems could exist for each complex. However, this is not certain!

These studies are devoted to a more detailed examination of the Upper Paleozoic deposits, the least studied part of the section, which is of significant practical interest.

- QPC deposits are characterized by pronounced sedimentary genesis, can contain significant volumes of hydrocarbon reserves, and serve as a reserve for planning regional production according to STB.
- Ideas on the model of formation of deposits in the Upper Paleozoic cause wide discussion among many researchers in this region. An important conclusion of recent years is the division of basement and upper Paleozoic deposits into two different strata.
- Oil and gas localizing objects in the Paleozoic stratum are characterized by a peculiar structure and localization, often confined to the protrusions of the foundation. In the thickness of the foundation, researchers identify a separate type of HC accumulations, which belong to the upper decompressed part – the "*weathering crust*" of the foundation.

The “origin” of hydrocarbon deposits in the Paleozoic finds an analogy with examples of known deposits in the basins of foreign countries. These are large deposits: “*White Tiger*”, “*Rona Ridge*”, “*Bongor*”, etc. These objects are characterized by different geological structures, but they are united by the presence of the main productive strata associated with Upper Paleozoic

deposits and huge potential for the implementation of broad comprehensive scientific research. Modeling of hydrocarbon systems based on geological-geochemical, thermobaric and numerical methods substantiates new opportunities for effective forecasting and assessment of the resource potential of the South Basin, taking into account the increasing trend of decreasing overall production in the region and the late stage of development of most fields in the Jurassic and Lower Cretaceous complex.

RIVER SCALE AND CHANNEL PATTERNS IN THE ROCK RECORD

Cristiano GALEAZZI[1]*, Seoul National University (cpgaleazzi@snu.ac.kr)
Renato ALMEIDA[2], Universidade de Sao Paulo

Abstract

The recognition of river scale and channel patterns in the geological record are assumed gaps in fluvial sedimentology. They are of great importance for regional palaeohydraulic and palaeogeographical reconstructions. Rivers in general have been subject of research for more than a century but the link between proposed classifications and the rock record has been problematic, with a persistent lack of effective criteria to distinguish among channel patterns in fossil fluvial systems. A compilation of modern alluvial rivers with available water discharge data at a global scale was undertaken to to quantify the natural variability of channel patterns at the global scale, explore what controls may influence their development, and investigate whether channel pattern information is preserved in the alluvial plains in order to develop tools for recognizing them in the sedimentary record. By surveying 361 reaches, we present a quantitative channel pattern classification based on sinuosity and channel count index applicable to the recognition in the rock record. A continuum of channel patterns ranging from high-sinuosity single channel to low-sinuosity multichannels is documented, along with their alluvial plains and their conditions of occurrence. Preserved barforms in the alluvial plains of these rivers are used to infer and quantify paleoflow directions at the channel-belt scale and result in ranges of paleocurrent circular variance that may lead to channel pattern identification in the rock record. Channel scale was investigated by comparison of high-resolution multibeam echo-sounding imaging of two reaches in the large Amazonas River and small rivers.High-resolution bathymetric maps of the Solimões-Amazonas River are presentend, along with the quantification of dune data from their riverbeds and riverbed samples. Dune morphology, height and leeside angles, as well as grain size, are related to water depth and these relationships are used to make inferences about how to identify large river in the rock record and are compared with interpreted large river deposits. The recognition of channel patterns and river scale may be used to predict paleogeographic features such as the scale of drainage basin area and discharge, slope, and annual discharge regimes.

Paleoweathering, Provenance and Tectonic Settings of Mesozoic Succession of Mundhan Dome (MD), Jhuran Formation, Kachchh, Western India: Insights from Petrography and Geochemistry

Poonam Rajeshbhai MANGTANI[1]*, Department of Geology, Faculty of Science, The M.S. University of Baroda, Vadodara, Gujarat, India (mangtanipoonam.geology@gmail.com)
Atul Vasant Joshi[2], Department of Geology, Faculty of Science, The M.S. University of Baroda, Vadodara, Gujarat, India

Abstract

The Mundhan dome (MD) in north western part of the Kachchh basin, Gujarat (GJ), comprises ~105 meters thick Upper Jurassic to Lower Cretaceous (Kimmeridgian to Hauterivian) siliciclastic succession belonging to middle, upper and Katesar members of Jhuran Formation. The middle member shows dominance of shales with subordinate siltstones, while the upper and Katesar members are marked by the presence of sandstones with varied primary sedimentary structures and fossil assemblages. In the present work, siliciclastic rocks of MD have been studied to understand their provenance and decipher the tectonic settings through petrography and geochemistry (major element oxides). The representative thin sections have been subjected to modal analysis carried out using Leica DM 2500 microscope. The framework grains show the dominance of quartz (monocrystalline, polycrystalline) with subordinate feldspars (orthoclase, microcline, plagioclase) and lithic fragments in a modal average ratio of Q83F12L5. The framework grains are embedded in siliceous matrix cemented by calcareous material and show tangential grain to grain contacts. As per Dott's classification, these sandstones have been classified as 'Quartz Arenites' and Sub-arkosic Arenites. High Qm /Qp ratio and dominance of K-feldspar over plagioclase feldspar indicate a stable cratonic source. The presence of orthoclase and microcline suggest plutonic igneous or metamorphic source. The preservation of fresh feldspar grains is due to quick burial and minimal transportation. The geochemical analysis carried out using Wavelength Dispersive – X-Ray Fluorescence (WD-XRF) at Sophisticated Instrumentation Centre for Applied Research and Testing, Anand, GJ, India-reflects high abundance of SiO2 and low abundance of Al2O3, Na2O, CaO and TiO2. The K2O/Na2O ratio > 1 as well as Al2O3/TiO2 ratio ~22, indicate deposition in passive margin setting and derivation from felsic rock source respectively. The deposition in a passive continental setting is substantiated by tectonic discriminant diagrams reflecting acidic igneous and metamorphic provenance. The average SiO2/ Al2O3 value > 5 is suggestive of the progressive maturity of sediments. The values of chemical index of alteration, chemical index of weathering and plagioclase index of alteration being suggest moderate to high chemical weathering and deposition in vicinity of source without extensive recycling. Thus, the research concludes that the rocks of Jhuran Formation are deposited in a marginal marine passive continental setting with acidic igneous and metamorphic provenance.

Depositional characteristics of a braided river-type alluvial fan controlled by a small syndepositional fault

mingyue LI[1]*, China University of Petroleum (East China) (3176637243@qq.com)
xianguo Zhang[2], China University of Petroleum(East China)

Abstract

Syndepositional fault, Braided river, Alluvial fan, Huanghua Depression, Kongdian Formation
A great deal of understanding has been achieved on the influence of large syndepositional faults at the basin margins on the type and spread of sedimentary systems within the basin, while the influence of small syndepositional faults within the basin on the sedimentary characteristics of alluvial fans has been less studied. In this study, a typical braided-river-type alluvial fan stratigraphy of the Paleocene in the Huanghua Depression, Bohai Bay Basin, China, is selected to recognize the influence of small syndepositional faults on braided-river deposition in the fan.
The study area was frequently fractured during the period of the Paleocene Kongdian Formation, and later on, it was under the joint control of dextral strike-slip stress, forming several small-scale syn-sedimentary normal faults. The differences in sedimentary characteristics between the two sides of the faults are identified using cores and logging, the paleogeomorphology of the two sides of the syndepositional faults is recovered by well seismic combination, the relationship between the syndepositional faults and the location, scale, and lithological assemblage of the fan and the braided channel development is analyzed from the temporal and spatial dimensions. It is found that hanging wall of the syndepositional fault has a large volume of space, sufficient sediment supply, and the development of a thick sand body with multiple stacking phases, which is characterized by part of the near-source and rapid accumulation; in the footwall of the syndepositional fault, the thickness of the sand body is relatively thin due to the influence of the paleogeomorphology; and the change of the activity of the syndepositional fault along the strike affects the direction of the braided channel and the degree of the deformation of the strata, which has formed the special pattern of the river channel sand body spreading. Using the above results, the sedimentary phase model in the alluvial fan under the control of small syndepositional faults in the faulted lake basin in the study area was established.

Paleoclimate evolution of the lower fourth sub-member of the Shahejie Formation in Niuzhuang Subsag during deposition

Rongkun LI[1]*, CHINA UNIVERSITY OF PETROLEUM (1308745376@qq.com)
Yingchang Cao[2], CHINA UNIVERSITY OF PETROLEUM
Yanzhong Wang[3], CHINA UNIVERSITY OF PETROLEUM

Abstract

Exploration practice has confirmed that the Paleogene red beds in Dongying Sag have great exploration potential. It is of great theoretical and practical significance to clarify the evolution of paleoclimate for revealing the control of extreme climate conditions on lake-basin sedimentary system and reconstructing paleogeography in this period.Several short-term thermal climate events such as PETM, ETM2, EECO and MECO occurred worldwide in the early Paleogene.Under the influence of thermal climate events, the red beds in the lower fourth sub-member of the Shahejie Formation of Niuzhuang Subsag developed and recorded the paleoclimate evolution process under the control of thermal climate events.In this paper, the red beds of the lower fourth sub-member of the Shahejie Formation in Niuzhuang Subsag are taken as the research object, and the paleoclimate evolution process is restored by statistics of natural gamma ray spectrometry data, analysis of climate information contained in tne analysis of fossil sporopollen assemblages and stratigraphic superimposition patterns.The results show that the climate of the lower fourth sub-member of the Shahejie Formation in Niuzhuang Subsag during the deposition period was characterized by overall drought, which can be divided into four stages. In the early stage, fluctuating humidity occurred, and then turned to dry and tended to be stable, and the temperature gradually decreased.

Depositional characteristics of Cretaceous carbonate tidal channels in southern Iraq

Zihao LIU[1]*, Research insititute of Petroleum and Expoloration of PetroChina (278433581@qq.com)
Zhenyong Xu[2], Research Institute of Petroleum ExplorationDevelopment, PetroChina
Rui Guo[3], Research Institute of Petroleum ExplorationDevelopment, PetroChina
Fengfeng Li[4], Research Institute of Petroleum ExplorationDevelopment, PetroChina

Abstract

The Cretaceous Mishrif Formation carbonate reservoir in southern Iraq is one of the most important oil-producing layers in the world, in which carbonate tidal channel sediments serve to develop the best reservoirs. Clarifying their characteristics and distribution is crucial for reservoir prediction and further development. An integrated analysis of modern sedimentation, cores, thin sections and log data shows that the tidal channels are widely distributed in the lagoon environment and can be divided into 3 sedimentary facies as channel, inter-channel, and point shoals. Grainstone, bioclastic packstone, and wackestone are the main rock types in the research area with good sorting and rounding, a large number of intersecting bedding, and upward-fining successions. Rudists and bivalves with large diameters can be observed in grainstones, indicating a high energy environment, while benthonic foraminifera, bivalves, and echinoderm are always found in packstones and wackestones with a high content of micrite. On the plane, the tidal channel sedimentation is interlaced and banded, while the point shoal sedimentation is sporadically distributed between distributary channels. Vertically, the sedimentation can be generally divided into three stages, presenting the characteristics of multiple overlapping tidal channels. Three types of tidal channel contact relationships can be recognized as overlapping, cutting, and isolating, of which the connectivity of cutting is the best and that of isolating is the worst. Based on quantitative statistics and sea level changes, it can be concluded that as the sea level rises, the available space increases and the width of the tidal channel gradually increases, but the curvature decreases. The planar distribution range of point shoals also decreases, but their thickness changes little, indicating that their development is not related to tidal channel sedimentation. However, as the distribution range of tidal channel sedimentation expands, more point shoals are transformed. This study can enrich the study of carbonate tidal channel sedimentology, and also provide insights into reservoir prediction and efficient development in similar regions.

Temporal and spatial variations in sediment provenance in the Gunsan Basin, Yellow Sea

JUNHYUK SEO[1]*, Department of Environment and Energy, Jeonbuk National University (signicher@naver.com)
HYOJONG LEE[2], Petroleum & Marine research division, Korea Institute of Geoscience and Mineral Resources (KIGAM)
SUNYOUNG PARK[3], Petroleum & Marine research division, Korea Institute of Geoscience and Mineral Resources (KIGAM)
INAH SEO[4], Department of Earth and Environmental Sciences, Jeonbuk National University

Abstract

The Gunsan Basin is part of the Northern South Yellow Sea Basin (NSYSB) and bordered by the Qianliyan Uplift and Shandong Peninsula to the northwest, the Central Uplift of NSYSB to the south, and the Korean Peninsula to the east. With its recognized potential as a reservoir for both hydrocarbon and carbon dioxide, the basin's internal structure has received extensive attention for several decades. Nevertheless, studies on the sedimentary provenance have not been attempted which play a critical role in evaluating reservoir quality and reconstructing the basin's developmental history. In this study, sediment provenance of the Gunsan Basin is examined based on the petrographic and mineralogic characteristics of five boreholes (KACHI-1, HAEMA-1, IIH-1XA, IIC-1X, and INGA-1) acquired from each sub-basin and uplift zone. Each borehole is subdivided into three seismic units (SU) in ascending stratigraphic order, namely SU-1, SU-2, SU-3, bounded by the widespread unconformities, ES-1 and ES-2, identified through previous seismic exploration of the basin. In each borehole, the lowermost SU-1 exhibits a notable contribution of plagioclase and lithic volcanic fragments in each borehole, while the specific types of lithic volcanics observed vary depending on the individual borehole. On the other hand, SU-2 and SU-3 show a similar composition across all boreholes, predominantly composed of quartz and K-feldspar, almost completely devoid of plagioclase. Such notable shift in sediment composition from SU-1 to SU-2 and SU-3 suggests a significant change in provenance across the ES-1. The spatially heterogeneous sediment composition of SU-1 suggests that the detritus comprising SU-1 were most likely sourced from the nearby geological features within the basin itself rather than being transported from large, external source. It is probable that the local highlands existed during the earliest stage of the basin opening, serving as the primary sources for the sedimentary materials of SU-1. In contrast, the regional-scale consistency in sediment provenance during the deposition of SU-2 and SU-3 is recognized, indicating a large external source. The petrography of SU-2 and SU-3 is similar to that of the Qianliyan Uplift among the geological highs surrounding the basin, making it the most probable source. Such large-scale coherence in sedimentary supply from a single source region was primarily resulted from the subsidence and flooding of the entire basin. The spatiotemporal changes in sediment provenance identified in the Gunsan Basin not only align well with the tectonic history proposed based on seismic exploration but also offer new insights into basin evolution.

Campanian-Maastrichtian Paleoenvironmental and Sequence Stratigraphic Dynamics in the Southern Bida sub-basin, Nigeria: Insights from Sedimentology and Microfossils Studies.

Tope Shade ALEGE[1]*, Federal University Lokoja, Nigeria (tope.alege@fulokoja.edu.ng)
Kingsley Uchendu[2], Federal University Lokoja, Nigeria

Abstract

This study provides valuable insights into the paleoenvironmental dynamics and sequence stratigraphy of the Campanian-Maastrichtian period in the Southern Bida sub-basin through sedimentological and microfossil analyses. The research uses a combination of field mapping and laboratory analyses, including sedimentological facies analysis, petrography, and microfossil investigations. The study identifies three distinct facies: conglomerate, sandstone, and siltstone-claystone facies, indicating a range of environments from alluvial to braided stream, channel bars, and shallow marine settings. The facies association shows a basinward decrease in the energy of deposition. Textural analysis reveals coarse to medium-grained sediments with variations in sorting, skewness, and kurtosis. The pebble morphometric results suggest an angular to subangular with a maximum projection sphericity index (MPSI), considered dominantly fluvial. A statistical linear discriminate function scatter plot highlights a fluvial-deltaic system characterised by braided stream to alluvial fan deposits with a pronounced tidal influence. Heavy mineral analysis shows the presence of opaque and non-opaque mineral suites, suggesting a transportation pathway from upland areas of the Basement Complex to the basin. Calculated ZTR indices indicate compositionally immature to sub-mature sediments from a proximal provenance. The study also reveals that sediments within the Patti Formation exhibited Acritachs in an exclusively terrestrial palynomorph assemblage, indicative of a shoreface environment.

The Patti sediments yielded marine species of dinoflagellates cysts, palynomorphs, and foraminifera test lining, implying a shallow marine depositional setting. Vertical facies sequences within the Lokoja Formation revealed the lowstand and highstand system tracts (LST and HST), suggesting a progradational stacking pattern in response to sea-level fall. The sediments of the Patti Formation indicated a transgressive system tract (TST) terminating at the maximum flooding surface (MFS). The overall stratigraphic profile of the Bida sub-basin displayed a symmetrical log signature suggestive of tidal reversals during transgressive-regressive episodes. This integrated study significantly advances our understanding of the complex depositional processes and paleoenvironmental conditions during the Campanian-Maastrichtian period in the Southern Bida basin.

Northward subduction-accretion of the Bangong-Nujiang Meso-Tethys Ocean, Tibetan Plateau

Yiming LIU[1]*, Institute of Geology, Chinese Academy of Geological Sciences (michael_yatmingliu@foxmail.com)
Qingguo Zhai[2], Institute of Geology, Chinese Academy of Geological Sciences
Yue Tang[3], Institute of Geology, Chinese Academy of Geological Sciences
Peiyuan Hu[4], Institute of Geology, Chinese Academy of Geological Sciences

Abstract

The subduction-accretion is widely recognized as a critical process associated with the evolution of the Meso-Tethys Ocean. The compositions, deformation and ages of accretionary complex that are preserved in mélange zone can reflect the nature of subduction. New petrologic, sediment composition, deformation and detrital zircon data from the Jurassic sedimentary units, as well as the geochronological and geochemical data of contemporary andesite and basalt interlayers reveal two magmatic arc systems of 196 Ma and 163-153 Ma. These sedimentary units constitute an Early Jurassic island arc and a Middle-Late Jurassic fore-arc trench-basin in response to the northward subduction of the Meso-Tethys Ocean. Detritus derivation from an Early Jurassic arc-ophiolite complex contains a 196 Ma intra-oceanic arc together with contributions from oceanic crust in early development of the basin. This is consistent with the basalts that derived from an enriched mantle source with negligible contribution from crust. In contrast, detritus derivation from a Middle-Late Jurassic arc-accretionary system reveals a mixed source of 163-153 Ma continental marginal arc, oceanic crust and north terranes. Furthermore, the 163-160 Ma high-Mg andesites originated from melting of sediments from a subducted slab, and the melts subsequently interacting with the overlying mantle wedge. The Late Jurassic high-Mg andesite interlayers in the accretionary complex, and the previous identified fore-arc basalt and boninite in the study area, are coincided with subduction initiation. They are obvious younger than the 196 Ma island arc, indicating a complex subduction evolution of the Meso-Tethys Ocean. Structural analysis shows that the Late Jurassic to Early Cretaceous deformation of the accretionary complex is dominated by north-dipping thrust faults and local tight folds. The deformation features combined with the magmatic arc and sedimentary units indicate a polarity of northward subduction. We infer that the accretionary complex may result from the southward transition of the northward subduction zone of the Bangong-Nujiang Meso-Tethyan Ocean.

Deep marine siliciclastic sedimentation in a mélange zone: an example from the Late Cretaceous Fayah Formation in Batain Mélange, Northeastern Oman

IFTIKHAR AHMED ABBASI[1]*, Sultan Qaboos University (iftikhar@squ.edu.om)
Jenan Attar[2], Sultan Qaboos University
Mohamed A.K. El Ghali[3], Sultan Qaboos University
Abdulrahman Al Harthi[4], Petroleum Development of Oman

Abstract

Objective/Scope: This paper describes the depositional setting of a deep marine siliciclastic sequence in a mélange zone, commonly known as the Batain mélange formed during the Late Cretaceous along the northeastern part of the Oman Mountains. The Batain mélange is comprised of Permian to Late Cretaceous stratigraphy in a tectonically deformed area between Ra's Al-Hadd and Ra's Jibsch. The Batain mélange in its uppermost part comprises an early Maastrichtian siliciclastic sequence belonging to the Fayah Formation.

Methods: A complete section of the Fayah Formation at its type locality was measured and described to understand the constituent lithofacies across the formation and interpret its depositional setting.

Results & Conclusions: The Fayah Formation in Jabal Fayah area is over one thousand meters thick comprising five distinct facies associations; namely, i) interbedded claystone and sandstone, ii) debris and mass-flow, iii) graded sandstone, iv) Conglomerate, and v) calcarenite lithofacies. These lithofacies are repeated many times in the section. The interbedded claystone and sandstone lithofacies is grayish-green in colour, comprising thick monotonous clay and siltstone sequences occasionally interbedded with gray and green fine to medium-grained sandstone possibly deposited by settling of pelagic clays out of suspension in deep marine settings. This sequence constitutes the bulk of the formation. The debris-flow lithofacies association is matrix supported chaotic mixture of clay and boulders of granite, limestone, and volcanic rocks, some of which are a meter in diameter, possibly derived from the nearby Jabal Ja'alan basement rocks. These sediments were deposited along the slope due to submarine slumping and sliding. The sandstone lithofacies association exhibits a fining and coarsening upward trend making tens of meters thick sequences in various parts of the formation. The waterscape structures are common along with occasional sandstone dykes and convolute bedding reflecting syn-sedimentary deformation under fluidized conditions. The lithofacies was deposited by the channel-levee complexes. The conglomerate lithofacies association is comprised of a series of interbedded coarsening upward grit to pebble size conglomerates containing granite, volcanic, carbonate, and chert clasts of a few mm to cm in diameter. The conglomerate lithofacies was deposited by high-energy channelized flow in a sub-aqueous setting. The calcarenite lithofacies constitutes the uppermost part of the formation comprising brecciated limestone. The lithofacies is interbedded with green colour claystone and sandstone. The lithofacies was deposited along the shelf margin. Based on the above-described lithofacies associations, especially the dominance of debris-flow units and

turbidites, most parts of the Fayah Formation are interpreted to be deposited under a sub-marine fan setting. The submarine fan system was active during the last stages of Tethys Ocean closure at the onset of Batain nappe.
Novel Information: This study will help in understating the deep marine depositional setting, especially in isolated deep marine basins associated with the mélange zone.

Proposal of new gravel shape indicator by the 3D principal component analysis of fluvial gravels and assessment of its accuracies in detecting the fluvial geomorphology

Tomoo YOKOYAMA[1]*, Waseda University (tomoo.yy2014@gmail.com)
Tohru Ohta[2], Faculty of Education and Integrated Arts & Sciences, Waseda University

Abstract

The shape of sedimentary grains, i.e., roundness and surface smoothness were acquired by the transportation histories and depositional environment that grains underwent. Therefore, the shape of sedimentary grains might record an information to reconstruct the transportation histories and depositional environment that grains underwent. Therefore, numerous studies had been pursued to quantify the shape of sedimentary grains. Among them, Suzuki et al. (2015) proposed two shape parameters to quantitatively evaluate grain shapes by utilizing elliptic Fourier and principal component analyses (EF-PCA), which can quantify macroscopic circularity (REF1) and microscopic smoothness (SEF) of grains. Suzuki et al. (2015) furthermore revealed that on the REF1-SEF cross plot, sand grains derived from glacial, fluvial, foreshore, and aeolian environments form distinct clusters, and therefore the depositional environment can be predicted by the two indices. However, the limitations of Suzuki et al. (2015) is that it is only a 2-dimensional assessment of grain shape. Giving these limitations, we aim to expand the applications of REF1 and SEF to gravels and further propose a new 3D shape index. In this study, 242 gravels sampled from 8 locations along the Kuzuryu River (Fukui Prefecture, Japan) were investigated. Each gravel was photographed from three directions to investigate 3D gravel shape. The outline images of gravels were automatically extracted using Canny edge detection based on the method of Mukaizato and Ohta (2020).

The results showed that SEF (surface smoothness) revealed a statistically significant correlation with the fluvial transportation distance, however REF1 (2D elongation) did not showed a meaningful correlation. Therefore, we can conclude that SEF (surface smoothness) is an adequate index to determine grain shape but the REF1 index (2D elongation) has a room for improvement. We attempt to solve this problem by calculating REF1 from a-b, a-c and b-c plane images and conduct principal component analysis to extract 3D shape indices. As a result, the principal component 1 (PC1) was an indicator of cubic- to bladed-shape of gravels, and the principal component 2 (PC2) determined the rod- to disk-shape of gravels. Thereby, a 3-dimentional quantifications of gravels can be described mathematically as if the grain is cubic- bladed- rod- to disk-shaped.

In summary, the present result suggests that the convectional SEF index measured in 2D is still appropriate as a measure of the surface smoothness, but REF1 needs an improvement and this study succeeded to expand the REF1 into the 3-dimetional index to determine cubic- bladed- rod- to disk-shaped sedimentary particle morphologies.

Geochemical and statistical evaluation of Late Jurassic to early Cretaceous sandstones in the Bredasdrop sub-basin: Compositional signatures and provenance lithologies

Mogammad Yaaseen HENDRICKS[1]*, The University of the Western Cape
(myhendricks@uwc.ac.za)
Tapas Kumar Chatterjee[2], The University of the Western Cape

Abstract

Southern Offshore basins of South Africa are well known as potential provinces of hydrocarbon exploration and production. The complex syn-rift architecture of the Bredasdrop sub-basin developed during the break-up of West Gondwana can have adverse effects on the distribution of sediments, especially for the exploration of hydrocarbons. This study aims to classify rocks based on their geochemical signature and shed light on compositional variations within a spatial and temporal context. Over several decades, the geochemical classification of rocks has been met with scrutiny but have not been dealt with in the correct context.

Thirty samples have been selected for geochemical analysis and have been analysed through XRF and ICP-MS devices. Geochemical classification of the early Cretaceous sediments in the Bredasdorp Sub-basin revealed a feldspatho-quartzose and litho-quartzose nature. Major element ratios identified diagenetically altered samples (High ratios of P2O5/Al2O3, CaO/Al2O3 and Fe2O3/Al2O3), especially those affected by poikilotopic calcite micro-nodules that can have detrimental effects on the CaO content. Nevertheless, these samples were removed in calculations and further statistical transformations. The CIA values ranged from 48.56-71.04 (indicating incipient to moderate weathering intensities) with an average of 59.41. Calculations of Land surface temperatures (showing values of 12°C and 14°C for the V-BUSM and BUSM-1AT1 respectively), indicates an increase stratigraphically possibly confirming the transition from Humid to Arid during the Berriasian to Valanginian Stages. This change is also confirmed by different weathering trends between the two successions.

Compositional data analysis using Principal Component Analysis (PCA) and Discriminant Function Analysis (DFA) revealed a spatial change in provenance with the northern part of the studied section receiving sediments from a collisional terrain such as the Cape fold belt (including the Table Mountain Group and Bokkeveld Group) whereas the southern sections received more sediments from the basement highs (recycled Malmesbury Group (and Pre-Cape sediments) and Cape granite suite). The major element data showed a tectonic setting to be of a rifted margin whereas trace element data (concentrated by multiple cycles of depositional histories) showed ‘false’ tectonic settings. Therefore, the use of trace element data and to some extent major element data should be re-evaluated in rifted settings and hence should not be used casually in studies for tectonic settings. The geochemical footprint of diagenesis and depositional environments should always be considered as part of the context before it is used blindly in evaluating tectonic setting identification.

Detrital zircon U-Pb geochronology and geochemistry of Carboniferous sedimentary rocks from the Kharkhorin terrane, Central Mongolia

Erdenechimeg DAVAAJAV[1]*, 1. Institute of Geology, Mongolian Academy of Sciences 2. Department of Geology and Geophysics, School of Arts and Sciences, National University of Mongolia (erdenechimegd@mas.ac.mn)
Oyunchimeg TUMEN-ULZII[2], Institute of Geology, Mongolian Academy of Sciences
Sharav DAVAANYAM[3], Institute of Geology, Mongolian Academy of Sciences

Abstract

The Kharkhorin terrane is located in the central part of the Khangay-Khentey orogenic system, dominated by the Carboniferous sedimentary rocks. We have conducted U-Pb geochronology and geochemistry analyses to determine the provenance, weathering conditions, and tectonic settings of sedimentary rocks from the Cuugel formation within the Kharkhorin terrane. The Cuugel formation mainly comprises a flysch sedimentary sequence consisting of bluish-gray, dark-gray siltstone, bluish-gray sandstone, and less conglomerate.

According to the whole-rock geochemistry analyses, the sandstones of the Cuugel formation have high Al2O3/TiO2 ratios (25.1 – 38.4), LREE/HREE ratios (LaN/YbN = 6.58 – 10.45), and negative Eu anomalies (Eu/Eu* = 0.64 – 0.97), indicate the felsic igneous source and deposited an active continental margin. All sandstones have low values for CIA (51.5 – 57.3), PIA (51.9 – 59.9), and ICV (0.86 – 1.03), suggesting the sandstones have undergone relatively weak weathering and have an immature source.

Detrital zircons from the bluish-gray sandstone (sample Kh-22-213) of the Cuugel formation range in size from 70 to 130 μm. Most zircons are euhedral prismatic, exhibit clear oscillatory and sector zoning in cathodoluminescence (CL) images, and have Th/U ratios greater than 0.1 (ranging from 0.25 to 1.28), indicating a primary source dominated by igneous rocks. All zircons yielded highly concordant zircon 206Pb/238U ages ranging from 801±19 to 331±9 Ma with four age populations identified at 801 – 770 Ma, 449 – 418 Ma, 403 – 362 Ma, and 356 – 331 Ma. The youngest peak of detrital zircons indicates the maximum depositional age of sedimentary rocks. The eight youngest zircon grains in this sample have a weighted mean age of 338.6 ± 3.3 Ma (MSWD = 1.1), which suggests that the sample deposited later than the Early Carboniferous age.

The sample contains zircon from two origins, magmatic and hydrothermal, identified by the rare earth element composition. Most zircons exhibit high (Sm/La)N values ranging from 14 to 400, a steep slope from La to Lu, strong positive Ce anomalies (Ce/Ce* = 33 – 252), and slightly negative Eu (Eu/Eu*=0.11–0.56) anomalies, indicating unaltered magmatic zircons. Hydrothermal-altered zircons can be identified by higher REE abundance, flatter LREE pattern (Sm/La)N ranging from 0.14 to 6.05, and minor positive Ce (Ce/Ce* = 1.1 – 6.8) and slightly negative Eu (Eu/Eu* = 0.13 – 0.56) anomalies. We used the provenance diagrams of U – Y and Yb/Sm – Y and the tectonic environment diagram of Th/U – Nb/Hf, suggesting detrital zircons in the studied sample were mainly derived granite–granodiorite–tonalitic rocks formed in arc-related/orogenic settings.

Preliminary study of the Jurassic Bansong Group in the Yeongwol area

Sang-eon PARK[1]*, Seoul National University (pse135@snu.ac.kr)
Jusun WOO[2], Seoul National University

Abstract

The Jurassic Bansong Group is an important key for understanding the tectonic regime of the Mesozoic Korean Peninsula. However, disagreement between biostratigraphic and U-Pb ages have caused confusion of interpreting time of deposition of the Bansong Group. To describe detailed lithofacies and interpret depositional environment, fieldwork to the group in the Yeongwol area has been conducted and resulted in two columnar sections from the Eorayeon and the Yeonhari sections. The Bansong Group in the study area can be roughly divided into lower conglomerate part and upper sandstone/siltstone alternation part. The lower part contains polymictic conglomerates which consist of well-rounded and poorly sorted pebble-to-boulder-grade clasts within the coarse-grained sand matrix, corresponding to the Sapyeongri Formation. Clast size decreases slightly upwards within succession, while ratio of the matrix increases. In the Jeongyang region, cataclastic conglomerate unconformably overlies the Joseon and Pyeongan supergroups. In the upper part, there is an alternation of fine to medium-grained gray sandstone and dark gray siltstone, which can be correlated to the Hyeoncheonri Formation, overlain by massive coarse sandstone, corresponding to the Deogcheonri Formation. In the Yeonhari section, erosional surfaces are observed at uppermost part of the Deogcheonri Formation. Ripples, cross bedding, and mud chips were identified in the sandstone layers, while leaf fossils and footprint-like structures were recognized in the bedding plane of siltstone layers. Cataclastic conglomerate in the Jeongyang section is estimated as the deformed lower part of the group. Polymictic conglomerates exhibiting wedge-shape bed and normal grading in the lower part can be interpreted as axial or hinterland fluvial system. Sandstone-black siltstone alternation with leaf fossils in the upper part may indicate lacustrine environment, and erosional surfaces can be an evidence for time of no deposition or erosion. Previous studies proposed the Bansong Group deposited in Early Jurassic syn-tectonic piggyback basin based on zircon age data and relationship with thrust fold. Distribution and lithology of the Bansong Group likely support this idea. Detailed facies analysis, together with our data, paleocurrents patterns and thin section petrography will provide to understand spatial distribution of the facies and integrated depositional history of the group.

Geochemistry and detrital zircon U-Pb geochronology of metasedimentary rocks of the Sergelen formation in Central Mongolia: Implications for their provenance and tectonic settings

Oyunchimeg TUMEN-ULZII[1]*, Institute of Geology, Mongolian Academy of Sciences (oyunchimegt@mas.ac.mn)
Erdenechimeg DAVAAJAV[2], 1. Institute of Geology, Mongolian Academy of Sciences 2. Department of Geology and Geophysics, School of Arts and Sciences, National University of Mongolia
Narantsetseg TSERENDASH[3], Institute of Geology, Mongolian Academy of Sciences

Abstract

This paper reports new results from U-Pb geochronological and whole-rock geochemical studies of metasedimentary rocks from the Sergelen formation in the Onon terrane, Khangay-Khentey Orogenic Belt, Central Mongolia, with the aim of constraining the depositional age, provenance, and the implication for tectonic setting. The Sergelen formation is mainly composed of quartz-sericite-feldspar schist, sericite-quartz schist, quartz-mica schist, black shale, and siliceous shale with minor amounts of quartzite, chert-quartzite, metavolcanic rocks, and limestone.

Totally, 136 detrital zircons from black shale (SKh-23-33) and siliceous shale (SKh-23-34) samples were subjected for U-Pb dating. The CL images show that detrital zircons from the two samples consist of euhedral to slightly subhedral, stubby to mid-long prismatic crystals (60-120 μm in length) with concentric oscillatory zoning and as well as with high Th/U ratios of 0.2 - 1.3, typically for igneous origin. Some of them are broken. Concordant analyses on the euhedral to subhedral zircon crystals from the black and siliceous shale samples give Early Neoproterozoic to Carboniferous 206Pb/238U ages between ~947 Ma and ~320 Ma and between ~654 Ma and ~315 Ma, respectively. However, their age clusters were similar, showing three major peaks at 428 Ma, 391 Ma, and 350 Ma. The weighted mean 206Pb/238U ages of the youngest detrital zircon population is 326.0 ± 3.1 Ma and 323.1 ± 2.6 Ma, respectively, for two samples, clearly indicating that their depositional age must be younger than Lower Carboniferous.

All metasedimentary rocks are classified as graywackes with minor lithic arenite. Geochemical features such as the ratios of SiO2/Al2O3 (3.22 – 8.15, av. 4.50), Al2O3/TiO2 (19.13 – 41.08, av. 25.01), LREE/HREE (4.84 – 14.77, av. 12.06), and Eu/Eu* (0.70 – 0.92, av. 0.82) values suggest that graywackes were mainly derived from the felsic igneous sources and fewer samples were sourced from intermediate igneous rocks. The meta-sedimentary rocks have a relatively low Chemical Index of Alteration (CIA; 49 to 61) and average Index of Compositional Variability (ICV) values of about 1.0, suggesting a mature source that has undergone weak chemical weathering.

STATE OF THE ART OF THE JUMA FORMATION, ALTO TAPAJÓS GROUP, AMAZONAS STATE, BRAZIL: STRATIGRAPHIC REMARKS AND ITS IMPACT ON THE STUDY OF THE ALTO TAPAJÓS BASIN

Pâmela Silveira Costa[1], University of Brasilia
João Gabriel Cavalcante Vieira[2], University of Brasília
Dermeval Aparecido Do Carmo[3], University of Brasília
Matheus Denezine[4], University of Brasília
Adriana Maria Coimbra Horbe[5], University of Brasília
Rodrigo Rodrigues ADORNO[6]*, Geological Survey of Brazil (rodrigo.adorno@sgb.gov.br)

Abstract

This study provides an overview of the stratigraphic understanding of the Alto Tapajós Group, with a specific focus on the Juma Formation, a lithostratigraphic unit of the Alto Tapajós basin. The Alto Tapajós basin is an intracratonic basin located in the Amazon area in Brazil, a globally significant biome for geodiversity. The Juma Formation, Alto Tapajós Group, has the potential to its stratigraphic record correlated with the Amazon basin due to its spatial proximity, but due to the scarcity of scientific studies, this correlation is merely suggested. In addition to its scientific significance, this lithostratigraphic unit holds economic importance as it yielded phosphate deposits, which are currently under exploration for their agromineral potential. Additionally, it presents an underexplored potential for hydrocarbons. In general, there is a notable scarcity of detailed geological studies on the Alto Tapajós basin, a gap that needs to be addressing to enhance the understanding its chrono-biostratigraphic evolution. Several proposals have been developed for the stratigraphy of the Alto Tapajós basin. However, the lack of detailed geological mapping in the region and the adjacent basement has has led to divergent interpretations regarding its chronostratigraphic scope. Six distinct stratigraphic frameworks have been published for this basin, and some of them with different designations for lithostratigraphic unities. This fact highlights the gaps in the stratigraphic knowledge of the Juma Formation, particularly in terms of biostratigraphy, with only one publication that assigns this unit to the Silurian-Devonian interval. Notably, the aforementioned publication assigned the studied section to a different stratigraphic unit, tentatively linking it to the Beneficente Group. Furthermore, considering the occurrences of Silurian-Devonian poorly preserved organic-walled microfossils, this interval was attributed to the Jatuarana Group and later to the Alto Tapajós Group. The present study opens a discussion about the stratigraphy of the Juma Formation conducted based on the study of three drill cores from the Alto Tapajós Group, situated on the right bank of the Jatuarana stream, Municipality of Apuí. This detailed analysis covers sedimentological, paleontological, and geochemical perspectives. Paleontological analyses of these three drill cores suggest a Precambrian chronostratigraphic interval, contrasting with previous suggestions of Silurian-Devonian. Therefore, the importance of revisiting the type-sections of all formations of Alto Tapajós Group is highlighted, providing precise geographical coordinates and detailed descriptions of its lithostratigraphic units. As final remarks, by comparing results from the studied areas with those from type-sections, a more

comprehensive scientific dataset will be used to correlate the Alto Tapajós basin with others, including the Amazonas basin, leading to a wider understanding of its geology and evolution.

Abstract

Genesis of ironstone is still a matter of debate in terms of iron source. Hydrothermal, terrestrial, and diagenetic Fe sources have been suggested for Proterozoic and Phanerozoic ironstones. In this study, we have investigated the uppermost Karri Formation of the Gangau Subgroup of the Paleoproterozoic Bijawar basin developed on the Budelkhand craton in India - a thin uneconomic sedimentary succession hosting ironstone with iron-rich stromatolites in an iron-rich clay matrix. The whole-rock composition of the ironstones shows more than 85 % Fe2O3+SiO2 content. Microscopic and SEM-EDS analysis reveals that hematite is the prominent iron-bearing mineral in the samples; however, goethite is also present in some samples, likely due to recent weathering. Oolites account for 60 to 70 % by volume. The relative enrichment of Th, Al, and Zr indicates detrital contribution to the matrix. Post Archean Australian Shale (PAAS)-normalized REE patterns of the samples display almost flat patterns with LREE enrichment compared to HREE, small positive Eu (1.21 to 2.0), and negative La, Gd, and Y anomalies, consistent with a seawater signal influenced by high-temperature hydrothermal fluids. Geochemical data and sedimentary features point to a mixed terrestrial and hydrothermal sources for the Karri Formation ironstone. Trace element and REE data further suggest a suboxic to anoxic deep-water basin redox with deposition of the ironstone at the redoxcline.

Abstract

The Charlie-Gibbs Fracture Zone (CGFZ) is the main transform system in the North Atlantic. It serves as a primary deep-water gateway for the current of the Iceland-Scotland Overflow Water (ISOW), which is part of the lower limb of the Atlantic Meridional Ocean Circulation that strongly modulates regional and global climate. The aim of this study is to determine the sedimentary processes in the area of a tectonically active deep-water gateway and to reconstruct the bottom current variability as reflected in the bottom sediments.

New geological and geophysical data were collected during the cruises of R/V Akademik Nikolaj Strakhov in 2020 and R/V Akademik Sergey Vavilov in 2021. The surveys included bathymetric studies using a deep-water multibeam sonar system, high-resolution subbottom profiling (2-6 kHz), and retrieval of two sediment cores using a gravity corer. Stratigraphic subdivision of the sediment cores is based on the micropaleontological analysis, ice-rafted debris (IRD) counts, calcium carbonate content and three radiometric 14C dates. Grain-size, bulk mineralogical, geochemical, and magnetic susceptibility analyses were used to distinguish lithological facies.

On the basis of the sub-bottom profiling, the current controlled sedimentation was inferred. Three types of local contourite drifts were identified in the valleys of the inactive fractures and the active transform: (1) channel-related drifts, (2) confined drifts, and (3) fault-controlled drifts. The ISOW current is the main agent controlling the drift formation in the northern valley. The influence of the Denmark Strait Overflow Water of northern origin and/or Low Deep Water of southern origin was also suggested for the southern valley. Tectonic deformations of the sedimentary strata have been detected within the valleys of the active and inactive transforms.

Studies of sediment cores have revealed of six sedimentary facies. During the Holocene, contourite sedimentation dominated with admixture of pelagic settling. The gradual increase of the ISOW current flow from the Late Pleistocene to the Middle Holocene was identified by the consistent disappearance of amphibole from the sediments. During the glacial intervals of the Late Pleistocene, the hemipelagic sedimentation with high input of ice-rafted debris prevailed in the fracture valleys. The acoustic stratification of the sediments is caused by the alternation of glacial

and interglacial intervals, at least in the upper part of the profiles. North Atlantic Ash Zone 1 layer, diatom ooze and turbidites were identified in the sediment cores, indicating short-term events.

Although the valleys of the CGFZ are well known as conduits for the ISOW flow, this is the first time that the contourite drifts have been revealed here. Therefore, our study highlights the importance of oceanic fracture zones in their role as deep-water gateways. They intensify the bottom currents that leave remarkable sedimentological imprints. Decoding these imprints helps to reconstruct the behaviour of the bottom current in the past and provides essential information for palaeoclimate reconstructions.

Abstract

Water exchange between the Baltic Sea (semi-enclosed brackish basin) and the North Sea began at about 8500 BP. Since that, dense (salty) North Sea water inflows spread in deep subbasins of the sea as contour currents and form contourite drifts. In a sense, these drifts are an accessible natural model of oceanic contourite drifts.

We identified and studied two drifts in the South-Eastern Baltic Sea, one in the Eastern Gotland Deep (“Gotland Drift”) and other in the Gdansk Deep (“Gdansk Drift”). For these purposes, a novel digital elevation model of the bottom relief and sub-bottom profiling data were used. Grain-size, organic matter and elements content were studied in sediment cores.

Complex Gotland Drift is located at the depth of 115-125 m and includes: channel-related contourite fan, elongated mounded detached drift, separated and sheeted drifts. The channel-related contourite fan originated first after start of North Sea waters inflow in the Baltic Sea (Littorina transgression). At the course of the weakening of the bottom currents the other types of drifts were forming. The numerous furrows (elongated pockmarks), originated from interaction of the gas seepages and bottom currents, complicate the surface of the Gotland Drift. The muddy contourites are laminated, sometimes micro-laminated, with high organic content and enrichment by hydrocarbon gases.

The Gdansk Drift is located at depths of 100-105 m, near the steep eastern slope of the Gdansk Deep, and consists of gentle mounded separated and sheeted parts. A 3-D geological model of the drift was constructed from subbottom profiling data. The model revealed structural depression in the Pre-Quaternary and overlaying limno-glacial sediments that conditioned location of the contourite channel. The drift, as well as Gotland Drift, was formed during the Littorina transgression.

Conturites indicate the shifts in the depositional environment of centennial time scales controlled by the North Sea water inflows and climate changes. Values of the ln (Zr/Rb) along the sedimentary sequences correlates well with the mean of organic-free sortable silt fraction ($\overline{(SS)}$), which is a well-known proxy for the bottom palaeocurrent velocity. Increased values of ln (Zr/Rb)

and $(SS)^{-}$ are inferred for the Holocene Climate Optimum, as well as a low content of organic matter in sediments. The weakening of the bottom currents began around 4000 BP, with marked decrease in velocity during the Little Ice Age.

Research was carried out with financial support from RSF, project No. 22-17-00170, https://rscf.ru/project/22-17-00170/.

Abstract

The Jimsar Depression and Shishugou Depression in the eastern part of the Junggar Basin are based on the Palaeozoic and have similar depositional setting. The main hydrocarbon layer of the Middle Permian in the southern Jimsar Depression, the Lucaogou Formation, is divided into the upper and lower members. The main hydrocarbon layer of the Middle Permian in the northern Shishugou Depression, the Pingdiquan Formation, is divided into the upper, middle, lower members. The depositional environments and stratigraphic correlations between the two formations are controversial, which significantly impacts the overall exploration deployment of the Junggar Basin, North China.

The rock exposure and drilling results of the Lucaogou Formation and the Pingdiquan Formation reveal that in the context of a salinized lake basin they are both grey black shale and dolomitic rocks deposited interactively, with overall similarity in the hydrocarbon source rocks and lithological sequences. It was found in the cores of the Lucaogou Formation and Pingdiquan Formation that the standard fossil Taoshuyuan Turfan Cod and fossilized sporoderm assemblages, and so on are basically the same. The stable presence of red beds in the overlying Triassic Leek Garden Formation. Combined, these studies consider the Lucaogou Formation is comparable to the Pingdiquan Formation.

Based on this, combined with seismic data, it was found that the Shaqi relief dividing the southern and northern depressions exists a part of underwater low relief. On this low relief, the Lucaogouo Formation in the south and the Pingdiquan Formation do not undergo a sedimentary break. Two exploratory wells were identified in the Jimsar Depression and the Shishugou Depression. After analyzing the characteristic biomarker compounds of the 206 sets of samples from the target layer

of the two wells and the 137 sets of XRD whole rock data, it was found that, the salinity of the water body in the Shishugou Depression in the north is lower than that in the Jimsar Depression in the south, but the fluctuations of salinity of the water body in both cases are similar to those in the palaeoenvironmental evolution. Based on the lithological sequence, flora and fauna community, seismic geological data, and parameters of characteristic biomarker compounds of the Lucaogou Formation and Pingdiquan Formation, the present study concludes that the lower and meddle members of the Pingdiquan Formation in the north and the Lucaogou Formation in the south belong to the same period of stabilization of undercompensated salinization lake basins. Although there are differences in paleo-salinity, and paleo-climate, they can be compared.

Sedimentological characteristics and surface microtextures of quartz grains in modern sediments of the Hantan River, South Korea

Soyoung BAEK[1]*, Kangwon National University (bbackso1019@kangwon.ac.kr)
Kyoung-nam Jo[2], Kangwon National University

Abstract

Surface microtextures in quartz grains (SMQs) analysis on laboratory experiments or modern sediments can provide immediate insight on transport processes and signature imprinted textures of specific depositional environments. In this study, we conducted a detailed investigation of SMQs within modern fluvial environments, including both the mainstream and its tributaries, considering the geological and geomorphological characteristics of the Hantan River in central South Korea. The comprehensive SMQ results in the Hantan River showed a dominance of mechanical microtextures, including angular to sub-angular outlines, various-scaled conchoidal fractures, steps, flat cleavage, v-shaped percussion cracks, and upturned plated. These findings indicate characteristics similar to high-energy fluvial environments, as sediments in the Hantan River are transported under significant hydrological energy during the rainy season, influenced by the monsoon climate which brings concentrated summer rainfall. In a detailed comparison of SMQs between the mainstream and its tributaries, the mainstream was characterized by more sub-angular outlines, small conchoidal fractures, v-shaped percussion cracks, and medium to high relief. In contrast, the tributaries showed prominent angular outlines, flat cleavage surfaces, and low relief. These difference of the SMQ between the mainstream and tributaries suggest relative distances differences from their provenance. This observation is further supported by the mineralogical composition that tributaries contain minerals from nearby parent rocks, while the mainstream includes minerals not only upstream composition minerals but also those from the tributaries after their confluence. Thus, the sediments in mainstream are expected to contain materials transported from more distant sources, suggesting they potentially originate from further upstream areas. Although understanding their specific sources requires further detailed study, the SMQ of the mainstream reflect increased abrasion and impacts resulting from the longer transport distance of the sediments compared to those in the tributaries. These findings on modern sediments can be applied to other fluvial sediments similar to the Hantan River and help in understanding the processes related to individual SMQ formation.

Source rock determination of detrital quartz grains by utilizing the Voigt peak separation of cathodoluminescence spectrum and fabric textures.

Naoya Miyashiro[1]*, Waseda University (naoyanomori@icloud.com)
Tohru OHTA[2], Waseda University

Abstract

Cathodoluminescence (CL) is a luminescence phenomenon that occurs when a rock sample is irradiated with an electron beam and the luminescence intensity, and its spectrum can variate due to the lattice defect and the amount of the impurity elements inherited in crystals. Therefore, CL spectrum of quartz may variate depending on the rock type, and thus, many previous studies have utilized the CL characteristics of quartz grains in order to conduct provenance analyses (e.g., Zinkernagel, 1978). However, most of these studies are based on the overall color and the shape of the CL spectrum, and few conducted isolation and extraction of the luminescence centers individually. In this study, we measured CL spectrum of quartz grains obtained from various igneous and metamorphic rocks, and attempted to propose a quantitative source rock determination diagram by using peak separation.

Sixteen rock samples, including volcanic, plutonic, high-temperature metamorphic, and high-pressure metamorphic rocks, were analyzed. The analysis was conducted using the scanning electron microscope equipped with the diffraction grating spectrometer. Using this equipment, CL spectrum between the wavelength band of 250-945 nm, covering the visible light region, was measured at 5 nm intervals.

The CL spectrum of quartz grains obtained from volcanic and metamorphic rocks commonly emit a bimodal light in the red region (around 420 nm) and the blue region (around 620 nm). Generally, the volcanic rock samples showed a stronger emission in the blue region, while the metamorphic rock samples showed a stronger emission in the red region. To further analyze these differences quantitatively, the obtained spectrum was separated into five peaks by using the Voigt function. The five luminescence centers are 1.60 eV (770 nm), 1.95 eV (620 nm), 2.80 eV (450 nm), 2.95 eV (420 nm), and 3.30 eV (380 nm), which are mainly due to lattice defect and impurity elements in crystals.

Principal component analysis was performed and grouped the relative emission intensities into (a) 1.60 eV + 2.95 eV + 3.30 eV, (b) 2.80 eV, and (c) 1.95 eV are indicators reflecting the effects of impurity elements, heat exposure, and pressure, respectively. Taking these into account, a ternary diagram with these components organized in three apexes was created.

In this diagram, volcanic rocks with significant emission intensity in the blue region and high-pressure metamorphic rocks with significant intensity in the red region are clearly separated. The

CL spectrum of the plutonic and the high-temperature metamorphic rocks are similarly discriminated. However, the difference were insignificant and plot regions of plutonic and the high-temperature metamorphic rocks showed a partly overlapping pattern.

In conclusion, it was shown that newly proposed diagram can be used to determine the source rock by restoring the impurity elements, the degree of heat exposure, and the degree of pressure in quartz grains, although further improvements are still needed.

Autogenic Oscillation of Grain-Size Transitions under Constant Sea-Level Rise-Flume experiment and Computational Modeling

Jaehyung LEE[1]*, Yonsei university (j_hyung_lee@yonsei.ac.kr)
Wonsuck Kim[2], Yonsei university

Abstract

The cause of formation in sedimentary structures can be broadly categorized into two processes: allogenic forcing and autogenic processes. Previous studies have often overlooked the influence of autogenic processes due to their small scale and randomness. However, recent studies (e.g., Kim et al., 2008) using flume experiments revealed that under calm environmental conditions, autogenic processes might cause cyclic signatures with measurable dimensions.

In this study, we analyze the periodic advancement and retreat of "grain-size transitions (GSTs)" under varying rates of sea-level rise. We conducted 33 experiments, with 11 different sea-level rise rates, repeated three times each. Under constant upper boundary conditions, the growth of the delta leads to the overall seaward advancement of the GST with occasional retreat. This repetitive advancement and retreat draw a zigzag-shaped trajectory, which can be quantified in two factors: the amplitude of GST movement and the frequency of retreat. Over 33 experiments, as the rate of sea-level rise increases, the amplitude of the trajectory decreases. However, the frequency of GST movement increases with a higher sea-level rise rate.

As sea level rises, more deposition occurs near the shoreline, leading to a decrease in the overall gradient of the delta surface. With the reduction in the overall gradient and the distance to the shoreline, the amount of sediment deposited on the delta surface decreases. As fluvial envelope (Powell et al., 2012) decreases, the storage and release of sediment, reflected by changes in gradient, occur more frequently for a given sediment supply rate. With the reduced amount of sediment stored during each storage phase, the amount of sediment to release decreases, resulting in shorter movement in GST.

To validate our experimental findings, we employed a simple one-dimensional delta model that incorporate the storage and release mechanism. The modeling results closely match the experimental results in the magnitude and frequency of GST movements. This study demonstrates the potential use of grain-size transition patterns driven by autogenic processes as a predictive tool for sea-level rise variations in limited and incomplete sedimentary records.

Geochemistry of Phosphatic Nodule within shale of Kopili Formation, Litang Valley, East Jaintia Hills, Meghalaya, India: Implications on Provenance

SHUBHAJIT KAR[1]*, GEOLOGICAL SURVEY OF INDIA (subhajit.kar@gsi.gov.in)
Rashmi Ranjan[2], GEOLOGICAL SURVEY OF INDIA
Dr. N Nandhagopal[3], GEOLOGICAL SURVEY OF INDIA

Abstract

An attempt is made to decipher the provenance of phosphatic nodule bearing shales of Kopili formations (Middle to Late Eocene) using geochemistry. The Kopili Formation comprises black splintery shales interbedded with marl and sandstone as its members, overlying the thick limestone unit of Upper Sylhet Limestone of Shella Formation, Jaintia Group, Litang Valley, Meghalaya, India. The area in and around Samasi-Pala-Larket-Akshe-Sherwang is found to have a concentration of phosphate nodules with varying size and shape within shale in lower part of the Kopili Formation. Phosphatic nodules ranging in size from a few mm to 10 cm have been observed within the lowermost shale unit occurring just above the contact zone, i.e. Marl of Kopili Formation and Upper Sylhet Limestone of the Shella Formation. The nodules are cherty and limonitic in nature. They are randomly scattered within the shale and have less concentration. The phosphate nodule bearing zone is discontinuous, and the nodules are sporadically distributed and confined to the lowermost shale horizon above the marl unit. These nodules vary from a few mm to 10 cm in size and are rounded, sub rounded, elongated, oval, or ellipsoidal in shape. The chemical composition of phosphate nodules (wt%): SiO_2 30.2 to 32.19%, Al_2O_3 10.33 to 11.3%, Fe_2O_3 14.9 to 17.04%, K_2O 1.1 to 1.3%, P_2O_5 varies from 5.23 to 19.18 % having an average phosphate concentration of 12.97 % in nodules only. The composition of shale varies from SiO_2 48.7 to 55.2%, Al_2O_3 19 to 20.84%, Fe_2O_3 7.75 to 14.33%, K_2O 2.11 to 2.88%. P_2O_5<1%. Using the Shapiro solution method, the presence of phosphate content is confirmed. The TiO_2/Zr ratio (avg. shale: 48.37; nodules: 44.86) represents that they have been derived from felsic, i.e. granitic to granodioritic sources. The phosphatic nodules are rich in La concentration. The average ratios Eu/Eu* (0.71) and Th/Sc (0.71) in shales also represent granitic to granodiorite sources. The lower to moderate ratio of Cr/V (avg. 0.61) & Y/Ni: 2.20 represents a probable derivation of source rocks from granitic terrain, but some amount of contribution from ultramafic sources can also be considered. The ratios of trace elements: Zr/Sc vs Th/Sc, represent two patterns regarding the source composition and effects on the source by sedimentation processes. The higher value of Zr in sediments is due to the association between detrital zircon and/or heavy minerals during sedimentation processes. The trace element variations such as La, Eu/Eu*, Th/Sc of shales and phosphate nodules also indicate that they were derived from the uplifted and eroded crystalline felsic terrain of granitic-granodioritic composition from the Himalayan ranges, with a likely contribution from the nearest orogeny such as Indo-Burmese and Naga hills. The REE patterns show the fractionated granitic rock at the source. The presence of phosphatic nodules reflects a warm climate to promote exuberant life, which is a pre-requisite for the accumulation of soluble

phosphate. It also indicates that the area was of shallow depth with slow accumulation, connectivity to the sea within the prevalence of stable paleogeographic conditions.

Geochemistry and petrography of Middle Jurassic Nariinsukhait sandstone: Implications for paleoclimate and provenance

Baigalmaa NOROV[1]*, National University of Mongolia (baigalmaa_n@num.edu.mn)
Erdenetsogt Bat-Orshikh[2], National University of Mongolia
Jargal Luvsanchultem[3], National University of Mongolia
Oyungerel Sodnom[4], National University of Mongolia

Abstract

The Nariinsukhait deposit, which has 1.2 billion tons of coal reserves, is situated in southern Mongolia. In 2020, more than 9 Mt coal was produced from the deposit. Middle and Upper Jurassic 34 sandstone core samples from exploration borehole were studied herein.

Petrographically, the sandstones are classified as fieldspatic litharenite and litharenite reflecting relatively weak weathering intensity in source area, probably due to arid or semiarid climate conditions. Provenance analysis indicates that the sandstones are sourced from transitional recycled orogen. Geochemistry of samples indicates that sandstones were derived from acidic and intermediate rocks and mixed with recycled older sedimentary rocks. Possible sources are volcanosedimentary rocks of Mississippian Tost Formation, granite and granodiorite of Early-Late Carboniferous Tavan-Uul complex and sedimentary rocks of Middle-Upper Triassic Noyon Formation. Paleoclimate indices (C-value, Rb/Sr, Sr/Ba, 1000xRb/K2O and CIA) reflect that coal seams were accumulated in warmer and more humid climate, when paleo-weathering was intense, whereas sandstones were deposited in relatively cold and arid climate. In Late Jurassic, it is more likely that paleoclimate became more arid and cold compared with Middle Jurassic, indicated by quite low CIA and Rb/Sr. Moreover, various discrimination diagrams suggested that Middle Jurassic coal-bearing sedimentary rocks were accumulated in foreland basin. It is consistent with previous interpretations of regional tectonic during Triassic and Jurassic time.

Retreat of the fan margin in an alluvial fan

Haein Shin[1]*, Department of Earth System Sciences, Yonsei University (hishin@yonsei.ac.kr)
Wonsuck KIM[2], Department of Earth System Sciences, Yonsei University

Abstract

This study employs two-dimensional modeling of the fan margin in an alluvial fan, under the constant upstream boundary conditions of sediment supply and water discharge and a steady base-level. The findings reveal an inevitable retreat after a period of progradation, attributed to temporal change in groundwater infiltration during fan development. Seven flume experiments, varying sediment and water discharge rates, were conducted to further investigate the effect of infiltration on the alluvial fan evolution and thus the occurrence of fan-margin retreat. Fans typically exhibit continuous progradation, but a critical point is observed at which the surface runoff fails to reach the fan margin, leading to sediment transport only limited to the channel tips. Consequently, the margin of the active fan surface retreats landward. From the apex to the retreating margin, all runoff water was presumed to penetrate the deposit, passing through the substrate. It is observed that the infiltration rate increases as the fan deposit becomes thicker (larger storage potential of the deposit as shown in the Holtan Equation). Notably, the experiment runs with higher Qs/Qw ratios develop thicker, steep-sloped fans, reaching the faster critical point for channels to drain all surface water to groundwater. Thus, the specific deposit thickness, controlled by the upstream boundary condition, serves as a trigger for the retreat process. This research sheds light on the complexities underlying autogenic fan evolution and provides a potential mechanism for fan-margin retreat without changes in external controls, e.g., tectonic processes.

Abstract

The Cretaceous sections of the Uppermost Hauterivian of the Umbria-Marche Basin (Italy Apennines) associated with the Faraoni Oceanic Anoxic Event (FOAE) were investigated. Deposits of this level in the region were first described by Cecca (Cecca et al., 1994).

In this study, a multi-methodological approach is undertaken combining microfacies, magnetic susceptibility and geochemichal techniques. Six sections were sampled for petrographic studies: Apecchiese road, Bosso, Burano, Frontone, Gorgo a Cerbara, Gubbio-Contessa. The aim of the study is to investigate the mineral and micropaleontological composition of the rocks, to identify microfacies that are the result of changing conditions of sedimentation before, during and after the FOAE. Samples were taken layer by layer at 5 cm intervals before, during and after the FOAE.

The rocks are represented by mudstones and wackestones. The bioclastic grains are mainly calcitized shells of radiolarians, less frequently foraminifers, ostracods, molluscans. Limestone textures are more often uniform indicating rather calm energetic conditions. Bioclastic lenses and or nodules could be the results of low-energy bottom-current and bioturbation features near the FOAE.

The percentage of radiolarians varies greatly throughout the analyzed stratigraphic interval and ranges from 1 to 12-15%. Based on the evaluation of the number of radiolarians, their size and diversity, as well as the presence of planktonic foraminifers, three microfacies are identified:

Microfacies 1 (MF1). Micritic mudstone with small, rare radiolarians, characteristic, as a rule, of remote deposits below and above the FOAE;

Microfacies 2 (MF2). Micritic mudstone to wackestone with rather large, diverse and frequent radiolarians, occurring near the FOAE at a distance of 50-60 cm before and after;

Microfacies 3 (MF3). Micritic wackestone with planktonic foraminifera associated with large and abundant radiolarians, characteristic of sediments inside the middle of the FOAE, as well as just before and after the FOAE at 5-10 cm.

The observed microfacies are consistent with published data, from studies of sections with the FOAE in the Apennines (Coccioni, 1998) and the Southern Alps (Cecca, 1996).

MF 2/3 are also characterized by the presence of detritus of thin-walled molluscan bivalves, single shells of small planktonic gastropods, ostracods, and fragments of ammonite shells (MF3), clumps of amorphous plant matter, palynofloras, scraps of plant detritus.

The general increase in bioproductivity, namely the abundance and flourishing of radiolarians, the appearance of heat-loving globigerina-like planktonic foraminifers identified as Gorbachikella

(Coccioni et al., 1998), the presence of other planktonic marine organisms and the terrestrial plant most likely indicate a rising surface water temperatures and increased influx of nutrients from eutrophic conditions established in the basin. Blooming of non-skeletal algae and oxygen depleted bottom-water conditions allowed the accumulation of enriched Corg black shales.
Correlating microfacies changes with fine detrital changes are planned with magnetic susceptibility data of the samples. MS variations associated with changes in the input of terrigenous clastic compounds from continental sources fluxes towards the marine area will confirm our assumptions about the increased flushing of organic matter from the land during the FOAE. Moreover, geochemical analyses are also planned to identify geochemical anomalies around the FOAE.

Temperature Effects on Ripple Migration and Bedload Transport Rates: Flume experiments

Sejin KIM[1]*, Yonsei University (mozaryong147@gmail.com)
Wonsuck KIM[2], Yonsei University
Yunhyeong LEE[3], Yonsei University

Abstract

In a fluvial environment, the complex interaction between fluid dynamics and sediment transport shapes the Earth's surface in response to sedimentary conditions e.g., climate. Particularly water temperature can affect depositional systems by changing the characteristics of fluid, such as viscosity. Even though water temperature affects not only the fluid itself, but also the interaction between fluid and sediment, which can lead significant morphological changes, there is limited knowledge in the temperature effects on morphodynamics. In this study we focus on the effect of water temperature on ripple migration rate and bedload transport rate. We use experimental data conducted under varying water temperature (between 10°C and 45°C) conditions. Using time-lapse images of the experiments and applying cross-correlation method to the topographic data, we could measure ripple migration rate. Ripple migration rates, coupled with different ripple heights under varying temperatures, enable the calculation of bedload transport rate. In the experiments, as water temperature increases, ripple migration rate increases, while ripple height decreases with increasing water temperature. Since the increase in the ripple migration rate has a more significant effect than the decrease in the ripple height with increasing water temperature, the bedload transport rate is expected to increase with increasing temperature.

This study contributes valuable insights into the intricate relationship between sediment transport through bedform migration and water temperature variation, and thus allows for better interpretation of paleo-climate in sedimentary records and prediction of landscape changes in different temperature regions.

Parvancorina :The anchor-shaped Ediacaran organism from Sonia Sandstone Formation of Marwar Supergroup, India

HUKMA RAM[1]*, Jai Narain Vyas University, Jodhpur, Rajasthan, India
(hukmaramchouhan@gmail.com)

Abstract

The present investigation documents and describes the anchor-shaped Ediacaran organisms assigned to *Parvancorina* on the sandstone bedding plane of Sonia Formation of Marwar Supergroup in India. This is the first report of *Parvancorina* organisms from India. Specimens are preserved as small, rounded to ovate, posterior shield-shaped impressions with an anterior-lateral widened portion and a posterior anchor-shaped structure. The Ediacaran period remains a captivating chapter in Earth's history, and within its fossil record lies the mysterious entity, *Parvancorina*. This abstract ventures into the depths of ancient oceans to illuminate the story of *Parvancorina*. This discovery adds a novel dimension to the understanding of *Parvancorina's* paleobiology and distribution, providing a crucial link to the broader Ediacaran biota in India and contributing valuable insights into the ecological dynamics of this enigmatic period in Earth's history. *P. minchami* shows both positive and negative relief preservation modes. In Sonia Formation, the recovered *P. minchami* specimens have been found in size ranges of 1.5 × 1.5 to 3.0 × 3.5 cm2 (length × width), suggesting preservation of adult and larger forms. The allure of *Parvancorina* lies not only in its peculiar morphology but also in the questions it raises about the evolutionary experimentation preceding the Cambrian explosion. Based on the *Parvancorina* and associated Ediacaran fossils assemblages, this study suggests in terrestrial to marginal marine habitats with moderate hydrodynamic forces.

Quantitative characterization of 3D pore structures and percolation characteristics in bioturbated reservoir media based on x-ray micro-CT: a case study of the neogene sanya formation in the Qiongdongnan basin, northern south China sea

Yongbin NIU[1]*, Henan Polytechnic University (niuyongbin@hpu.edu.cn)

Abstract

Organisms alter the primary texture of sediments, leading to alteration in petrophysical properties between the fills and host sediments, which affects reservoir properties and fluid flow characteristics . In this paper, the three plugs (S1, S2, and S3) selected were all derived from cores from the Sanya Formation in the Qiongdongnan Basin. The content of Ophiomorpha in the three selected plugs varied, with about 75% by volume of Ophiomorpha in the S1plug, about 60% by volume of Ophiomorpha in the S2 plug, and about 50% by volume of Ophiomorpha in the S3 plug. The 3D scanned data volume of the three selected plugs was obtained using the X-ray microscope (Zeiss Xradia 510 Versa) (XRM) to scan the rock plugs in the Key Laboratory of Paleomagnetic and Palaeotectonic Reconstruction, Institute of Geomechanics, Chinese Academy of Geological Sciences, and a 3D pore structure model was established. The geometric characteristics of the microscopic pore structure were quantitatively and visually characterized by a modified maximal ball algorithm, and connectivity analysis of the pore structure was carried out. Next, numerical simulations of the percolation characteristics of the analyzed bioturbated reservoir samples were performed using digital core software (Avizo) and multi-physics field simulation software (Comsol). The results show that: (i) 3D pore structures reveal that pore volume, pore area, pore equivalent radius, throat area, throat equivalent radius and throat length have a large distribution range; among them, the pore volume has the largest distribution range, which can vary by 6 orders of magnitude, indicating that the pore size distribution of the bioturbated reservoir is uneven and has strong heterogeneous characteristics; (ii) the connected pore structure is very complex , and as the equivalent radius of connected pore increases, the coordination number also gradually increases, the better the connectivity, Finally, numerical percolation simulation results also suggested that larger connected pore space plays a key role in the effective permeability of the reservoir. This study has important implications for analyzing the modification effect of bioturbation on oil and gas reservoirs and enhancing production and recovery in the study area.

Identification characteristics of barrier sandstones of Benxi Formation in Ganquan-Fuxian area in the Ordos Basin China

Renhai PU[1]*, Depart of GeologyNorthwest University (purenhai@nwu.edu.cn)
Xiangzheng MENG[2], Shaanxi Yanchang Petroleum (Group) Co., Ltd. Oil and Gas Exploration Company

Abstract

Barrier sandbar is the main reservoir microfacies of Benxi formation gas reservoir in Ganquan Fuxian area. However, due to the lack of exact insight into its diagnostic characteristics, the well location deployment lack of basis significantly. Based on logging, core and thin section data, the vertical and horizontal distribution, depositional cycle, logging facies analyzed for the barrier sandstones of Benxi Formation in Ganquan-Fuxian area. The results show that Benxi Formation in Ganquan-Fuxian developed two longshore barrier sandbars in NNW orientation, overlapping on the bilateral slopes of a paleomorgraphic highland. Barrier sandstones are beaded thickening, with maximum sandstone content up to about 50 %, and maximum single sandstone thickness 22m. The barrier is generally 3-10 km wide and more than 40 km long, simultaneously with the sedimentary characteristics of tidal channels and shoreface shoals. Sandbodies consist of pebbles and coarse to fine sandstone with herringbone cross bedding, tabular cross bedding, low angle cross bedding and subparallel bedding, graded bedding and biological disturbance. Two kinds of depositional cycles exist in the barrier depositions. One is an upward finning, the other is the upward coarsing. The former cycle is more common. There are four types of logging facies in barrier sandstone: box type, funnel type, bell type, and serrated type. The barrier sandstones are of high overall compositional maturity, medium textural maturity with locally lower or higher. The center of the barrier has good petrophysical properties for high-yield gas wells.

4University of Mines and Technology, Faculty of Geosciences and Environmental Studies, Department of Geological Engineering, P.O. Box 237, Tarkwa-Ghana.

Abstract
This study investigated the origin, source area, and tectonic environments of sandstones of the Tarkwaian Group, which are part of the Paleoproterozoic formation situated in the northeastern region of the Ashanti Belt in Ghana.
An integrated approach involving petrography and geochemistry was used to achieve the research goal. A total of twenty-five (25) sandstone samples were carefully selected and their modal mineral composition was examined using the Leica DM750P polarizing microscope.
Additionally, geochemical analysis of major, trace, and rare earth elements was performed on all 25 sandstone samples using the ICP-AES and ICP-MS techniques. The observed minerals in the studied sandstones include quartz (monocrystalline and polycrystalline), muscovite, opaque minerals, possibly iron oxides, serecites, and plagioclase feldspars. Quartz was the most abundant component, constituting an average of 87.8% of the framework composition. Feldspars

(plagioclase) accounted for approximately 5.5% of the total framework grains, while sedimentary lithic fragments made up an average of 6.7% of the total framework grains. The average composition of the major oxides suggests that they are more enriched in SiO2 (84.9%), Al2O3 (8.3%), and Fe2O3 (2.7%) than other oxides. This indicates that the sandstones are predominantly composed of quartz and are thus, quartz arenites. Compared to the Post-Archean Australian Shale (PAAS) values, the sandstones exhibited a general depletion in major oxides, except for SiO2, Al2O3, and K2O, which were enriched relative to the PAAS. The high values of SiO2/Al2O3 (average: 12.74) and relatively moderate values of K2O/NaO (average: 1.42) suggest that the sediments are compositionally mature. The sandstones displayed a moderate concentration of Zr (average: 135.96 ppm), indicating zircon depletion and thus suggesting sedimentary sorting. The sandstones also showed moderate values of light rare earth elements (LREE) with an average LaN/SmN ratio of 1.38, and heavy rare earth elements (HREE) with an average LaN/YbN ratio of 6.97, as well as a negative Eu anomaly with an average Eu/Eu* ratio of 0.87. These findings are consistent with the Th/Sc against Zr/Sc plots. The high Chemical Index of Alteration (CIA) signature (average: 76.79 wt%), Plagioclase Index of Alteration (PIA) values (average: 90.13 wt%), and Index of Compositional Variability (ICV) (average: 0.61 wt%) suggest intense chemical weathering in the source area. Overall, the mineralogical and geochemical characteristics of the sandstones indicate that they were likely deposited in a passive continental domain or within intra-cratonic terranes.

The Sedimentary Characteristics of the Braided River Delta of the Triassic Lower Oil Group in the Block 9 area of the Tahe Oilfield

zhao lei[1]*, sinopec (zhaolei.syky@sinopec.com)
Duan Tai Zhong[2], sinopec

Abstract

The understanding of the sedimentary environment in the Triassic Lower Oil Group of the No.9 area in Tahe Oilfield varies between scholars. By core observation, thin section identification, grain size analysis and log, the sedimentary facies is considered to be the braided river delta as a whole, and the main subfacies are braided river delta plain and braided river delta front. The lithology of the target layer is dominated by sandstone and from the bottom up the grain size becomes finer. The lower part is mainly coarse sandstone, medium sandstone, which is the braided river delta plain subfacies, including braided distributary channel, distributary interchannel and natural levee. The upper part is a large section of fine sandstone, siltstone, which is the braided river delta front subfacies, including underwater distributary channel, underwater distributary interchannel and mouth bar. The braided river delta sedimentary model in the study area is summarized. It is a regressive sedimentary process where the base level rises and the lake deepens. In the low water level period of the lake, the braided distributary channel sediments extend to the center of the basin, and the braided river delta plain is mainly developed, while the braided river delta river front is smaller in scale. When the lake level rises and transforms the low-level deposits, the braided river delta front is mainly developed, forming the braided river delta “small plain, large front” sedimentary characteristics. The property of sand is good, which forms a favorable place for oil and gas accumulation in the study area.

Three dimensional distribution characteristics of physical property with sedimentary depth in the Ulleung Basin of the East Sea: based on downhole logging data

Gil Young KIM[1]*, KIGAM (gykim@kigam.re.kr)
Kiju Park[2], KIGAM
Bo Yeon Yi[3], KIGAM
Dong Geon Yoo[4], KIGAM
Gwang Soo Lee[5], KIGAM

Abstract

The physical property data (downhole log data) were collected from logging-while-drilling (LWD) operations conducted in the Ulleung Basin of the East Sea, in 2007 and 2010. LWD was conducted using Schlumberger logging tools (GeoVision for resistivity, SonicVision for velocity, Telescope for data transmitting, and Ecoscope for porosity and density). Three-dimensional distributions of physical properties (density, porosity, velocity, electrical resistivity) for the sediments in the Ulleung Basin have been processed and displayed. The 3D distribution maps are categorized according to regular burial depth (from seafloor to10 m, 10-50 m, 50-100 m, 100-150 m, 150-200 m, 200-250 m below seafloor). Overall, the distribution characteristics of physical properties largely reflect the lithological features, incorporating various analyses from drilled core samples. Furthermore, density and velocity generally increase with sedimentary depth, while, porosity decreases. High resistivity values are observed within depth intervals of 50-100 m. Notably, intervals bearing gas hydrates, as identified through seismic data and drilling cores, exhibit elevated velocity and resistivity, significantly influencing the distribution characteristics of physical properties. This study provides vital insights into the physical properties concerning sedimentary depth in the Ulleung Basin, serving as essential information for future investigation in the area. The 3D distribution map of physical properties stands as a valuable resource for diverse prospective studies within the Ulleung Basin region.

Characteristics of Mesozoic Reservoirs in Gaoqing Region

Xiaolong CHEN[1]*, China University of PetroleumEast China (2697870403@qq.com)
Liqiang Zhang[2], 13280371131
Yiming Yan[3], 13280371131

Abstract

The truncation unconformity exists between the Mesozoic and the Paleoge-ne and the Guantao formation in Qingcheng uplift, and the denudation lines are distributed NW-EW. From the stratigraphic comparison diagram, the reservoirs are well developed, largely distributed in the plane, and overlapping vertically.

The strata in the south are thin and the thickness of the reservoirs is small. With the increase of the strata thickness to the north, the thickness of the reservoirs shows an increasing trend.

Based on the comprehensive analysis of previous studies, through core observation and thin section analysis, the use of pore structure analysis technology, petrological characteristics analysis technology, combined with geophysical data such as well logging and earthquake, the study of the characteristics of lithology, characteristics of diagenesis and reservoir space of the Mesozoic reservoirs in Gaoqing Region is carried out. The following conclusions are drawn:

(1)Reservoir lithology is sandstone, siltstone, pebbly sandstone and basalt; oil-bearing lithology is mainly siltstone, with a small amount of medium sandstone and fine sandstone and pebbly sandstone.

(2)Development of volcanic rocks in the Xiwa formation, with less stratum outcropping and sedimentation of sandstone and mudstone interbeds. The Mengyin formation is mainly sedimentary facies and delta facies, mainly massive thick sandstone mixed with mudstone. The Santai formation is mainly sedimentary facies and delta plain sediments, mainly purple-red mudstone in the upper and bottom, gray mudstone in the middle and lower parts, occasionally mixed with thin sandstone.

(3)After the Mesozoic deposition in Gaoqing Region, the Cenozoic did not experience deep burial(maximum buried depth<2500m),the buried depth is shallow, the compaction and pressure solution are weak, the degree of development of feldspar and siliceous cementation is not high, the carbonate cementation is mainly calcite cementation, a small amount of iron calcite, the dissolution of carbonate cement is strong.

(4)Pore types in Gaoqing Region are rich, the reservoir space is mainly primary pores, and intercrystalline pores and feldspar dissolved pores are also seen. The proportion of primary pores surface pore rate is greater than 60% under the microscope. The primary pores in medium and coarse sandstone are the best reservoir space, these pores generally have good connectivity, large pores, few impurity bases in the pores, and have good reservoir capacity; the reservoir space of medium and fine sandstone is mainly secondary pores, mainly for the dissolution of feldspar and debris, mainly caused by the dissolution of meteoric fresh water.

Sedimentary Characteristics and Controlling Factors of Biogenic Limestone in the Middle Part of the First Member of the Shahejie Formation, Shanghe area, Huimin Sag

Yu HU[1]*, National Key Laboratory of Deep Oil and Gas, China University of Petroleum (East China) (2410186320@qq.com)
Jian Wang[2], National Key Laboratory of Deep Oil and Gas, China University of Petroleum (East China)

Abstract

The middle part of the first member of the Shahejie formation (Es1z) in the Shanghe area of Huimin sag belongs to the low exploration layer. Currently, high-yield oil and gas have been encountered in the biogenic limestone of the first member of the Shahejie formation. However, the depositional model and distribution characteristics of biogenic limestone in this area are unclear, which restricts its oil and gas exploration. Based on the theories of sequence stratigraphy, seismic sedimentology, and modern sedimentology, combined with core, logging, and seismic data, this article establishes a sequence stratigraphic framework for the Shahejie formation in the Shanghe area, clarifies the sedimentary characteristics and controlling factors of biogenic limestone, and establishes a sedimentary model for biogenic limestone. Research suggests that the Es1z is a lacustrine intrusion system tract, which can be divided into five fifth order sequences; Vertically, biogenic limestone mainly develops at the top of the third fifth order sequence, and horizontally, it mainly develops in the underwater uplift area in the central northern part of the study area; The distribution of biogenic limestone is controlled by periodic lake level changes, volcanic activity, geomorphology, and hydrodynamic conditions; Based on control factors, a development model of biogenic limestone is established. As the water in the lake basin gradually deepens, the energy gradually weakens, creating a favorable environment for the survival of organisms in the middle stage of the lake intrusion system tract. Meanwhile, the low uplift formed by volcanic activity in the early stage of the first member of the Shahejie formation provides a large amount of nutrients, leading to the extensive development of biogenic limestone during this period.

Effect of floodplain morphodynamics on channel avulsion: Outcrop observations of the Cretaceous Tando and Namyang basins in the mid-western part of the Korean Peninsula

Kyungjin LEE[1]*, Kyungpook National University (kyungjin@knu.ac.kr)
Yong Sik Gihm[2], Kyungpook National University

Abstract

Channel avulsion controls the spatio-temporal variations of alluvial successions, and the combined effects of trunk channel-bed aggradation and contrasting sedimentation rates between the proximal and distal floodplains create the cross-floodplain topographic gradient, providing necessary conditions for channel avulsion. Well-exposed alluvial successions of the Tando and Namyang basins in the mid-western part of the Korean Peninsula were studied to unravel the effects of floodplain sedimentation on channel avulsion. These alluvial successions are classified into four facies associations (FA-1: gravel-bed stream, FA-2: floodplain fines, FA-3: crevasse channel, and FA-4: crevasse splay). Below the overlying, avulsed gravel-bed stream deposits (FA-1), the underlying overbank deposits (FA-2, FA-3, and FA-4) exhibit the following changes in depositional features. First, the stacked beds of overbank deposits show vertical facies variations from floodplain fines (FA-2) to compensational and/or progradational stacking crevasse channel (FA-3) and splay (FA-4) deposits. Second, the mean values of ten maximum clast size in crevasse channel deposits (FA-3) show coarsening-upward trends with systematic paleoflow directions identical to the overlying, avulsed gravel-bed stream deposits (FA-1). Deposition of crevasse channel and splay deposits rapidly filled with accommodation space close to the trunk channel, and these spatial changes in sedimentation rates created the cross-floodplain topographic gradient. The coarsening-upward trends with systematic paleoflow directions suggest that the increased gradient led the overbank floodwaters to advance toward the distal floodplains. As a result of the continuous sedimentation of the crevasse channel and splay deposits, the trunk channel bed was perched above the distal floodplains, and the associated gradient advantage provided favorable conditions for channel avulsion. Thus, the overbank sedimentation plays an important role in the floodplain morphodynamics, and thereby causes channel avulsion.

Characteristics of Mesozoic reservoir development in Gubei Sag

hongwei RANG[1]*, ranghongwei@outlook.com (ranghongwei@outlook.com)
Liqiang Zhang[2], 2556248893@qq.com
Yiming Yan[3], 2556248893@qq.com

Abstract

Gubei Sag is located in the north of the Gudao bulge in Zhanhua Sag, Jiyang Depression. The Xiwa, Mengyin, Santai and Fangzi formations developed in the Mesozoic in Gubei area. The Xiwa Formation is mainly interbedded with volcanic rocks, mudstone and siltstone, with poor clastic rock properties. Mengyin Formation sandstone reservoir is a relatively high quality reservoir in the study area. Taking Gubei 107 well as an example, it mainly develops interlayers of sandstone and mudstone, and the medium and fine sandstone reservoir with better oil content is Mengyin Formation. Sand-conglomerate and mudstone interlayers of varying thickness are mainly developed in Santai Formation and Fangzi Formation, and the reservoir quality is poor.

The clastic rocks in the study area develop facies types such as alluvial fan, braided river delta and shoreline shallow lake. Alluvial fan deposits mainly develop fan root subfacies and fan end subfacies. The braided river delta facies mainly develop delta plain subfacies and front subfacies. The main rock types of clastic rock reservoir in this area are lithic feldspar sandstone and feldspar lithic sandstone, followed by lithic sandstone and feldspar sandstone. The quartz content in sandstone is low, generally in 40%-60%. The average content of feldspar is between 10% and 25%, and the average content of cuttings is generally between 12% and 30%.

The reservoir space of sandstone reservoir in the study area can be divided into intergranular dissolved pores, intragranular dissolved pores, mold pores, authigenic mineral dissolved pores and various fractures. Intergranular pore is the main reservoir space of effective reservoir. The sand body of Mengyin Formation in the study area has strong compaction, mainly medium and strong compaction. Compaction and porosity reduction are the key factors for the densification of Mesozoic clastic rock reservoir in the study area. The cementation mainly occurred in the early and middle diagenetic stage, and carbonate and siliceous cementation reduced the pore space of the reservoir, which is an important factor for reservoir densification in the study area. The content of feldspar and soluble minerals in this area is high, and the distribution of solution pores is common, which is a favorable reservoir space for Mesozoic reservoirs in this area. The fractures produced by fracture include structural fractures, dissolution fractures, diagenetic contraction fractures, crushing fractures, etc.

On the whole, the clastic rocks of Xiwa Formation in Gubei area are mainly argillaceous sandstone with undeveloped pores. The reservoir space of the high-quality Mengyin Formation is mainly the medium and fine sandstone with little miscella, and the primary pores are the main reservoir space. The sandstone with high miscella content and poorly sorted pebbly sandstone of Mengyin Formation have few pores, and the reservoir space is mainly the secondary pores. The pebbly sandstones of Santai and Fangzi formations have high shaliness content, and the reservoir

space is not developed.

EPHEMERAL DEPOSITIONAL SETTING OF THE RED SANDSTONE IN THE SONIA FORMATION OF MARWAR SUPERGROUP, INDIA

PRAKASH BABU LAL[1]*, Jai narain vyas university (psaran162@gmail.com)
PAWAN KUMAR[2], Jai Narain Vyas University
ANSHUL HARSH[3], Jai Narain Vyas University

Abstract

The ephemeral depositional setting of the red sandstone within the Sonia Sandstone of the Marwar Supergroup in India presents a significant geological context for understanding ancient terrestrial environments. This study investigates the sedimentological characteristics, paleoenvironmental indicators, and depositional processes of the red sandstone units to elucidate the paleoenvironmental conditions prevailing during their formation. Field observations coupled with petrographic analysis reveal distinct sedimentary features such as cross-bedding, ripple marks, and mudcracks, suggestive of deposition in an arid to semi-arid environment intermittently influenced by ephemeral fluvial processes. Previous geochemical analyses, including elemental composition and stable isotopic signatures, provide further insights into the provenance, weathering history, and diagenetic evolution of the red sandstone. The presence of iron oxides and clay minerals within the sedimentary matrix underscores episodes of oxidation and pedogenesis, indicating fluctuating moisture conditions and periodic exposure to subaerial environments. Additionally, the identification of evaporite minerals and desiccation cracks within certain horizons points towards episodic drying and evaporation events in shallow lacustrine or playa settings. Integration of sedimentological, petrographic, and geochemical data enables the reconstruction of the paleoenvironmental dynamics during the deposition of the Sonia Sandstone. The observed features suggest a dynamic landscape characterized by ephemeral fluvial channels, interdune lakes, and seasonal variations in water availability. These findings contribute to our understanding of paleoclimatic conditions, landscape evolution, and sedimentary processes operating in arid settings during the Neoproterozoic era, offering valuable insights into the depositional history of the Marwar Supergroup in India.

Christian WINTER[11], University of Kiel, Germany

Abstract

The Magdalena River Delta (MRD) and the Aguja Canyon represent the most important geomorphological features offshore of northern Colombia in the Caribbean Sea. The Magdalena River, the largest river in Colombia, is considered the main source of fresh water and sediments into the Caribbean Sea. Thus, the sediment input directly influences the Magdalena Canyon architecture. The Aguja Canyon is a predominantly tectonic feature located north of the Sierra Nevada de Santa Marta which constitutes the highest coastal relief on Earth with an average elevation of ca. 4 km to an abyssal plain ca. 3.5 km deep in the Caribbean Sea.

No significant modern rivers flow into this canyon, which extends for ca. 115 km. Both complex canyon systems act as conduits, channeling sediments from the continent across the continental shelf into the abyssal plain.

Here, we report new data from both the offshore MRD and the Aguja canyon on detrital zircon U-Pb geochronology and trace elements from ten (out of 39) samples collected from box-cores near-shore to deep-water environments (~50 to ~4000 m deep). The sampling took place during a research expedition aboard the German Research Vessel Maria S. Merian (November 2022). Particle sediment size distributions of the box-cores show no significant sorting in distance to the coast, and turbidite depositional sequences suggest event-based downslope transport.

We analyzed 1100 detrital zircon grains by LA-ICP-MS for U-Pb ages and trace elements to constrain their provenance. In the MRD, the zircon grains yield concordant and nearly concordant U-Pb ages ranging from 0.1 to 2620 Ma, whereas in La Aguja Canyon, the ages range from 46 to 1798 Ma. The size of most zircon grains is larger than 100 μm in both the MRD and La Aguja Canyon, irrespective of the distance to the coast. Similarly, the morphology of the grains varied from equant and elongated grains to broken grains with rounded terminations. The zircon grains exhibit varied responses under CL (Cathodoluminescence), many show oscillatory or linear zoning typically of magmatic zircons, while others show core and rim features typical of metamorphic grains and another proportion of zircon grains do not show any response under CL.

The youngest age clusters in the MRD at about 0.1 to 8 Ma, 75 Ma, 155 Ma, and 275 Ma, denote provenance from the Central Cordillera of Colombia. The ages from 459-682 Ma suggest main provenance from the Santander Massif/San Lucas Range, while the age range from 916 to 2232 Ma (largest peak at 991 Ma) suggests provenance from the Eastern Cordillera. On the other hand, the youngest age peak in the Aguja Canyon (50 Ma) reflects provenance from the Santa Marta Batholith, a Paleogene intrusive suite of the Santa Marta massif. Additional significant age peaks at 186 and 265 Ma, denote provenance from the gneisses and meta-sediments intruded by the batholith. Older clusters in the range 434-534 Ma and 998 to 1765 Ma (main peak at 998 Ma) denote provenance from the Santa Marta and San Lorenzo Schist, both intruded by the Santa Marta Batholith.

A high-resolution sequence stratigraphic framework of the Mississipian coastal system of the Poti Formation, Parnaíba basin, Brazil

Ricardo Guimarães PAIVA[1], Parnaiba Iron Consulting
Matheus DENEZINE[2]*, University of Brasília (matheusdenezine@gmail.com)
Carolina ZABINI[3], University of Campinas
Carlos Emanoel SOUZA CRUZ[4], University of Brasília

Abstract

This work studied the siliciclastic rocks of the upper portion of the Canindé Group, dated to the Mississippian by palynomorphs, represented by the Longá and Poti formations, as well as the lower portion of the Balsas Group from the Pennsylvanian Epoch, characterized by the Piauí Formation. The Parnaíba basin, located in the northeastern part of the South American platform, is intracratonic and developed within Western Gondwana, with a maximum thickness of 3500 m in its deepest sections, comprising Paleozoic to Mesozoic sedimentary and intrusive/extrusive igneous rocks. The focus of this study is on the Mississippian Poti Formation, representing a coastal system shaped by terrestrial, marine, and atmospheric processes, resulting in various depositional environments. Thirteen sedimentary facies within the upper Longá, Poti, and lower Piauí formations were identified and grouped into eight facies associations: Storm-dominated shallow-marine deposits offshore (FA1) and shoreface (FA2). Tidally-dominated coastal deposits, including tidal sand-ridges (FA3), protected tidal deltas (FA4), distributary estuarine channels (FA5), and tidal flats (FA6). Alluvial deposits, comprising fluvial channels (FA7) and overbanks (FA8). FA1-2 predominantly consist of fine to very fine sandstones with hummocky/swaley cross-stratification and grey bioturbated mudstones and shales, indicating shallow marine deposits. FA3-6 are characterized by medium to very fine sandstones with sigmoidal, trough, planar cross-stratifications, climbing ripples, mud couplets, interbedded with silty shales, representing coastal deltaic to estuarine tidally dominated deposits. FA7-8 are represented by conglomerates and sandstones with large planar to trough cross-stratifications, interpreted as alluvial deposits. Eight high-frequency sequences were established, including one in the gradual contact of Longá/Poti formations (LP), six within the Poti Formation (I to VI), and one in the basal portion of the Piauí Formation (Pi). LP sequence shows incomplete deposition with observed FA1 in the transgressive system tract (TST) and FA2 in the highstand system tract (HST). Poti's I to III sequences are characterized by lowstand systems tracts (LST) FA2 as incised shorefaces, TST retrograding offshore bars (FA1) and HST prograding shorefaces (FA2). In sequences IV to VI occurs the maximum development of a tidal dominated coastal system, were the LST is represented by FA7 as infills of incised valleys, with the TST represented by FA3, FA5 or FA6 and HST by FA2 and FA4 deposits. Pi sequence is incomplete, with an erosive sequence boundary and LST alluvial deposits (FA7 and FA8). This stratigraphic framework, were, a complex coastal system, tidally influenced, is developed in Poti Formation time, gives a high-resolution model that can be used to prospect economic resources, such reservoirs of natural gas as the incised valleys alluvial infills in

sequences IV to VI, or to coal prospect as the IV to VI TST tidal flats, were it should preserve better organic matter. Besides such applications this model invites the continuity of research such as high-resolution biostratigraphy, geochronology and allostratigraphy of the Paleozoic Parnaíba basin.

Distribution and environment changes of sand ridges on the southern shelf of Korea

Eun-Je JEONG[1]*, Korea Institute of Geoscience and Mineral resources (ejjeong513@kigam.re.kr)
Gwang-Soo LEE[2], Korea Institute of Geoscience and Mineral resources
Jong-Hwa CHUN[3], Korea Institute of Geoscience and Mineral resources
Jang-Jun BAHK[4], Chungnam National University

Abstract

The sand ridges on the southern shelf of Korea, parallel to the shoreline, are well preserved on the mid-shelf. The sediments of the sand ridges in the study area primarily originated from the paleo-Seomjin River and were redistributed during the post-glacial sea-level changes. Through analysis of sediment properties and vertical variation of sedimentary facies using deep core sediment from these sand ridges, we reveal the evolution of depositional environments on the southern mid-shelf of Korea during the post-glacial period. The core sediment data indicate the gradual transition of sand ridges from terrestrial to marine environments in response to the sea-level rise. The core sediments indicate interbedding of mud and sand facies with abundant shell fragments deposited during periods of lower sea-level, and the deposition of thick homogeneous sand facies since the rise in sea-level. These thick sand layers, exceeding 15 meters in thickness, observed in the upper core sediments, indicate that they were deposited under high-energy environments. This study demonstrates that the environmental changes and development of sand ridges on the southern shelf of Korea are closely associated with sediment supply, oceanographic regimes, and the post-glacial sea-level changes. Additionally, we used the seismic data to determine the distribution and thickness of sand ridges on the southern shelf of Korea.

Stratigraphic and sedimentological study on the Pohang Basin, SE Korea

TAEYEON KIM[1]*, KIGAM (tykim@kigam.re.kr)
YOOJIN KWON[2], KIOST
SUJI CHOI[3], Samoo Architects & Engineers
GEESOO KONG[4], KIGAM
YIKYUN KWON[5], KONGJU NATIONAL UNIVERSITY

Abstract

The Pohang Basin emerged as a pull-apart basin resultant from crustal extension during the Early Oligocene, coinciding with the back-arc opening of the East Sea. This geological phenomenon influenced the eastern coast of the Korean Peninsula during the Late Oligocene. Diverging from the conventional characteristics of pull-apart basins, the Pohang Basin underwent diagonal extension during its inception, resulting in a distinctive fan-shaped evolution. Its sedimentary composition predominantly comprises nonmarine siliciclastic and deep-marine sediments, with terrestrial sediment influx originating from two distinct directions. During the initial phase of basin development in the early Miocene, sediment deposition primarily transpired from the southern periphery, subsequently transitioning towards the western sector. These shifts mirror regional tectonic dynamics that significantly shape the basin's evolution. Employing seismic and deep-drilled core data, this research endeavors to elucidate the basin's evolution and depositional chronology. Seismic analysis delineates the sedimentary succession into seven discernible units based on their acoustic properties. Complementary drilling core analysis identifies thirteen sedimentary facies, further categorized into five facies associations. Time structure and isopach maps prove instrumental in discerning sediment sources, revealing predominant sediment transport from the south and west. This study contributes to a more comprehensive comprehension of the Pohang Basin's evolutionary trajectory and sedimentary interpretation, thereby facilitating enhanced Neotectonic and stratigraphic investigations in the East Sea region.

Building the GIS of International Quaternary Map of Europe and Adjacent Areas (IQUAME2500): Connecting and Harmonising the European Quaternary Geology without Political Boundaries

Kristine E.C. ASCH[1]*, Federal Institute for Geosciences and Natural Resources (BGR)
(Kristine.Asch@bgr.de)

Abstract

The project of the International Quaternary Map of Europe and Adjacent Areas (IQUAME 2500) is a multinational cross-boundary project and international collaboration with research organisations and national geological surveys in Europe is essential. Scientist from more than 40 countries are participating and a scientific board of Quaternary researchers ensures the scientific quality of the resulting GIS map layers.

The project is coordinated by the Federal Institute for Geosciences and Natural Resources (BGR) under the auspices of the CGMW (Commission of the Geological Map of the Word, Sub-Commission Europe) and with support of INQUA, the International Union for Quaternary Research.

The first edition of the map (BGR and UNESCO, 1967 – 1995) was published as paper map series in 14 map sheets, the new “map” edition is developed as a spatial data base within a geoinformation system and will be available on-line, in several layers, at the BGR Geoportal (https://geoportal.bgr.de)). It will represent the distribution of Quaternary deposits across the entire European continent, on-shore and off-shore. Within the IQUAME project BGR compiles centrally the spatial data information in cooperation with the project participants and uses actual publications, maps and additional, available project results.

The following features are being collected and compiled:
• lithology and geochronological age of Quaternary units,
• genetic descriptions of the units
• maximum extent of the ice sheets
• directions of ice movement
• extent of Arctic sea ice
• postglacial rebound
• off-shore Quaternary information (in cooperation with the EU EMODnet Geology project).
• active faults
• extent of permafrost,
• key localities (e.g. geologically and anthropologically interesting sites)

As multinational cross-boundary project, international collaboration with research organisations

and national geological surveys in Europe is essential. Scientists from more than 40 countries are participating and a scientific board of Quaternary researchers ensures the scientific quality of the resulting map layers.

The participation of numerous international partners presents a challenge and requires interoperability and data harmonization in respect to semantics, structure and geometry. To achieve this aim, common standards and guidelines needed to be developed and applied by all participants: structured vocabularies to describe the IQUAME's contents, a common topographic base, technical procedures to include the map data and technical guidelines to aid the partners to submit their data.

Apart from the participants' contributions, the IQUAME project includes results from actual publications, map and projects results, so that a synthesis of the current status of European Quaternary geological mapping and research will be created.

The presentation will show the background and process of building the GIS of the IQUAME, outline it's challenges and present the new status of the map layers.

Exploring Neotectonics and Seismicity during the late Quaternary in the vicinity of Gish fault in Darjeeling-Sikkim Himalaya through PGRS, MEQ, DGPS and OSL dating

RITU Pragya CHOURASIA[1]*, Geological Survey of India (ritu.chourasia@gsi.gov.in)
Anita Singh[2], Geological Survey of India
Deepanjan Ghose[3], Geological Survey of India
Anita Kumari[4], Geological Survey of India
Vishal C Kharkongar[5], Geological Survey of India
Niva Brahma[6], Geological Survey of India
Ashishit Lakra[7], Geological Survey of India
Imti kumzuk[8], Geological Survey of India
W S Rocky[9], Geological Survey of India
Mohammad Atif Raza[10], Geological Survey of India

Abstract

The Darjeeling-Sikkim Himalaya and its foredeep basin have active transverse faults linked to earthquakes, including the NE-SW trending Gish fault. Previous research lacked detailed knowledge of the Gish fault. Photo Geological and Remote Sensing (PGRS) studies, (Micro Earth Quake (MEQ), Differential Global Positioning System (DGPS) studies and Geological Mapping (GM) on a 1:25000 scale were conducted to explore its neotectonic, dynamics, dimensions, and seismicity.

PGRS studies revealed evidence of neotectonic in the Gish basin, supported by active morphometric indices. MEQ studies confirmed left-lateral strike-slip faulting with multiple reactivations. The fault delimited the eastern Siwalik Group extension, exposing Quaternary alluvial fan deposits. DGPS studies showed that maximum shear stress aligns parallel to the Gish Transverse Fault, shedding light on its behaviour and significant geological role in the region. GM unveils that the Gondwana rocks on the Gish fault's eastern side shifted northward, thrusting below Daling phyllites (MBT/Ramgarh thrust), suggesting a left-lateral disposition. Geomorphic evidence in the form of the sharp bend of Lethi River from the northwestward side towards the southeastward side with tilted terraces, entrenched river system, triangular facets and seismites in the form of convolute bedding, sand dykes, flame structure, sagged clay horizon and synthetic faults in Quaternary deposits are also observed in the area.

Optically Stimulated Luminescence (OSL) dating of the older T3 terrace of Baikunthapur Formation in Gish River shows aggradation in the valley since 38 ± 2 ka and shows intermittent reactivation. Whereas Soft Sediment Deformed (SSD) structures in the form of convolute bedding in cm scale yield a depositional age of 2.7 ± 0.2 ka which is underlain and overlain by the undeformed sand deposit of 4.0 ± 0.2 ka 2.4 ± 0.2 ka respectively indicate neotectonic activity or earthquake event around 2.7 ± 0.2 ka years ago. Moreover, the field evidence of the Gish fault suggests its extension from Mazing town to the Teesta lineament, trending NE-SW, perpendicular to the major thrust (MBT/Ramgarh thrust) in the Himalayas. It may function as a tear fault, bearing geological significance.

A comprehensive assessment of the Gish fault's potential for future seismic events is vital. However, implementing preparedness measures and raising public awareness about safe practices can enhance resilience and reduce seismic risks in the region.

Abstract

During the retreat of the Laurentide lce Sheet (LIS) margin, the Gulf of St. Lawrence formed a large calving bay dominated by a high influx of glacial ice, meltwater and sediment through rapid ice flow. The retreat history of the LIS margin remains poorly documented in this region of northeastern North America, mostly because its morphosedimentary record lies on the seafloor. Recent mapping of glacial sediment-landform assemblages using swath bathymetry and terrestrial LiDAR reveal new information on the late-glacial and deglacial history of the LIS by the observation of (1) mega-scale glacial lineations (MSGLs) associated with the St. Lawrence lce Stream; and (2) series of grounding-zone wedges (GZWs), morainal banks and ice-contact submarine fans extending laterally along the shelf and the coastal zone. These ice marginal landforms and deposits record episodic phases of retreat of the marine-based LIS margin following its rapid retreat in the deeper waters of the Laurentian Channel –a deep submarine valley extending from the mouth of the Saguenay Fjord to the continental slope– after 14.8 cal ka BP. The occurrence of GZWs along distinct isobaths indicates that bathymetry exerted a strong control on ice stabilization during deglaciation by reducing the relative water depth at the ice margin and thereby the buoyancy and rate of iceberg calving, but ice-marginal re-advances over some GZWs suggest an additional response to climate-driven forcing. Following these events, the LIS margin retreated rapidly to the coastal zone slopes of the Québec-North-Shore, where a bedrock escarpment promoted a phase of very rapid ice flow that carved swarms of large glacial grooves distributed discontinuously over >500 km. As the LIS margin reached stages of stabilization further upslope during which it transited from a marine to a terrestrial base, submarine fans aggraded to form sandur-deltas by the delivery of large volumes of sediments and a rapid glacio-isostatically induced forced regression.

Reconstructing the glacial lakes of northern Quebec and Labrador (Canada) through field-based mapping and GIS modeling

Martin ROY[1]*, University of Quebec at Montreal (roy.martin@uqam.ca)
Hugo Dubé-Loubert[2], Ministry of Natural Resources and Forestry, Quebec
Etienne Brouard[3], Geological Survey of Canada
Arianne Vallée[4], University of Quebec at Montreal
Joerg M. Schaefer[5], Lamont-Doherty Earth Observatory, Columbia University

Abstract

The retreat of the Laurentide ice sheet in northern Quebec and Labrador (Canada) was accompanied by the development of at least 8 large ice-dammed lakes that left a spectacular record of raised shorelines, deltas, and outburst flood deposits in extensive river valleys flowing into Ungava Bay. Although the Ungava glacial lakes drained into the nearby Labrador Sea – an important component of the Atlantic Meridional Overturning Circulation, assessing the impact of these meltwater discharges on the ocean-climate system is prevented by the lack of data on the configuration and volume of these ice-dammed lakes. This situation reflects sparse mapping coverage in the region and the concomitant lack of constraints on the evolution of the retreating ice margin that controlled lake development and drainage pathways. Here, we reconstruct the areal extent and history of the main glacial lakes in northern Quebec and Labrador through remote mapping of raised shorelines and deltas on high-resolution satellite imagery, combined with field investigations that allowed elevation measurements of key strandline sequences. The pattern of ice withdrawal was documented though systematic mapping of the main deglacial landforms (eskers, moraines, meltwater channels). The chronology of lake development and drainage was constrained through Terrestrial Cosmogenic Nuclide (10Be) dating of shorelines and outburst flood landforms. The different results were used to reconstruct the areal extent of the lakes and calculate their volumes through a GIS-based approach integrating the paleotopography (glacio-isostatic deformation) and available ice-margin chronologies. Results provide reliable estimates of the meltwater volumes and show that the largest meltwater discharges came from glacial Lake Naskapi and nearby ice-dammed lakes located southeast of Ungava Bay. The 10Be ages indicate that the Ungava glacial lakes formed and drained over a narrow time interval of the deglaciation, which suggests that these meltwater discharges likely contributed to the main freshwater forcing that caused the 8.2-ka cold event. This work refines the sources of meltwater discharges of the last deglaciation, while highlighting the importance of field-based mapping in detailing temporal changes in former continental ice cover and attendant glacial lakes. Overall, these reconstructions improve the accuracy of paleogeographic reconstructions, which provide critical constraints for several fundamental and applied fields of Quaternary science.

Jure Atanackov[6], Geological Survey of Slovenia
Miloš BAVEC[7]*, Geological Survey of Slovenia (milos.bavec@geo-zs.si)
Petra Gostinčar[8], Geological Survey of Slovenia

Abstract

Reliable reconstructions of former ice sheets depend on geomorphological evidence, chronological data and suitable ice sheet models. A great amount of glacial geomorphological evidence exists for the European Alps and Dinaric Mountains. For the area covered by Slovenia and its surroundings, however, there is a lack of a compilation of all previously published information and its comprehensive review. In addition, chronological information is scarce and scattered across many publications. In this study, we systematically compile the information published so far to provide a better basis for modelling ice masses and to enable a robust investigation for future studies on the European Alps and Dinaric Mountains. We have compiled an inventory of previously mapped glacial landforms and other glacially relevant data from the literature, which is available as a database and presented in a web map viewer. In addition, we have created a modified version of the dataset that includes both modified raw data and new data collected by the authors of this study. The main focus of the database/web map viewer is on the glacial landforms formed during the last glacial cycle and their sedimentological description, age and internal composition. The landforms included in the database are available in three types of layers (polygon, line and point), depending on the shape and extent of the feature and the way it is represented in the literature. Other layers in the database are outcrop (point), geochronology (point) and geophysics (line). The data stored in the GIS database is available in ESRI geodatabase and shapefile format. Both the GIS database and the web map viewer are freely accessible.

This work was funded by the Slovenian Research and Innovation Agency as part of the project J1-2479, “Past climate change and glaciation at the Alps-Dinarides junction project”.

[Keynote] Biostratigraphical data to unravel and map the early Middle Pleistocene

Thijs VAN KOLFSCHOTEN[1]*, Leiden University, Faculty of Archaeology
(t.van.kolfschoten@arch.leidenuniv.nl)

Abstract

The early Middle Pleistocene, spanning the period between the Brunhes-Matuyama boundary and the base of the Elsterian/Anglian/Oka/MIS 12, covers several glacial/interglacial cycles and is hence complex. The early Middle Pleistocene geological record in Western Europe is, however, fragmented and long sequences covering at least part of the early Middle Pleistocene are scarce. An exception is the exposure of a long sequence of Quaternary deposits at Kärlich (Neuwied Basin, Central Rhineland, Germany). The deposits yielded vertebrate remains as well as early Middle Pleistocene Palaeolithic artefacts. Several stratified faunas, within which the *Mimomys* – *Arvicola* transition occurs, have been collected from the Pleistocene sequence (Kärlich main section - Kä A - H) exposed in the Kärlich pit. The older faunas Kä C - E are characterised by the presence of two *Mimomys* species, *Mimomys savini* and the smaller *Mimomys* cf. *pusillus*, Kä F yielded only *Mimomys savini*. The oldest representatives of the water vole *Arvicola terrestris cantiana* are recovered in the extensive fauna Kä G. Based on palaeomagnetic data and the heavy mineral associations, it can be concluded that the Kärlich main section correlates with the late Early Pleistocene (Kä A and Kä Ba) and the early Middle Pleistocene (Kä Bb - Kä G). The stratigraphical position of Kä H is still unclear.
The fauna Kä C with e.g. *Microtus* (*Stenocranius*) *gregalis* indicates an open environment and continental climatic conditions. The composition of the Kä E faunal assemblages is characterized by the occurrence of *Dicrostonyx* sp. in Kä E, indicative for an open environment and cool, glacial climatic conditions, next to *Clethrionomys glareolus* and *Apodemus* sp, indicative for a more wooded environment and more temperate conditions. The presence of *Dicrostonyx* and *Spermophilus* in the fauna Kä F indicates an open environment; *Dicrostonyx* cold climatic conditions. *Clethrionomys* sp. points to the occurrence of at least locally forested areas. The composition of the Kä G assemblage indicates an environment with bodies of water, forested areas, most probably along the beds of the river and areas with steppe vegetation outside the river valley. The relatively high percentage of *Clethrionomys glareolus* and *Apodemus sylvaticus*/*Apodemus maastrichtiensis* and the occurrence of *Eliomys quercinus* point to interglacial, or at least interstadial, climatical conditions during deposition of Kärlich G. The faunal record from Kä H is relatively poor.

Evolution of Middle Ganga Alluvium In Parts of Ghaghara Sub- Basin, India Gajendra Nath Dwivedi* and Subodh Kr. Sharma**. Lucknow and Nagpur

Gajendra Nath Dwivedi[1]*, Geological survey of India (Retd.) (gajendragsi@gmail.com)
Subodh Kumar Sharma[2], Geological survey of India (Retd.)

Abstract

ABSTRACT
Evolution of Middle Ganga Alluvium In Parts of Ghaghara Sub- Basin, India
Gajendra Nath Dwivedi* and Subodh Kr. Sharma**.
Lucknow and Nagpur

Ganga alluvium is one of the largest alluvial plains of the world formed due to sediments deposited in a foredeep located to the South of rising Himalaya. Though the major part of this thick sedimentary sequence is concealed, it preserves all signatures of the Mid to late Pleistocene period encompassing to the Holocene episodes.

The upper few metres of the sequence available along the cliffs may be studied directly while the major chunk of this huge pile of riverine sediments can only be interpreted on the basis of data available through limited drill holes drilled for specific purposes other than for stratigraphic interest and by indirect geophysical studies in certain patches for sub-surface structures.

The study carried out in parts of Ghaghara sub- basin of Ganga basin situated in Middle Ganga Plains clearly suggests that the sequence is broadly divisible in two parts viz. Ganga older alluvium dated more than 11.5 ka and the Ganga newer alluvium dated less than 11.5 ka to present. The Ganga older alluvium situated on a higher elevation is a polycyclic sequence of oxidised, yellowish, sand, silt and clay with calcrete (kankar) concretions /nodules and horizons while the younger alluvium situated on the river floodplains consists of greyish sand, silt and clay characterised generally by absence of calcrete concretions. The calcrete horizons are of great significance for reconstructing the palaeo climate and palaeo -geography.

A detailed study of landforms, variation in the litho packages, tectonic and climatic changes clearly indicate weaker summer monsoon precipitation during glacial periods (marine isotope stages 2, 4, 6) and the high monsoon precipitation corresponding to interglacial periods (marine isotope stages 1, 3, 5).

An attempt has been made to summarise the evolution of the Ghaghara sub basin of Middle Ganga Alluvium.

The Geoscience of Wine: The influence of surficial geology on viticulture in Atlantic Canada

MITCH J MARACLE[1]*, Acadia University (mitchell.maracle@outlook.com)
IAN SPOONER[2], Acadia University
DENISE BRUSHETT[3], Nova Scotia Geological Survey

Abstract

Terroir encompasses the distinctive characteristics of a specific location that contributes a unique taste to wines. The Province of Nova Scotia is located on Canada's Atlantic coast, hosts an emergent cool climate wine grape growing region and is one of North America's fastest growing wine districts. This study which focuses on the Gaspereau Valley region of Nova Scotia, investigates the association between different surficial landscape features that host vineyards and the geochemistry of sediments in these landforms that is necessary for Vitis vinifera and hybrid varietal growth and vigor. Vitas vinifera requires specific metals (Ca, K, Mg, Cu, Fe, Mn, Zn, Mo) obtained from the subsurface to regulate growth and vigor, these metals also impart specific aesthetic qualities to wine and contribute to a wines sense of place and the regions terroir.

Atlantic Canada was subject to multiple ice advances during the last glacial period (late Wisconsinan) which produced distinct sediments and complex landforms that were resolved using LiDAR classification mapping. Field investigations guided by LiDAR were used to differentiate multiple stepped glaciofluvial terraces now occupied by vineyards that exist on the south side of the Gaspereau Valley. Further landforms delineated in the valley hosting vineyards include colluvium, till blanket (> 5 m sediment thickness), river terraces, and modern alluvium. In the Grand Pré region of Nova Scotia vineyards occupy drumlins in which multiple subglacial traction tills with distinct characteristics indicate locally dynamic ice flow directions and sediment sources. Soil samples were collected from the B and C soil horizons to a minimum depth of 0.6 m in four vineyards occurring on different landforms. Preliminary results of soil sample analyses indicate that the classified landforms have unique sedimentology and elemental concentrations. In particular, Cu is most prevalent in the glaciofluvial terraces and K is elevated in streamlined subglacial traction tills. This study contributes to an understanding of the relationship between glacial landforms that exhibit specific and desirable terroir characteristics and the geochemical benefits that each landform may provide. Understanding these relationships and characteristics will aid in identifying viable grape growing areas in glaciated terrains across the globe.

Snapshots of glacial forefields: mapping modern-day processes in central Chilean Patagonia

Paulina MEJÍAS OSORIO[1]*, University of Vienna (paulina.mejias-osorio@univie.ac.at)
Daniel LE HERON[2], University of Vienna
Ricarda WOHLSCHLÄGL[3], University of Vienna
Bethan DAVIES[4], Newcastle University
Bernhard GRASEMANN[5], University of Vienna

Abstract

Glacier recession is a global occurrence and, as this is happening, landforms are being constantly revealed. They offer invaluable insights into processes related to transport of sediment and meltwater, as well as the behavior of the ice itself. In Patagonia, some of the glaciers in the area have been well studied in terms of paleoglacier extent and a few of them are continuously being monitored due to their importance in relation to possible hazardous events (for example, glacial lake outburst floods) or the local tourism industry. However, there are no detailed investigations regarding the current geomorphology that can be observed at their margins, where changes are rapidly occurring. Using uncrewed aerial vehicles (UAVs), it is possible to efficiently gather data in areas with difficult access, which can be used for creating high-resolution maps that show the present state of glacial margins. The unique characteristics of certain landforms translates into information about the behavior of the glacier responsible for creating them, but also pose questions on the exact nature of their formation. The results presented here are geomorphological maps generated with data from a UAV that show the landforms at sites in the Northern Patagonian Icefield and the neighboring Monte San Lorenzo massif to the east, specifically from the forefields of Calluqueo, Río Tranquilo, and El Cuarenta glaciers. Through these maps, we seek to characterize landsystems models and further understand the glacial processes that are taking place today at a local scale, but with the potential to compare them to other places in the world.

Abstract

The Quaternary is an important period in the geologic time due to extreme climate fluctuations and modern human occupations. The Quaternary map shows the spatio-temporal distribution of rocks and sediments deposited during the Quaternary period. The Quaternary geological maps have been produced mainly in the United States and European countries since the 1970s, which were digitalized with high resolution in the early 2000s. In Korea, the Quaternary geological map project based on the Quaternary age dating, sedimentary stratigraphy, and paleo-environments of Quaternary sediments began in the 2010s. The Quaternary geological map of the Korean Peninsula provides the basic Quaternary geological information for land utilization for the Quaternary distribution area and estimating past and present changes in the surface environment. The Quaternary geological map was produced with the concept of a Quaternary superficial geology map, which identifies the sedimentation environment at a depth of about 1 m above the surface and displays it on the map. For this purpose, the surface distribution characteristics of the unconsolidated sedimentary layers formed in the Quaternary were investigated, and the unconsolidated sedimentary layers were extensively drilled to analyze the subsurface sedimentary layers distributed above the bedrock. In addition, the depositional time of the sedimentary layer was measured using 14-carbon radiocarbon and OSL (optically stimulated luminescence) dating methods. Through this, the chronostratigraphy was provided, and the three-dimensional distribution status and deposition time of the Quaternary sedimentary layer distributed on the bedrock were distinguished. The investigation of the distribution range of the Quaternary boundary of the research area was made through the analysis of old historical maps, numerical topographic maps(digital maps), aerial photos, and drone images. The presence or absence of the Quaternary sedimentary layer confirmed through the image data was finally confirmed through a field excursion. The sedimentation environment of the surface layer was classified either by observing the sedimentary layer from the outcrop or by the trench survey and drilling. In the Quaternary distribution area, deep drilling was performed on the bedrock to collect the unconsolidated sedimentary layer, and a description of stratigraphic characteristics was performed

on the borehole. Also, proxy analyses and absolute age dating were performed. Based on these results, the chrono-stratigraphy was divided. In this study, the Busan Quaternary map was produced with a 1:250,000 scale. In this map, the study area was largely divided into the southeast, northeast, mid-east, mid-west, northeast and northwest, and the map guidebook was explained based on the 1:50,000 geological map.

Hyun Ho Yoon[3], Korea Institute of Geoscience and Mineral Resources
Jin-Young Lee[4], Korea Institute of Geoscience and Mineral Resources
Jaesoo Lim[5], Korea Institute of Geoscience and Mineral Resources

Abstract

Sedimentary magnetism on tidal flat sediments remains less studied so far. The presence of extensive tidal flat sediments of Pleistocene to the present ages in the western and southern parts of the Korean Peninsula allows us a good opportunity to study them. Here we focus on acquisition and preservation of natural remanent magnetizations (NRMs) to explore the usability of tidal flat (or 'tidal mud') sediment as a recorder of Holocene paleomagnetic secular variation (PSV). From a tidal sediment core (called QJS29) in the Dongjin River estuary, paleomagnetic and mineral magnetic analyses, combined with dry density and X-ray fluorescence data, exemplify robust evidence for primary NRM acquisition and preservation depending on depth and sample dry density in the 2–3.9 m depth interval with muddy tidal sediments. Major NRM carriers for the samples are suggested to be mixtures of low-coercivity ferrimagnetic minerals, probably detrital magnetite and greigite of diagenetic and biogenic origins. It represents gradual increases in NRM acquisition efficiency and remanence stability and decrease in sample dry density when increasing depth. Well-defined stable characteristic remanence (ChRM) components could yield in the tidal muds below 3.075 m depth but could not in the upper 1.075 m-thick tidal muds (above 3.075 m depth). Then we construct a depth-varying record in ChRM inclination and declination (relative) and relative paleointensity (RPI). The constructed record reflects the local PSV between ~2 and ~4 kyr BP from correlation to available local reference curves. Given the available age information about the sedimentation, this suggests a temporal lag of the remanence acquisition (or lock-in) from sedimentation; in other word, a need of compaction by mass accumulation in the remanence acquisition. Consequently, our results suggest that post-depositional remanence acquisition mechanism could dominate the PSV-related ChRMs, even though the remanence carriers are combinations of detrital, diagenetic and biogenic sources. This study thus contributes to improve the muddy tidal sediment usability as a PSV recorder.

Sea surface temperature variations at Shushi bay in Tsushima island over the last 3 ka

Sujeong PARK[1]*, Korea Institute of Geoscience and Mineral resources (sujeongp@kigam.re.kr)
Jaesoo Lim[2], Korea Institute of Geoscience and Mineral resources
Sujin Kang[3], Korea Institute of Ocean Science and Technology
Kyung-Hoon Shin[4], Hanyang University

Abstract

To reconstruct the change in sea surface temperature (SST) at Sushi bay, located on the northeastern coast of Tsushima island over the past 3 ka, we used Alkenone unsaturation index (Uk'37; Prahl et al., 1988) and radiocarbon age dating results from SS1C core sediments (34°37.358′N129°27.105′E; 2.8m in length; 21.2m of water depth). The reconstruction of past SSTs over the last 3 ka reveals an average value of 22°C. This is similar to the current average SST of 21.5°C during spring to autumn (March to October) in study area over the last 30 years. According to previous studies, SSTs derived from the core sediments also accurately reflect the SST during spring to autumn. The current SSTs along the southern coast of the Korean Peninsula show significant seasonal variations, largely related to changes in the Kuroshio Current and its extension area. To evaluate the relationship between the past SSTs in the study area and the Kuroshio Current, therefore, we compared with SST values obtained from MD-81 sediment cores, located at the starting point of the Kuroshio Current in the western Pacific. The results indicate that the general trend of variations, including centennial fluctuations over the past 1000 years, closely correlates with the spring-autumn SST changes in study area and the SST changes in the western Pacific during the last 3 ka. Furthermore, the decadal to centennial fluctuation trends during this period correspond with changes in Total Solar irradiance, suggesting the SST variations in northeastern part of Tsushima coast were directly influenced by solar activity. Therefore, we aim to continue our research to assess the factors influencing the SST fluctuations along the southern coast and their relationship with climate change in the Korean Peninsula.

Abstract

Endorheic lake basins preserve great records of changes in regional hydrology and environmental conditions. In this study, we investigated sedimentation dynamics for the saline lakes in the arid region of Mongolia. Sediment core from the Boontsagaan lake, sediment traps samples from the lake and inflowing Baidrag river, and rocks from catchment mountain range were collected. Sediment characteristics, including organic matter (OM), carbonate (CaCO3), amorphous silica (A-Si), grain size, and mineral assemblages, were measured for both the sediment core and sediment trap samples. A chronology of the sediment core is given by the lead-210 measurement. The average sedimentation rate is 0.2g/cm^2/year. The comparison between climate factor and sediment characteristics indicates: (1) grain size is correlated to wind strength, (2) amount of sedimentation possibly correlated to precipitation, and (3) amount of carbonate increase in a dry climate inducing period. Sediment trap samples show authigenic carbonate in lake but not in river.

A catchment rock sample were analysed by the fission track method, the low temperature thermochronological technique, to estimate the average erosion rate in the catchment. A rock was crushed, served, then magnetic minerals were removed. By the heavy liquid separation, apatite was separated and dated. A sample from high elevation show younger ages than a sample from low elevation, probably indicating higher average erosion rate for high-elevation samples. The erosion was basically very slow (a few mm /100 yrs).

Reconstruction of Sedimentary Environment on the Western Shelf of the South China Sea since the last deglaciation

Yang LI[1]*, China University of Geosciences, Beijing (13102131738@163.com)
Yan LI[2], China University of Geosciences, Beijing
Yu long XUE[3], Marine Geological Survey Institute of Hainan Province
Mian jin CHEN[4], China University of Geosciences, Beijing
Chang liang TONG[5], Marine Geological Survey Institute of Hainan Province
Xue mu WANG[6], Marine Geological Survey Institute of Hainan Province

Abstract

Climate change has influenced the marine-terrestrial environmental evolution in the geological past. The climatologically driven sea-level rise resulted in transgression during the interglacial period. Meanwhile, the erosional and source-to-sink processes were also largely affected by precipitation, vegetation cover, fluvial discharge, etc., controlled by the climatological condition.

Paleogeographic condition and sedimentary environment have been changed significantly in the western shelf of the South China Sea (SCS) since the last deglacial period (~18 ka to present). In this study, the upper 20 m of a sediment core NH01 (-73.5 m bsl) collected from the eastern neritic area of the Hainan Island in the SCS was used for chronological and sedimentary environmental investigations. In total of seventeen samples were collected for OSL dating. Foraminifera collected from two layers were used for radiocarbon dating. Diatom analysis was conducted to explore evolution of the sedimentary environment since the last deglaciation.

The outcome showed that the sedimentary sequence of the core NH01 comprises terrigenous deposits and marine deposits since last deglaciation (18.3 ka). For testing the reliability of the optically stimulated luminescence (OSL) dating, the quartz (post-IR blue and post-IR pulsed) OSL, K-feldspar and polymineral post-IR IRSL signals were applied and compared with radiocarbon ages. The consistent between luminescence signal and radiocarbon ages shows that the luminescence chronology is reliable.

During the pre-Holocene (18.3-10.6 ka), the Sedimentation rate (SR) was 0.08 cm/yr, the west shelf of SCS was submerged by seawater after 15 ka. While the abundance of diatoms was extremely low, several marine diatom fragments were identified. During the early Holocene (10.6-9.2 ka), the SR was 0.5cm/yr. The sea level rose rapidly, and reached -28 m bsl from -48 m bsl. The abundance of diatoms suddenly increased, with the dominant species of *Paralia sulcata-Cyclotella striata*. During the 9.2-6.9 ka, the SR was 0.1 cm/yr, the sea level has reached current level, but no diatoms were found. As an important environmental indicator, the diatoms assemblages recorded the sedimentary environment evolution of the west shelf of SCS since the last deglaciation controlled by the East Asian summer monsoon, sea level changes and Paleogeomorphology.

[Keynote] Exploring Desert Margins: Interdisciplinary Insights into Climate Dynamics, Human Migration, and Environmental Change

HEMA ACHYUTHAN[1]*, Centre for Environmental Studies, Anna University, Chennai 600025 (hachyuthan0@gmail.com)

Abstract

The desert margins are crucial hotspots, connecting between arid and humid ecosystems and exhibiting high sensitivity to climate changes. These regions have undergone significant environmental shifts during the late Quaternary period, making them susceptible to desertification and drought during prolonged arid conditions, resulting in temporary expansions and contractions of the desert margins. Many of these marginal areas preserve typical arid to semi-arid landforms, representing phases of drier and semi-humid late Quaternary climates. They have also served as corridors for human migration since MIS 5/6, with one notable example being the Thar Desert of Rajasthan, India. Given that drylands and desert margins are home to large populations, it is imperative to understand the geomorphic and anthropogenic processes responsible for climate shifts in these regions. These areas provide suitable sites where different paleoclimatic phases can be identified alongside human activities. Since the 1980s, numerous researchers have dated and excavated sites in these areas. Data from these sites have been instrumental in reconstructing paleoclimate shifts/events using fossil desert landforms, area reliefs, Quaternary sediment deposits, duricrusts, palaeosols, and archaeological evidence.

The application of OSL and 14C dating have facilitated correlations for the timing of aeolian deposition in deserts. Our data indicates that due to the onset of aridity, aeolian deposits began forming around 350 ka, followed by the formation of reddened paleosols. Between 200-150 ka, aridity intensified, accompanied by sporadic but intense aeolian deposition, river system drying, and declining groundwater levels. Aeolian phases occurred between 100 and 115 ka, 75 ka, 55 ka, 30 ka, and 25 ka with intermittent paleosol formations of varying thickness. During the LGM, the eastern margin of the Thar experienced intense aridity, although wind strength was insufficient for extensive aeolian accumulation. However, a climatic optimum period (7–6 ka) following the LGM witnessed a resurgence in aeolian activities. More recent phases of aeolian activity have been recorded between 5–3.5 ka and 2–0.8 ka. The lakes that are saline today were carrying fresh water and were probably interconnected, forming a major river system. Through this corridor, early humans likely migrated inland 'Out of Africa'. Based on Salt Lake studies, the lakes were hypersaline between 15 and 9 ka and relatively less saline or with fresh water between 7.5 and 6 ka. Most lakes dried up around 4 ka and became ephemeral after 1 ka. The lakes like Kanod and Bap-Malar remained saline from 9 to 6 ka while the Eastern margin lakes like Didwana, Tal Chapar, and Jhorda among others had fluctuating saline to fresh hydrology from 9 to 4 ka. Sites with microblade technology ranging in age from late-Pleistocene to mid-Holocene, as known from our studies at Sam (14 ka) and Jamba (7 ka), show human adaptation to arid, wet semiarid, and semiarid environments. Foraging communities had a symbiotic relationship with technologically

advanced food producing people in the eastern margin of the Thar Desert during the Medieval period.

Luminescence Dating Holocene Sediments from the Mongolian Forest Steppe

Manfred FRECHEN[1]*, LIAG (Manfred.Frechen@leibniz-liag.de)
Junjie Zhang[2], LIAG
Michael Klinge[3], University of Göttingen
Daniela Sauer[4], University of Göttingen

Abstract

The central-Asian forest-steppe forms the transition between the Gobi Desert in the south and the Siberian taiga in the north. In this sensitive landscape, even slight climatic shifts and minor human influence may lead to changes in vegetation patterns and geomorphological processes. Numerous alluvial and colluvial geoarchives, including successions of palaeosols and periglacial, aeolian, alluvial and colluvial sediments, indicate that diverse geomorphological processes have been active with varying intensity in different periods over the Holocene, shaping this landscape. Characteristic dark sediment layers with soil material, charcoal and plant remains are often intermingled within the sediment-palaeosol successions. They suggest that very often fires were the triggers that disturbed the vegetation cover and induced soil erosion. During the early Holocene, the region was widely covered by Siberian larch forests. A well-developed palaeosol is widely distributed giving evidence for a phase of relative geomorphological stability. Geomorphological processes substantially intensified around 4.5 ka, as evidenced by radiocarbon and luminescence age estimates. Although the climate became more humid, forest fires became more frequent than during previous warmer and drier periods. With the development of pastoralism since the early Bronze Age and associated population growth, the grazing pressure in the region increased.

Luminescence and radiocarbon dating methods are mandatory to set up reliable chronological frameworks for sedimentary systems to reconstruct climate and environmental changes quantitatively through time. Colluvial and alluvial sediments were sampled for luminescence and radiocarbon dating in detail. To some extend a discrepancy between radiocarbon and luminescence dating was found. Radiocarbon ages significantly underestimated the previous IRSL dating results. Therefore, quartz and feldspar minerals were investigated in detail to overcome the problem of insufficient bleaching and the problems encountered in the dim quartz OSL signals. We tested K-feldspar single aliquot (1 mm and 2.5 mm) for pIRIR dating to overcome the problem of the dim signal of quartz. Furthermore, single grain dating was also conducted to further address the problem of insufficient bleaching of the pIRIR signals, and OSL dating of quartz specimen was tested and found successful for a few samples. The preliminary established robust chronological framework indicates, in contrast to previous studies, an agreement between radiocarbon and luminescence dating. The robust data set and chronological framework will be presented in relation to the geomorphological processes.

Age dating of lava plateau and paleolake sediments formed by dammed lava plateau in Yeoncheon, the center of Korean Peninsula

JIEUN KWON[1]*, University of Science and Technology (kge3707@kigam.re.kr)
JIN CHEUL KIM[2], Korea Institute of Geoscience and Mineral Resources
MIN HAN[3], Korea Institute of Geoscience and Mineral Resources
YOUNGWOO KIL[4], Chonnam National University, Department of Energy and Resource Engineering
SEI SUN HONG[5], Korea Institute of Geoscience and Mineral Resources
HANWOO CHOI[6], Korea Institute of Geoscience and Mineral Resources

Abstract

In the Yeoncheon-Jeongok area of Gyeonggi-do in the center of the Korean Peninsula, Quaternary basaltic rocks occur as volcanic plateau and river cliff and representative Paleolithic sites of the Korean Peninsula are distributed. Though, Scientists have already reported for studies on several basalt outcrops, the results of dating vary depending on the region. In addition, it has been reported that paleolakes have been formed in the area by a lava dam formed by the flow of the Yeoncheon lava plateau. By dating the basalts of borehole inside the lava plateau and paleolake sediment core, this study aims to make a comprehensive interpretation of the formation period and distribution of the Yeoncheon lava plateau and to present the ages of the paleolake sediments for the first time. We obtained on total 63 Ar-Ar dating results for basalt outcrops and basalts at boreholes in this area and conducted OSL dating for sampling three or more materials at equal intervals of about 1 m each on 4-5 cores. As a result of Ar-Ar dating of basaltic rock, two different basalt were identified as distinctive periods. The weighted average age of each period is about 520 ka and about 170 ka. In the Jeongok-ri area of Yeoncheon-gun, old basalt rocks of about 520 ka form lava plateau at a position of 50 to 55 m above sea level. The basalt rocks of about 170 ka are distributed from Eundae-ri to Tonghyeon-ri in Yeoncheon-gun and were formed at an elevation of 65 to 70 m above sea level. Furthermore, to confirm the upper age limit, additional TT-OSL dating was performed on paleolake sediments and the age results of the existing OSL and TT-OSL were compared near Chatan river and downstream of Yeongpyeong river, respectively. As a result, paleolake sediments were mainly deposited during the Marine Isotope Stage(MIS 5: 130~80 ka), which corresponds to the last interglacial period. We date the uppermost paleolake sediments to 80 ka, suggesting a discontinuous boundary between the uppermost paleolake sediments and overlying fluvial sediments deposited by a fluvial environment after end of the lacustrine environment. It is interpreted that paleolake suddenly collapsed around 80 ka. Understanding the formation period and distribution of the Yeoncheon lava plateau and the age of paleolake sediments above it would provide interpretations of Yeoncheon's Quaternary formation and ancient river assumption, and provide clues to tracking the climate and ecological environment at the time human beings moved and settled.

Exploring palynofacies and sediment texture dynamics in subtropical floodplains along the Gomati River, Lucknow, India: Transition from Suburban to Urban Environments

POOJA TIWARI[1]*, BABASAHEB BHIMRAO AMBEDKAR UNIVERSITY LUCKNOW (pooja.tiwari@bsip.res.in)
BISWAJEET THAKUR[2], BIRBAL SAHNI INSTITUTE OF PALAEOSCIENCES LUCKNOW INDIA

Abstract

The study delves into the intricate interactions between hydro morphodynamics and vegetation, integral components of fluvial bio morphodynamics in actively meandering rivers. Focusing on the Gomati River in Lucknow District, Uttar Pradesh, India, the research examines spatial patterns of sedimentary organic matter (palynofacies) dynamics across a 38 km stretch, spanning from sub-urban to urban reaches within the river valley. Through analysis of palynofacies and grain size data from thirteen surface sediment samples, the fate of organic matter in this area is investigated, shedding light on its transportation, deposition, alteration, preservation, and degradation processes. The study delineates shifts in the composition of palynofacies associations—including phytoclasts, palynomorphs, and amorphous organic matter (AOM)—in conjunction with variations in grain size, providing insights into the depositional mechanisms at play. Utilizing CONISS cluster analysis, four distinct zones are identified, indicating differing degrees of palynofacies degradation and alteration, with urban areas exhibiting higher levels compared to sub-urban regions characterized by minimal interference with natural settings. Principal Component Analysis (PCA) is employed to elucidate the relationship between grain size and palynofacies, highlighting correlations within the meandering fluvial system of the Gomati River. By discerning the behavior of palynofacies within floodplain deposits, the study offers valuable insights into regional aspects of fluvial sediment disposition. Furthermore, the research endeavors to compare contemporary urban and sub-urban settlement patterns, providing a lens through which to understand the historical growth, dispersal, and decline of human settlements in the region. Overall, this study contributes to a deeper understanding of the complex dynamics shaping fluvial landscapes and human settlement patterns.

[Keynote] Sahara's surface transformation forced an abrupt hydroclimate decline and Neolithic culture transition in northern China

Hao LONG[1]*, Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences (NIGLAS) (longhao@niglas.ac.cn)

Abstract

The remote forcing from land surface changes in the Sahara is hypothesized to play a pivotal role in modulating the intensity of the East Asian summer monsoon (EASM) through ocean-atmospheric teleconnections. This modulation has far-reaching consequences, particularly in facilitating societal shifts documented in northern China. Here, we present a well-dated lake-level record from the Daihai Lake Basin in northern China, providing quantitative assessments of Holocene monsoonal precipitation and the consequent migrations of the northern boundary of the EASM. Our reconstruction, informed by a water-and-energy balance model, indicates that annual precipitation reached ~700 mm during 8-5 ka, followed by a rapid decline to 550 mm between 5 and 4 ka. This shift coherently aligns with a significant ~300 km northwestward movement of the EASM northern boundary during the Middle Holocene (MH), in contrast to its current position. Our findings underscore that these changes cannot be entirely attributed to orbital forcing, as corroborated by simulation tests. Climate model simulations deployed in our study suggest that the presence of the Green Sahara during the MH significantly strengthened the EASM and led to a northward shift of the monsoon rainfall belt. Conversely, the Sahara's reversion to a desert landscape in the late Holocene was accompanied by a corresponding southward retraction of monsoon influence. These dramatic hydroclimate changes during 5-4 ka likely triggered or at least contributed to a shift in Neolithic cultures and societal transformation in northern China. With decreasing agricultural productivity, communities transitioned from millet farming to a mixed rainfed agriculture and animal husbandry system. Thus, our findings elucidate not only the variability of the EASM but also the profound implications of a remote forcing, such as surface transformations of the Sahara, on climatic changes and cultural evolution in northern China.

Sr-Nd isotopic composition of the Quaternary brown clay-silt sequences in the Jeongok Paleolithic site, Korea: Implication for sediment provenance

Hawon YUN[1]*, Department of Environment and Energy, Jeonbuk National University (yunhawon@jbnu.ac.kr)
Inah SEO[2], Department of Earth and Environmental Sciences, Jeonbuk National University
Jin Cheul KIM[3], 3Climate Change Response Research Division, Korea Institute of Geoscience and Mineral Resources

Abstract

The origin of the Quaternary brown clay-silt (BCS) sequences at the archaeological site in Jeongok-ri, Yeoncheon-gun, Korea, has been debated regarding its relation to the timing of the Paleolithic artifacts. Proposed mechanisms, such as eolian and fluvial processes, each suggest distinct timelines and archaeological implications for the Korean Peninsula. The source-to-sink relationship between the BCS sequences and the potential source regions, such as the Chinese Loess Plateau (CLP) and local landmasses, is not straightforward because of the intense weathering and fine grain sizes, making it challenging to employ traditional provenance indicators. In this study, Sr and Nd isotope analyses are conducted on the 7.5 m-long sediment core (21JG-02) obtained from the E55S20IV pit of the Jeongok Paleolithic site to determine its provenance. The upper (0-3.6 m depth) section of the core, previously classified as a BCS sequence based on grain size, magnetic susceptibility, and geochemical properties, exhibits distinct 87Sr/86Sr and εNd(0) values compared to the lower section (>3.6 m depth), which was identified as a fluvial deposit. Notably, the εNd(0) values, minimally affected by grain size, in sediments from the upper section are similar to those of Yangtze and Yellow River sediments flowing through the CLP and surface sediments of the Yellow Sea basin. Conversely, sediments from the lower section exhibit similar 87Sr/86Sr and εNd(0) compositions to Korean river sediments and show down-core changes suggestive of a mixture with the detritus derived from the Jeongok Basalt, the bedrock. Combining these results with previously reported age dating results, the lower section originated from local sources in the Korean Peninsula through the fluvial process during marine isotope stages (MIS) 7, while the upper part, the BCS sequence, was derived from the CLP or Yellow Sea basin by the eolian process during MIS 6.

Taxonomic research on the Cenozoic gastropods from Qaidam Basin and their palaeoenvironmental significance

Tingting YU[1]*, Nanjing institute of geology and paleontology (ttyu@nigpas.ac.cn)

Abstract

Gastropoda belongs to the phylum Mollusca with a wide variety and is the second class of the animal kingdom. Gastropods are common fossils in the Cenozoic non-marine strata with great biostratigraphic and paleoenvironmental significance. The Cenozoic gastropods are abundant in the Qaidam Basin but have been little studied, resulting in the unclear appearance of the Cenozoic gastropod fauna in the basin, and reducing the effect of gastropods on biostratigraphic correlation and paleoenvironmental reconstruction. The palaeoenvironment reconstruction will be based on the facies analysis and compared to the paleoecology of the gastropod fauna as derived from the ecological characteristics of recent congeners. This project focuses on the Cenozoic gastropods in the Qaidam Basin to make the following studies by using multidisciplinary techniques: 1) make taxonomic study of these gastropods by adopting the latest cladistic systematics classification method, and using geometric morphometrics to distinguish the morphological differences between important genera and species; 2) recover the appearance of the Cenozoic gastropod fauna in the Qaidam Basin and conduct regional and intercontinental biostratigraphic correlations; 3) restore the paleoenvironment and paleoecology based on petrographic and taphthological analyses, combined with ecological attributes of gastropods and geometric morphologic data. This project aims to provide basic materials of gastropod biostratigraphy, taphonomy, biogeography and paleoecology for the research of Cenozoic Qaidam Basin.

The Geological Evolution and Palaeoclimatic Significance of the Temburong Peatland, Brunei Darussalam

Adlina MISLI[1]*, Universiti Brunei Darussalam (adlinamisli@gmail.com)
Basilios Tsikouras[2], Universiti Brunei Darussalam
Stavros Kalaitzidis[3], University of Patras
Elena Ifandi[4], Universiti Brunei Darussalam
Kimon Christanis[5], University of Patras

Abstract

Tropical peatlands are significant carbon sinks and freshwater stores and they comprise vital ecosystems governing the biodiversity. Furthermore, these peatlands serve as crucial palaeoclimatic and palaeoenvironmental archives, enriching our comprehension of sustainability and the dynamics of climate change. Peatlands worldwide face significant stress, yet Brunei Darussalam hosts some of the last remaining intact peatlands. These pristine ecosystems are invaluable for unravelling the geological evolution and the intricate conditions leading to peatland formation. Geological studies focusing on these last peatlands are limited, with particularly the Temburong region being understudied. This area is associated with a complex network of maeandering rivers and tributaries, which make up complex landforms and ecosystems. Peat formation in Temburong began approximately 2,500 years BP, during a Neoglacial cooling period, likely in an estuarine environment, representing a migrated palaeoshoreline. The Temburong peat, up to 130 cm thick, begun accumulating in a topogenous mire; it displays relatively low moisture, higher ash yield, and more acidic pH values, compared to the top 20-30 cm layer beneath the surface, which is accumulated in an ombrogenous mire. Peat accumulation rates are generally low, ranging between 0.4 mm/year to 0.5 mm/year, analogous to other synchronous, coastal peatlands of Southeast Asia. Variations in electric conductivity, coupled with lithological patterns, as well as proximate and ultimate analyses, are consistent with fluctuations in sea level and environmental changes during the peatland evolution. Literature data indicates climatic fluctuations during late Holocene with some Neoglacial cooling events that may have resulted in eustatic sea-level changes and therefore, have affected the evolution of the coastal Temburong peatland.

Insights into the Palaeoclimatic and Palaeoenvironmental Evolution of Brunei Darussalam through the Window of Tasek Merimbun Peatland

Basilios TSIKOURAS[1]*, Universiti Brunei Darussalam (basilios.tsikouras@ubd.edu.bn)
Muhammad Syazwan OMAR[2], Universiti Brunei Darussalam
Stavros KALAITZIDIS[3], University of Patras
Elena IFANDI[4], Universiti Brunei Darussalam
Kimon CHRISTANIS[5], University of Patras

Abstract

Tasek Merimbun Mire, situated in the central region of Brunei Darussalam, Borneo Island, occupies an area with altitudes ranging from approximately +3 to more than +18 metres. This peatland hosts an array of indigenous flora, including Shorea albida, Cyrrostachys renda, Pandace sp., Calamus rundentum, Areca nut, Lepironia articulata and subordinate Licuala spinosa. We performed four boreholes using a hand-driven peat sampler and the maximum observed thickness of the peatland is 10 metres. The collected cores show the predominance of peat overlying a clayey substrate with subordinate intercalations of peaty mud, mud, clay and clayey sand. Electrical conductivity values combined with B, Na and Mg contents, as well as the results of the proximate analysis, mainly S content, indicate a brackish-water influence in the lower peat strata, which subsequently changed to a freshwater system. This points to an initial accumulation of topogenous peat in a coastal lagoon or estuarine environment some 7,000 years ago, during the Holocene Climatic Optimum (HCO) period, followed by a rapid transition into a fluvial system and eventually to an ombrogenous peat. The accumulation rates are relatively fast during the early topogenous and the subsequent ombrogenous stages, up to approximately 3,400 years BP that is towards the end of the HCO, analogous to other peatlands of similar ages in the broad region of Southeast Asia. This period is followed by a significant deceleration of the peat accumulation until recent. X-Ray diffractograms reveal consistent influence of one or more rivers supplying mainly quartz, mixed clay layers, and chlorite. Signs of past (natural and/or anthropogenic) fire events manifest in charcoal remnants within peat layers. This study seeks to trigger further investigations into Tasek Merimbun's Lake formation, encouraging future research to incorporate palynological and petrographical studies for a more comprehensive understanding of this unique peatland ecosystem.

Abstract

The Acheulean-type hand axe, which was discovered only in Africa and Europe and never found in Asia, was discovered on the Korean Peninsula for the first time in East Asia in 1978 and attracted worldwide attention, but the debate surrounding the date of creation of the remains has continued in the archaeological community for 40 years. Although various absolute dating measurements have been conducted over the past 40 years since the Jeongok-ri relics were excavated and a lot of data has been calculated, the absolute chronology of the relics' formation has not yet been established.

The purpose of this study is to understand the geological distribution and formation of the Hantan-Imjingang River basin, identify the time of human emergence, and understand the characteristics of the climate and ecological environment at the time of human emergence to interpret interconnections. In this study, direct dating of the artefact-bearing layers was attempted by applying OSL techniques, which showed great potential for use in the accurate determination of the timing of deposition. To extend the age range of OSL dating, a thermally transferred optically stimulated luminescence (TT-OSL) signal and single-grain K-feldspars using the post-Infrared Infrared stimulated luminescence (pIR-IRSL) were also investigated. The Jeongok Basalts were directly analysed using the Ar-Ar method. 10Be dating from the unconsolidated gravel and sand layers underlying the Jeongok Basalt were dated for burial age. These results of multiple absolute dating methods allow the development of chronologies of the Jeongokri archaeological sites and constrain the timing of the earliest hominin occupation in South Korea.

Typhoon variability during the Holocene in East Asia and its linkage to ENSO activity

Jaesoo LIM[1]*, Korea Institute of Geoscience and Mineral Resources (limjs@kigam.re.kr)

Abstract

Understanding spatial-temporal variability in extreme hydrologic events driven by super typhoons over Asia is essential to test its controlling factors and predict its future change in anticipating global warming. Here we present a set of direct heavy-rainfall records for past 10,000 years recovered from wetland sediments of the two volcanic cones (Sara-oreum and Nongo-ak) in Jeju Island, where orographic amplification of precipitation is dominant and sensitive to typhoon influence. The reconstructed heavy rainfall index shows clear variability at decadal-centennial timescales and is similar to past records of coastal flooding events in the southern coast of Korea and typhoon-driven overwash events along the southwestern coast of Japan. These spatial similarities suggest that the reconstructed heavy rainfall index from the sediments of the volcanic cones can be used as an indicator for the past typhoon variability. Furthermore this typhoon index covering correlated well with past El Nin˜o/Southern Oscillation (ENSO) activity reconstructed from Ecuadorian high mountain area, confirming the existence of present linkage between more frequent typhoon occurrence and strong ENSO phases for the past 10,000 years at decadal to centennial time scales. This study demonstrates that the multi-decadal to centennial-scale typhoon variability in the western Pacific have been closely coupled to the eastern Pacific atmospheric-oceanic conditions than thought ever, needing better understanding of west-east Pacific teleconnection and its linkage to typhoon activity.

Holocene landscape variations of a large shallow lake in East Asia: Interactions between climate, hydrology, and human beings

Yawen GE[1]*, Hebei Normal University (geyawen@hebtu.edu.cn)
Changhong Liu[2], Hebei Normal University
Yuecong Li[3], Hebei Normal University

Abstract

The lack of continuous Holocene sedimentary records in large shallow lakes with river inputs poses a significant challenge for gaining a detailed understanding of long-term correlations among climate, environment, and human activities in densely populated areas worldwide. In this study, we reconstruct the comprehensive evolutionary history of Baiyangdian Lake, a typical open lake in East Asia during the Holocene, using AMS-14C dating and multiple sedimentary proxies. Our findings suggest that Baiyangdian Lake has gradually expanded since 10,300 cal yr BP and subsequently entered into a slow paludification process after 4,500 cal yr BP, particularly influenced by the 4.2 ka event. The Holocene optimal period (especially 6,500–4,500 cal yr BP) greatly accelerated the emergence of agriculture through slash-and-burn cultivation practices while human activities and concurrent marine incursions significantly altered both mountainous and plain landscapes. Since 2,700 cal yr BP, intensified human activities and hydrological processes have progressively driven Baiyangdian Lake towards its modern landscape. The representation of the 4.2 ka event in the sedimentary record significantly diverged from that of 8.2 ka, 6.8 ka events due to alterations in geomorphology and sedimentary environment, alongside inherent differences between climatic events themselves. These results contribute to our understanding of interactions between climate changes, hydrology, and human beings in densely populated areas of East Asia since the Holocene.

Uplift of the northeastern Tibetan Plateau leads to the extreme desertification in East Asia around 0.9 Ma

Xinbo GAO[1]*, Institute of Geology, China Earthquake Administration (Xinbo-Gao@outlook.com)

Abstract

Climatic extremes have destructive impacts on human society and the natural environment. In the wind-blown dust deposits (loess) of the Chinese Loess Plateau (CLP), several loess layers are exceptionally coarse-grained, representing deposition under conditions of extreme aridification. Among these loess beds, the upper sandy loess layer L9, corresponding to marine isotope stages 22-24, has attracted much research attention. An important reason for this is the widely reported remagnetization of the coarsest part of L9 in loess sections in the eastern Loess Plateau. However, our present work found that for the coarsest part of L9 in the loess sections in the western Loess Plateau, the reported remagnetization is disappeared. This spatially inconsistent magnetization pattern originates mainly from the different magnetic carriers of the characteristic remanent magnetization, hematite in the western Loess Plateau and magnetite in the eastern Loess Plateau. We propose that the enhanced glacial grinding and the denudation of mountains caused by the uplift of the northeastern Tibetan Plateau led to the production of enormous quantities of fluvial and fluvioglacial materials rich in hematite, which were supplied specifically to the western CLP. This uplift also resulted in the occurrence of extreme aridification in the East Asian interior at ~900 ka.

Hướng Nguyễn-Văn[7], Faculty of Geology, University of Science, Vietnam National University, Hanoi, 334 Nguyễn Trãi Street, Thanh Xuân District, Hà Nội, Vietnam

Abstract

Extreme weather and climate events in the Central Highlands of Vietnam result from the complex interactions of the various monsoon systems across Southeast Asia, leaving numerous traces in the geological records such as lake sediments and speleothems. However, paleoenvironmental reconstructions require a stable, high-quality source of information that is detailed and continuous over time, which has been a significant challenge in Vietnam. Our ~530 cm sediment sequence collected from Biển Hồ maar lake (14°03′ N, 108°00′ E), near the centre of the transitional region, shows the evolution of the diatom community adapting to changes in climate and the local environment. The record is uninterrupted throughout the Holocene with a diatom-sampling resolution of approximately 180 years on average. A regime shift characterised by two identified diatom assemblages is recognised around 7,800 cal BP, close to the transition from the Early to the Mid- Holocene. During the Early Holocene, the change in the ratio of Aulacoseira veraluciae to Discostella stelligera indicates the intensities of two opposing mechanisms: water-mixing and thermal stratification in meso-eutrophic conditions. Meanwhile, the replacement of the previous main species by the prevalence of Aulacoseira granulata var. granulata during the Mid- to Late Holocene suggests intense eutrophication caused by year-round water destratification and mixing. The morphological variability of this taxon also serves as an indicator of the driest times in the Central Highlands associated with major droughts across Africa and Asia continents.

Mariya Lukyanycheva[9], Institute of Archaeology, Azerbaijan Academy of Sciences

Abstract

The Pamir Mountains are located in the northwestern region of High Mountain Asia (HMA), which is known as the Third Pole (TP), the third-largest cryosphere on Earth that has a crucial impact on the global water cycle and climate system. The Pamir glaciers serve as primary freshwater supplies for the main rivers in the region, including the Amudaria and Syrdaria. During the Quaternary, these rivers carried glacial, alluvial, and slope deposits from the Pamirs across long distances to the Aral and Caspian areas, resulting in the formation of the Karakum and Kyzylkum deserts. The glacial history of the Pamir mountains has been reconstructed using geological and geomorphological data, as well as CRN dating. Despite this, the number, extent, and timing of Pleistocene glaciations in the Pamir region are still debatable. A comprehensive study of the Pamir-Alai region identified three major stages of glacial advance in the Middle and Late Quaternary, with the local LGM appearing to be during the Middle Pleistocene. In the southeastern Pamirs, the most extensive glaciation occurred during the Middle Pleistocene, when a large part of the mountains was likely covered by an ice cap and filled the main valleys of the Shahdara, Gunt, and Panj rivers. This paper contributes to understanding the southern Pamir's glacial history and the evolution of glaciation by presenting new data on a series of moraine ridges on the southern slope of Shakhdara ridge in the main valley of the Panj River and a thick lacustrine sequence in the tributary of the Panj, the valley of the Sary-Shitharv River. Obtained ages describe the timing of the glacially-dammed lake at Sary-Shitharv valley to MIS 6, providing the nearly oldest dated glacial advance in the Pamir area. These results are essential for the study of the Pamirs' glacial chronology and provide further evidence supporting the hypothesis that during the Middle Pleistocene, the Panj River valley was occupied by a massive glacier that extended from the southeastern part of the Pamirs.

Paleoenvironment evolution in the Weihe basin and its impacts on drainage systems of middle Yellow River since late Pliocene

Jingyun XIAO[1]*, Institute of Earth Environment, Chinese Academy of Sciences
(xiaojingyun@ieecas.cn)
Yougui Song[2], Institute of Earth Environment, Chinese Academy of Sciences

Abstract

The Yellow River, the second longest river in China, its development and evolution is an important geological problem that comprehensively reflects the changes of tectonic landform and environment in East Asia. The Weihe Basin is an excellent research location for understanding the evolution history of regional tectonics, climate, and hydrologic environment due to the accumulation of extremely thick and continuous sedimentary strata since Cenozoic. To help decipher the history of the development of the middle reaches of the Yellow River since Pliocene, the accurate paleomagnetic dating and analysis of grain size and magnetic susceptibility of sedimentary records in Weihe Basin are carried out. Our results suggest that the Weihe basin changed from lacustrine to fluvial deposition at ~2.6 Ma, subsequently transformed into eolian deposition at 1.2Ma. We conclude that the modern pattern of drainage systems in the middle reaches of the Yellow River was basically established in 1.2Ma, and the tectonic far-field stress from the continuing Tibetan Plateau uplift and eastern expansion created differential uplift/subsidence pattern, as well as the continuing lowering of base-level since 2.6Ma driving this integration. More interestingly, the information of the evolution of the East Asian monsoon system can be perfectly recorded in our basin during the period of tectonic stability. It provides good sedimentary evidence for understanding the evolution history of the Yellow River and its driving mechanism.

Incised-valley filling Sedimentation in response to Holocene Sea Level rise, Yeongil Bay, Southeastern Korea

Hyun Ho YOON[1]*, Korea Institute of Geoscience and Mineral Resources (hhyoon@kigam.re.kr)
Jin-Young Lee[2], Korea Institute of Geoscience and Mineral Resources
Jin Cheul Kim[3], Korea Institute of Geoscience and Mineral Resources

Abstract

Incised valley infilling deposits are closely related to sea level changes and are one of the important issues in the late Quaternary sea-level history. In Asia, numerous large river basins receive a large amount of sediments from the land, and the study of infilling deposits of incised valley systems has been a major focus. Yeongil Bay is located on the southeastern coast of the Korean Peninsula, featuring a funnel-shaped bay indentation. The small Hyeongsan River flows into Yeongil Bay and exits to the East Sea. During the Last Glacial Maximum (LGM), when the sea level was more than 120-130m lower than today, incised valleys were formed due to erosion by inflowing rivers. In this study, the sedimentary patterns of incised valleys since the LGM were investigated by analyzing sedimentary facies, optically stimulated luminescence (OSL), and radiocarbon dating of three sediment cores obtained from Yeongil Bay. The sedimentation sequence consists of fluvial lag and meandering river deposits (>12 ka), estuarine deposits (12-7.8 ka), and delta deposits (7.8-0 ka) in ascending order. Shoreface systems appear only in cores obtained from the outer part of Yeongil Bay, indicating that estuarine and delta systems were formed in a wave-dominated environment. Shoreface systems emerged by eroding estuarine deposits around 8.5 ka. Millennial-scale isochrons based on OSL and radiocarbon dating show that after the LGM, meandering river and estuarine systems were deposited through retrogradation, and delta systems through progradation. The modern deltas in the large river basins of Asia started to form during the mid-Holocene when the rate of sea-level rise slowed down, considering this period is important for the study of relative sea level (RSL). This study emphasizes the importance of both sediment supply and the capacity of accommodation space as factors in the delta initiation. The results provide significant insights into incised valley infill deposits and past environmental conditions and may help to better understand how coastal environments have changed with sea level changes.

Paleo-hydro environmental changes in Southeastern Mongolia from the Late Pleistocene to the Mid-Holocene: An analysis of lake sediment from Bayan Tohom Gobi

Sumin KANG[1]*, Kyung Hee University (sumin8185@khu.ac.kr)
Yukiya Tanaka[2], Kyung Hee University

Abstract

The Gobi Desert, located in southeastern Mongolia, is close to the limit of the EASM. Despite being extremely sensitive to climate change, only a few studies have been conducted on the paleoclimate in this region.

This study intends to provide a comprehensive analysis of the paleoenvironmental changes in southeastern Mongolia using lake sediments from paleolakes and classify the periods of dry and wet according to the effects of the EASM compared with the North Atlantic.

Lake sediments can provide proxy data and a continuous record of paleoclimate, and the analysis of the grain size and chemical properties of lake sediments and diatom can be used to reconstruct the environment around lakes.

The samples for analysis were obtained from Bayan Tohom Gobi, a depression in southeastern Mongolia. The grain sizes and geochemistry of the samples were analyzed to obtain proxy data. Furthermore, we carried out optically stimulated luminescence (OSL) and 14C dating of the sample sediments to investigate the paleoenvironmental changes in the region after the Late Pleistocene. We also use the diatom as an indicator of wet periods.

As a result, we obtained multi-proxy data from the Late Pleistocene to the Mid-Holocene by analyzing sediment core samples collected from three sampling sites in Paleolake Uidzen Nuur. The analysis results show that proxy data fluctuated wildly within the short period before 28 ka (OSL dating) and showed a huge decrease of around 10 ka. Fluctuation of proxy data means vegetation around the paleolake and precipitation. After comparing the results with previous data, the mean fluctuation of precipitation within a short period is associated with the D-O cycle in Hulu Cave (Northeastern China) and Ice core data (North Pacific). D-O cycle possibly affected the fluctuation of precipitation in southeastern Mongolia.

Thus, we provide evidence of a global-scale teleconnection by comparing these records with the paleo-hydrological records from the North Pacific region. This study will contribute to understanding global environmental changes during the Holocene and Late Pleistocene and highlight the interconnected nature of climatic processes across different areas.

Reconfirmation of the dating of Jeju Island's Suwolbong Tuff

youjin WOO[1]*, University of Science and Technology (youjin7308@kigam.re.kr)
Jincheul KIM[2], Korea Institute of Geoscience And Mineral Resources
Sei Sun HONG[3], Korea Institute of Geoscience And Mineral Resources
Jin-Young LEE[4], Korea Institute of Geoscience And Mineral Resources
Han Woo CHOI[5], Korea Institute of Geoscience And Mineral Resources

Abstract

Jeju Island is the Quaternary volcanic island located in Korea, and there are tuff called Oreum due to active eruptions of hydrovolcanic on the island. located in the southwest of Jeju Island Suwolbong Tuff is one of these tuff and is composed of pyroclastic materials. Suwolbong Tuff is created in as a mono-volcanic eruption, so there is no stratigraphic order.

According to previous studies, the formation age of Suwolbong Tuff is known to be about 18 ka when measured by Optically-Stimulated Luminescence (OSL) using quartz (Cheong et al., 2007). As per another previous study, the radiocarbon dating age of the unconsolidated sediments called the “Gosan Formation” under Suwolbong Tuff, is about 17 ka at the top (Lim et al., 2015). Therefore, the Suwolbong Tuff above the Gosan Formation was expected to be younger than 17 ka.

In this study, the depositional age was measured using single grain OSL dating, which determines the age by measuring 100 single quartz particles one by one. Then, the date is obtained through statistical processing. which was not preformed in previous studies. This study is conducted to re-evaluate previous OSL dating results of the Suwolbong Tuff. It is expected to find out the last hydrovolcanic activity on Jeju Island.

Electron Spin Resonance chronology and heavy minerals from the quaternary fluvial terraces of the Somme River (Northern France)

Rajib Kumar SAHA[1]*, Geological Survey of Bangladesh (rajibkumar.saha@gsb.gov.bd)
Pierre VOINCHET[2], Muséum national d'Histoire naturelle Département Homme et Environnement, UMR 7194 du CNRS
Pierre ANTOINE[3], Directeur de Recherche CNRS UMR 8591 CNRS-Univ. Paris I-UPEC Laboratoire de Géographie Physique, Environnements Quaternaires et actuels

Abstract

Chronological assessment is a fundamental requirement for comprehending the landscape's formation timing and reconstructing the connection between paleoenvironment and climate. With this goal samples from fluvial units of the Somme river stepped terrace system (Northern France) have been selected for a systematic application of a multi-center approach (Al, Ti-Li, and Ti-H) for Electron Spin Resonance (ESR) dating. This involves the examination of bleached quartz grains. Simultaneously, the sedimentary processes have been scrutinized through the identification of heavy minerals, achieved by both density separation and magnetic separation. The objective was to gather information on provenance and paleoenvironment, contributing to a comprehensive understanding of the archaeological context.

While the age estimates for the Amiens sites, "Rue du Manège" and "Ilôt des Bouchers," have associated uncertainties primarily stemming from challenges in long-term water content estimation, lithostratigraphy, and depth values, a Middle Pleistocene age has been assigned to these sites. This correlation is based on Marine Isotope Stages (MIS) and aligns with the Saalian Complex of Northwestern Europe chronosratigraphy. In contrast, the age estimation for Abbeville "Route de Paris," has been considered unreliable due to overestimation and non-repeatability with Al and Ti centers.

Most stable heavy mineral types are more prevalent in the 0.125 mm to 0.063 mm size fractions at the Somme River Valley sites sediments (the heavy mineral assemblages from the oldest part of the system are likely different from those of the Late Saalian terraces for instances, Ilôt des Bouchers). These minerals include garnet, epidote, green hornblende, augite, zircon, kyanite, staurolite, sphene, apatite, rutile, and tourmaline. Provenance tracks, primarily originating from sialic igneous rocks, have been defined based on granulometry, heavy mineral suites, and optical characteristics. The source rock has been identified as fluvioglacial Fenno-Scandinavian material derived from the Scandinavian Ice Sheets and the aeiolian transport of the minerals in loess sediments originated from the Eastern Channel area.

Abstract

Fluvial landforms and sediments with robust chrono-stratigraphy can be used to reconstruct paleoenvironments and link their relationships with paleoclimates. Quaternary landscape evolution in tropical river environments, such as Indonesia, remains poorly known, especially over Middle to Late Pleistocene time scales. The Kampar River is a meandering tropical river in Sumatra Island, Indonesia that has a gentle slope, sand-gravel beds and bends that migrated laterally due to bank erosion. This study provides a chrono-stratigraphic framework for the Late Quaternary period of the Kampar River to reconstruct long-term sedimentation events and investigate the drivers of morpho-dynamics, including climate change. Satellite images and drone imagery show the recent geometry of the river. Sedimentological analysis, utilizing X-ray diffraction and granulometry is used to investigate facies changes and paleoenvironments. A chrono-stratigraphy established with luminescence dating and fluvial modelling allows for a more precise reconstruction of alluvial history in response to environmental change. A simulation of fluvial dynamics was conducted using a numerical model of water flow and sediment transport, eRiDynas.

Results of sedimentological and luminescence dating analyses show that sedimentation of the Kampar River occurred in the Upper Middle Pleistocene with massive gravelly channel deposits. This happened in a period of high global glacier cover, cold conditions and low sea levels at Marine Isotope Stage (MIS) 6, possibly suggesting a significant increase in sediment supply and/or reduction in sediment transport capacity due to drier conditions. A hiatus in the sedimentary record suggests that sedimentation reduced substantially, and intensive erosion occurred during interglacial to glacial periods between MIS-5 and 4. In the Late Pleistocene, fining-upward sandy gravels were deposited at MIS-3, and the river became more associated with low amplitude point bars reflected in lateral accretion deposits. Overbank and chute bar formations were deposited and indicate the onset of large-scale flooding and more intensive bend-growth during the last glacial maximum (LGM). For the Kampar River, our results suggest that fluvial morpho-dynamics were primarily a consequence of climate-controlled sedimentation

processes rather than tectonic processes. These results are being combined to develop a model of fluvial dynamics to better understand the fluvial response to a changing climate. The model results are regarded as realistic based on the consistency of the simulated and actual mechanisms driving Kampar River’s evolution.

Dating the base of the Upper Pleistocene in Chinese and Tajik loess by OSL and its association with climatostratigraphy and chronostratigraphy

Liping ZHOU[1]*, Peking University (lpzhou@pku.edu.cn)
Jintang Qin[2], Peking University
Yuetian Li[3], Peking University

Abstract

One of the next priority tasks of the Quaternary stratigraphy community is to establish a Global boundary Stratotype Section and Point (GSSP) for the Upper Pleistocene Subseries, which was formalized with a provisional age of ~129 ka. To define its GSSP, a marine sediment record in Taranto, Italy and the EPICA Dome C ice core in Antarctic have been suggested as candidates. Once the boundary is ratified, it would not only serve as a chronostratigraphic marker but also carry specific regional climatic signatures reflecting a distinctive event of global significance. Loess-paleosol sequences in Eurasia have served as major climate archives on the continent. Their chronologic framework has been established by paleomagnetic reversals. The optically stimulated luminescence (OSL) method has been successfully employed to constrain the ages of the upper part of the sequences. Here we present results of OSL dating of four loess sections from northern China and southern Tajikistan. We show the effects of the choices of minerals and laboratory measurement conditions, and discuss their strengths and limitations. As the base of the Upper Pleistocene is associated with the onset of the Last Interglacial, a global warming event in the Earth system, the accuracy of the OSL ages of the Eurasian loess sequences is crucial for providing a basis for climatostratigraphic correlation. We evaluate the OSL age uncertainties and their chronostratigraphic implications with reference to the lithologic subdivisions of the loess and paleosols as well as to the other climate records on land and in the ocean.

A ~426 ka Antarctic methane jump at the onset of MIS 11 could mark a prospective second stage for the Middle Pleistocene Subseries

Martin J. James Head[1]*, Brock University (mjhead@brocku.ca)

Abstract

The 'Mid-Brunhes Event' (MBE) in the late Middle Pleistocene represents an abrupt step-change to climate cycles of generally increased amplitude and warmer interglacials from Marine Isotope Stage (MIS) 11 onwards, as revealed by Antarctic ice core records, the LR04 benthic foraminiferal isotope stack, and a long alkenone paleotemperature record from the central Mediterranean Sea. Other long-term changes include an abrupt weakening of the East Asian Summer Monsoon, suggesting an increase in average Northern Hemisphere ice volume. The Middle Pleistocene Subseries, formalized in 2020 with the Chibanian as its only stage, is the second longest subseries of the Quaternary with a duration of 645 kyr. Defining a second stage with its base coincident with the MBE would subdivide the Middle Pleistocene at its mid-point utilizing a major climate transition (Head MJ 2021, Prog. Earth Planet. Sci. 8: 50). The MIS 12/11 boundary (Termination V) marks the highest-amplitude climate oscillation of the Quaternary and constitutes a logical base for this new stage. In addition to being recognised by rapid changes in the marine record, this level appears to align with the bases of the Holsteinian, Hoxnian, Likhvinian, and Zavadivian regional stages across northwestern and central Europe, the Russian Plain, and the Ukrainian Loess Plain; and can be traced across the Chinese Loess Plateau. In detail, MIS 12 represents possibly the largest ice-volume expansion in the Quaternary, and MIS 11 is one of the warmest interglacials, spanning two precession cycles in which full interglacial conditions persist for nearly 30 kyr despite only modest orbital forcing (reviewed by Tzedakis PC et al. 2022, Quat. Sci. Rev. 284 107493). The unusual characteristics and duration of MIS 11 have been attributed to a combination of extensive ice coverage during MIS 12 and weak boreal summer insolation forcing in MIS 11. Deglaciation at the end of MIS 12 began just before peak northern hemisphere insolation with a weakening of the Atlantic meridional overturning circulation leading to activation of the bipolar seesaw and Antarctic warming. This is reflected in the EPICA DOME C Antarctic ice core record by a simultaneous rise in atmospheric temperature over Antarctica and a rise in CO2 attributed to Southern Ocean degassing. A sharp rise in methane in the EPICA DOME C core at 426 ka appears to correlate with a similarly rapid and pronounced shift to more negative δ18O values in the Sanbao Cave speleothem of China, probably reflecting an expansion of tropical wetlands at this time. A particular challenge in searching for a globally isochronous base in the early part of MIS 11 in both marine and terrestrial deposits is the slow eustatic rise and prolonged ice sheet decay through the early part of MIS 11c. Nonetheless, the methane jump at 426 ka in the EPICA DOME C core, coinciding with the onset of MIS 11 and abrupt warming in the mid- to low latitude North Atlantic, might serve as the primary guide to the base of the proposed second stage for the Middle Pleistocene.

CENOZOIC STRATIGRAPHY OF SOUTH AFRICA: CHALLENGES AND POSSIBILITIES

Greg A. Botha[1]*, 35IGC Legacy Fund/ IGCC/ University of KwaZulu-Natal (bothag@ukzn.ac.za)

Abstract

The Cenozoic stratigraphy of South Africa evolved progressively during regional geological mapping over the past 168 years. The diverse Cenozoic regolith distributed across the wide range of bedrock types and terrain morphological contexts has not been classified consistently. Although geological mapping here utilizes lithostratigraphy to organise the Cenozoic deposits, some extensive surficial units are only characterised using lithological descriptors. No formal biostratigraphic units have been defined and the application of “Land Mammal Ages” compiled from fossil type sites is not incorporated on geological map legends. An analogous archaeological cultural-historical “Technocomplex” stratigraphy has been derived to subdivide the stone age cultural material. This system has commonly been used as a relative dating framework where artefacts are associated with Quaternary deposits. The current status of regolith lithostratigraphy and the geochronological framework relative to global chronostratigraphy is addressed.

It is proposed that Cenozoic regolith stratigraphic units are differentiated into the terrain morphologically defined Geomorphic Province context as a means of correlating similar deposits across the subcontinent. For mapping units based on lithological characteristics that have not been well researched, or when their geochronological position is uncertain, the use of lithodemic nomenclature to characterise units in each Geomorphic Province is proposed as a temporary measure. This will enhance inter-regional correlation and encourage further research that could lead to formal lithostratigraphic descriptions.

Abstract

The method of authigenic 10Be/9Be dating, utilizing atmospheric cosmogenic 10Be and stable 9Be generated through rock weathering, holds promise for dating sediment deposition within the range of 0.2–14 Ma. Nonetheless, the disparate origins of these isotopes give rise to variations in initial 10Be/9Be ratios, influencing paleoenvironmental interpretations that have not been thoroughly investigated in previous studies. Our ongoing project is dedicated to empirically determining the variability in initial 10Be/9Be ratios within the depositional record across various sedimentological settings, encompassing Upper Miocene-Quaternary successions in the East Carpathian Foredeep and Pannonian Basin, as well as Holocene parasequences in the Po Plain. This overview outlines our current findings and provides recommendations for the method's application.

The sequence-stratigraphic framework relies on system tracts, which exhibit varying stacking patterns relative to changes in base level. The falling-stage and lowstand system tracts are

associated with decreases in base level and river incision in terrestrial environments, leading to the redeposition of older sediments. This can result in apparently older ages observed in alluvial successions. Changes in river networks during this process can significantly impact the delivery of 9Be due to changes in sediment provenance. As base level rises during the subsequent transgressive system tract, river delta retreat occurs, causing a noticeable decrease in 9Be delivery and variability of its spatial distribution. Furthermore, low rates of sedimentation can lead to post-depositional and diagenetic changes in the 10Be/9Be ratio. Hence, offshore muddy successions typically display considerable variability in initial 10Be/9Be. The highstand system tract is characterized by stable sediment supply under high accommodation rates and rapid burial of strata, thereby mitigating post-depositional processes. The stability of highstand settings results in low variation in initial 10Be/9Be ratios. n deep-water environments characterized by the dominance of turbidity currents, there may be instances of mud redeposition by hybrid event beds. These occurrences have been noted to result in apparently older ages, similar to the effects observed with incising rivers. Consequently, alluvial and deltaic deposits within the highstand system tract are deemed most suitable for dating using authigenic 10Be/9Be.

The study was caried out under the "New Generation Lithuania" plan (postdoctoral project CosmoLith, Nr. 10-036-T-0008) financed under the European Union economic recovery and resilience facility instrument NextGenerationEU, and by the Slovak Research and Development Agency contract No. APVV-20-0120.

Unravelling the chronology of the infill of glacially overdeepened structures in the northern foreland of the European Alps.

Gustav FIRLA[1]*, University of Natural Resources and Life Sciences, Vienna - Institute of Applied Geology (gustav.firla@boku.ac.at)
Christopher Luethgens[2], University of Natural Resources and Life Sciences, Vienna - Institute of Applied Geology
Clemens Schmalfuss[3], University of Natural Resources and Life Sciences, Vienna - Institute of Applied Geology
Stephanie Neuhuber[4], University of Natural Resources and Life Sciences, Vienna - Institute of Applied Geology
Markus Fiebig[5], University of Natural Resources and Life Sciences, Vienna - Institute of Applied Geology

Abstract

The European Alps were influenced by repeated glaciations during the Pleistocene. Outcrops comprising sediments associated with glaciations prior to the last are comparatively rare. Glacially overdeepened valleys and basins are prominent subterranean structures eroded by glacial and/or glaciofluvial erosion below the regional fluvial base. Most of these structures were later filled with sediment sequences. Some of the sequences have resisted subsequent glacial, glaciofluvial and non-glacial erosion and can therefore be used as sedimentary archives of pre last glacial cycles. The multinational pan-alpine research project ICDP - DOVE (International Continental Scientific Drilling Program - Drilling Overdeepened Alpine Valleys) currently investigates overdeepened structures with drill-cores and geophysical surveys on the northern side of the European Alps and uses them to better understand the complex interplay of glacial dynamics, climate fluctuations, and sedimentary processes in the Alpine realm during the Pleistocene. Deciphering this valuable information requires a reliable numerical chronology, which in the ICDP - DOVE project is going to be achieved by implementing a combination of different dating methods, including luminescence dating approaches. Here luminescence dating results from four drill-cores (Ranging from 136 m to 252 m in depth) retrieved from complementary overdeepenings in the northern foreland of the European Alps are presented. All drill-cores showed generally a similar sedimentary succession, with coarser sediments at the top (diamicton and gravel dominated sections) and fine-grained sediments at the base (sand and silt dominated sections). Sampling was focused on the fine-grained basal sections to constrain the infilling onset of the investigated overdeepened structures. Luminescence dating results were obtained with a pIRIR SAR measurement protocol using single grains of potassium rich feldspar as dosimeters. Single grain measurement approaches overcome the challenges associated with luminescence dating of poorly bleached pre-last-glacial cycle sediments. Signal averaging, occurring when using multi-grain measurement techniques can be addressed and the signal population that represents the last depositional event can be differentiated from the poorly bleached population (partially in saturation). The results showed a similar depositional timeframe during the penultimate glaciation

throughout the investigated overdeepened structures. Furthermore, the sedimentation rate was shown to be high as within uncertainty no age difference in the luminescence ages within the fine-grained sections of each drill-core could be detected. Here we present new chronological data that improves our understanding of the timing of glacial activity in the European Alps during the penultimate glaciation and the accompanying landscape evolution. Moreover, this study adds to the broader discussion about the advantages and challenges of single grain luminescence dating methods applied to poorly bleached sediments.

Abstract

Comprehending the intricate interplay among the atmosphere, hydrosphere, and cryosphere hinges on a thorough understanding of past ice sheet dynamics, a pivotal aspect for precise climate modeling. Yet, the absence of precise chronologies regarding the inception of the European Ice Sheet Complex (EISC) in the Baltic region undermines the reliability of existing models. To tackle this issue, the 'CosmoLith' project endeavors to furnish conclusive evidence by dating sedimentary deposits linked to the ice sheet's emergence. While such sediments are scarce in northern Europe, they are remarkably well-preserved in the southeastern reaches of Lithuania within the Baltic Highlands.

The primary sampling endeavor prioritized horizons both preceding and succeeding the lowest and oldest moraine conserved in the stratigraphic archives. The most recent pre-glacial sequence comprises alteration of sandy channel fills and of proximal floodplain deposits including muddy intercalations. The Vetygala exposure along the Šventoji River valley was meticulously sampled for clay specimens intended for authigenic 10Be/9Be dating, alongside sand specimens earmarked for combined exposure-burial dating utilizing in situ 10Be and 26Al. Furthermore, a series of samples was extracted from borehole cores housed within the repository of the Lithuanian Geological Survey. These samples encompassed the youngest alluvial mud underlying the oldest moraine, as well as alluvial and lacustrine mud overlaying the earliest preserved moraine, procured specifically for authigenic 10Be/9Be dating. The latter stratum also provided sandy and gravelly samples for the purpose of simple 26Al/10Be burial dating. Initial determination of the authigenic 10Be/9Be ratio will be derived from contemporary floodplain muds sourced from the Šventoji River and from deltaic muds sourced from the Holocene Nemunas River delta. All

samples are meticulously prepared for analysis on AMS ASTER (CEREGE, France), with the preliminary dating outcomes awaiting revelation at the time of this abstract's compilation.
The study caried out under the "New Generation Lithuania" plan (postdoctoral project CosmoLith, Nr. 10-036-T-0008) financed under the European Union economic recovery and resilience facility instrument NextGenerationEU.

‘Nicola’ bed deposition at the onset of the Quaternary ~2.58 Ma, Monte San Nicola, southern Sicily – geological background

Wieslawa RADMACHER[1]*, Polsih Academy of Sciences (violakrol@gmail.com)
Martin J. Head[2], Brock University
Antonio Caruso[3], Università di Palermo

Abstract

The base of Quaternary System, Pleistocene Series, Lower Pleistocene Subseries, and Gelasian Stage (~2.58 Ma) is defined by the Global boundary Stratotype Section and Point (GSSP) at Monte San Nicola (MSN), near Gela, Sicily, Italy. In spite of the utilization of the Gelasian Stage GSSP, initially ratified in 1996, to define the base of the Quaternary (and redefine the Pleistocene) in 2009, little new research was undertaken on the type section following its initial ratification until recently. The boundary coincides with the end of deposition of the ~20 cm sapropelic, laminated ‘Nicola’ bed which is widely exposed in the ‘badlands’ of the MSN. Detailed study of this unique layer based on trace fossil analysis and X-ray computed tomography shows that it was deposited in anoxic to disoxic bottom-water conditions, with a progressive increase in oxygenation towards the top (Radmacher et al., 2023, Marine and Petroleum Geology 158: 106552). The Nicola bed has been assigned to Mediterranean Precession Related Cycle (MPRC) 250. Sedimentation rates for the Pliocene–Pleistocene transition at MSN based on astrochronology are reported to be ~6.1 cm/kyr, although higher rates of ~11.7 cm/kyr characterise the Punta Piccola section located ~80 km to the SW and represent shallower conditions within the same basin. The Punta Piccola section also contains a distinctive laminated bed assignable to MPRC 250. The more recent Mediterranean sapropel S5 deposited during the Last Interglacial has laminations that reflect seasonal variability and can therefore be used to establish precise sedimentation rates. Our microscopic analyses of the Nicola bed at MSN suggest that the relatively undisturbed lamination occurring within the lowest 15.6 cm represents annual deposition. We aim to determine sedimentation rates through much of the Nicola bed, and hence estimate the duration of anoxic bottom-water conditions at MSN just before the beginning of the Quaternary. Sapropel formation in the Mediterranean has been connected to increased seasonal contrast and higher summer temperatures due to precession cycle maxima (insolation maxima) that forced a more northerly African rain belt. This would have elevated river inflow during times of summer monsoon, increasing surface water buoyancy during autumn/winter cooling, and interrupting bottom-water ventilation. We address this issue by studying the marine dinoflagellate cysts as they are sensitive to environmental changes near the sea-surface. In general, sapropelic layers are enriched in smectite, illite and chlorite transported by rivers, with decreased abundance of palygorskite, kaolinite, dolomite, quartz and feldspar that are rather transported by winds from Africa. Intercalated marls in contrast yield opposite trends, corresponding to the interplay between fluvial and eolian input into the Mediterranean basin. We therefore use clay mineralogy to refine our understanding of Nicola bed deposition at the beginning of the Quaternary within the broader

context of Northern Hemisphere glaciation. This ongoing research is part of GELSTRAT, an international collaborative program to further our understanding of the Neogene/Quaternary boundary at the type locality and enhance its recognition on a global scale.

Abstract

The Global boundary Stratotype Section and Point (GSSP) at Monte San Nicola, near Gela, Sicily, Italy, was proposed in 1996 to define the base of the Gelasian Stage, then the uppermost stage of the Pliocene Series, in recognition of the intensification of Northern Hemisphere glaciation. This GSSP became more important upon its approval in 2009 to define also the base of the Quaternary System and redefine the base of the Pleistocene Series. It is placed at the base of the marly layer immediately overlying the prominent, laminated, reddish, sapropelic Nicola bed, and has an astronomically tuned age of 2.58 Ma. The Nicola bed is assigned to Mediterranean Precession-Related Cycle 250 and aligns with an obliquity maximum representing Marine Isotope Stage 103, which, together with the Gauss–Matuyama paleomagnetic reversal, facilitates global correlation. Fine details of the stratigraphy nonetheless remain uncertain, including the precise position of the reversal relative to the GSSP at the type section. GELSTRAT is an international collaborative program inaugurated in September 2021 during an INQUA-SQS International Field Workshop focused on the reinvestigation and reanalysis of the Gelasian GSSP using modern methods and a broad range of proxies. Sampling across the boundary interval at the type section in September 2021 was supplemented by further fieldwork in April–May 2022 and resulted in the collection of 404 samples across a ~18 m stratigraphic interval spanning the GSSP and ranging from the top of bed A1 to ~10 m above the top of the Nicola bed (A5). Samples were collected at ~5 cm intervals. Approaches planned or in progress include: calcareous nannofossils, foraminifers, pollen, dinoflagellate cysts, macrofossils, ichnofossils, foraminiferal stable isotopes, organic geochemistry, clay mineralogy, magnetostratigraphy, and 10Be analysis. The first high-resolution planktonic oxygen and carbon isotope record has been obtained from the Gelasian type section, together with detailed marine and terrestrial biotic climate oscillations across the boundary. Our

dataset unravels the excellent climate signals recorded through the section and gives additional information on placement of the Gelasian GSSP within MIS 103 (e.g. Addante et al., 2024, Palaeogeog., Palaeoclim., Palaeoecol. 634, 111907). The Nicola bed is undergoing analysis at ultrafine stratigraphic detail employing many of the above approaches but also microstratigraphy, X-ray tomography, micro-XRF elemental analysis (ITRAX), micro-RAMAN spectroscopy, Fourier transform infrared spectroscopy (FTIR), and X-ray diffraction (XRD). Initial results show the rapid onset of anoxia at the base of the Nicola bed, followed by progressive dysoxia. The top of the Nicola bed is bioturbated over an interval of several centimeters. The overlying marl evidences a return to higher bottom water oxygen levels, although there appears to be a brief return to poor oxygenation (Radmacher et al., 2023, Mar. Petrol. Geol. 158, 106552). Refined characterization of the Gelasian GSSP will enhance its utility for precise recognition of the base of the Quaternary on a global scale, and our integrated paleoclimate reconstructions will illuminate a crucial phase of Earth history.

Vegetation dynamics and climate changes during the Onset of Northern Hemisphere Glaciation: Insights from the Monte San Nicola Section (central Mediterranean)

Adele BERTINI[1]*, Dipartimento di Scienze della Terra - Università degli Studi di Firenze (adele.bertini@unifi.it)
Gabriele Niccolini[2], Dipartimento di Scienze della Terra - Università degli Studi di Firenze
Houssem Tabbabi[3], Dipartimento di Scienze della Terra - Università degli Studi di Firenze

Abstract

The emergence of large ice caps in the Northern Hemisphere around 2.6 million years ago contributed to a significant shift in Earth's climate from a Cool- to an Icehouse climate state. Long-term changes in the Atlantic Meridional Overturning Circulation and the closure of the Central American Seaway have been proposed as primary factors driving this climate shift, clearly evident from Marine Isotopic Stage (MIS) 100 onwards along with the deposition of ice-rafted detritus in the North Atlantic. However, the specific mechanisms and regional responses to this transition in the Mediterranean area, particularly within the terrestrial ecosystems, remain subjects of debate. As part of the international GELSTRAT program, this research aims to investigate the flora composition, vegetation structure and the paleoclimatic changes in the central Mediterranean, at the Piacenzian-Gelasian transition as documented at Monte San Nicola (Sicily), GSSP section for the Gelasian Stage. 170 samples, collected across an 18-meter thick interval, encompassing the group of six precession-related darker beds A1, A2, A3, A4, A4/5 and A5 (Nicola bed), underwent chemical-physical processing at the Palynological Laboratory of the University of Firenze. Low to very low pollen concentrations characterized numerous samples particularly those from the base up to the top of A4 while samples from A4 are marked by higher concentrations. The high-resolution pollen analysis reveals distinct behavior of flora and vegetation according to a complex pattern of climate fluctuations on both Milankovitch and sub-Milankovitch timescales. Subtropical humid forest taxa are generally scarce, except for *Cathaya*. In contrast, deciduous temperate forest species, particularly deciduous *Quercus*, as well as altitudinal coniferous forest taxa such as *Picea* and *Abies*, along with open herbaceous vegetation, are abundant. They show distinct and significant expansions, indicating changes in temperature and humidity during successive glacial/interglacial phases. Above A5, there is a notable increasing trend in open vegetation and steppe taxa, exemplified by Amaranthaceae, *Artemisia*, and *Ephedra*, suggesting a significant expansion of dry conditions after 2.58 Ma. Conversely, just before this period, the increase in montane coniferous taxa, notably *Picea*, as observed in sapropel A4/5 (MIS 104), highlighted quite humid (and cold) phases. Comparing with other pollen records including those from Mediterranean sites along E-W and N-S transects contributes to a more comprehensive understanding of the Gelasian GSSP, enhancing its global correlation utility and facilitating accurate detection of the base of the Quaternary on a global scale.

Some problems of Pliocene – Pleistocene sediment studying at the East Siberian Sea according pollen data

Ekaterina NOSEVICH[1]*, Individual researcher (katenosevich@mail.ru)

Abstract

East Siberian Sea remains one of the most poorly studied area of Russian Arctic. New data on the geological sequence and genesis of Quaternary deposits were obtained during marine geological expeditions of carried out in 2018 and 2020. Six sediment cores were taken around New Siberian Islands archipelago. They were studied with grain-size, geochemical, diatom, palynological, and microfossil analyses and radiocarbon dating. The results of this research couldn't be properly interpreted due to controversy which was observed in the obtained data. Clay deposits of the underwater slopes of the New Siberia Island were dated 12040 – 12108 cal. BP (IGANams 8977), but their pollen spectra contained *Tsuga*, *Juglans*, *Corylus* and *Pterocarya* pollen, which are not characteristic of Upper Pleistocene deposits. Moreover, these spectra differed from each other and couldn't be correlated all together. These problems were previously described in the region (Biske, 1979; Trufanov et al., 1981), and pollen spectra could be attributed both Middle Pleistocene and Upper Pliocene or stay uncharacterized without any system.

In 2021 in frame of the deepwater drilling project, the new sediment sequence were taken. It comprise 40 m of Quaternary deposits and more than 100 m of Pre-Quaternary geological sequence. At the interval 69,5 – 98,0 m of the sequence sandy clay deposits were taken. They are also studied with grain-size, geochemical, isotope, mineralogical, diatom, palynological, and microfossil analyses. It was supposed that they belong to Eocene – Pliocene deposits according to their lithology and the depth of sampling. Their pollen spectra shows, that these sediments contain Quaternary pollen complex without species, specific to Pliocene. Results of our investigation of these sediments correlates with the previous research of the sedimentary sequence of East Siberian sea coastal margins and shelf (Gitterman, 1967; Bezrodnykh, 1981). This may prove the suggestion that in the deep cores Gelasian stage deposits may be found. At the covering Quaternary sedimentary sequence clay, silt and sand deposits were found. Our research is correlating with the investigations of Quaternary deposits of New Siberian Islands (Anisimov, 2002).

That allows us an assessment of Gelasian stage deposits mapping at the territory for the first time. Thus, it is now possible to describe main characteristics of Gelasian and Middle Pleistocene deposits of the territory and provide detailed description to distinguish them and to establish new characteristics for the local stratigraphy chart.

Hydrographic development of the northern South China Sea during the Pliocene–Pleistocene transition: The dinoflagellate cyst record of ODP Site 1148 – Preliminary results

Saif AL-SILWADI[1], University of Toronto
Martin J Head[2]*, Brock University, University of Toronto (mjhead@brocku.ca)

Abstract

The intensification of Northern Hemisphere glaciation that marks the Pliocene–Pleistocene transition is one of the most important climatic shifts in Earth's history. As a result of this shift, present day Quaternary climate patterns emerged and are characterised by high amplitude glacial–interglacial oscillations and climate cycle asymmetry. Although many mechanisms have been proposed for the intensification, including the onset of ocean stratification in the Northern Pacific at ~2.7 Ma and the closure of the Isthmus of Panama, the role and response of the Pacific Ocean remains poorly understood. The South China Sea is the largest marginal sea in the Western Pacific, and has frequently been used as a site for paleoclimatic reconstruction. This is due to its: high sedimentation rates that allow for fine-resolution reconstructions; semi-enclosed configuration that amplifies the impact of climatic changes; and geographic positioning that allows for influence from the evolving Tibetan Plateau, the Western Pacific Warm Pool and the East Asian Summer and Winter Monsoon systems. This makes it ideal for understanding the response of the Western Pacific across this interval of significant climatic transition. Dinoflagellate cysts, acritarchs and other palynomorphs are here used to assess the hydrographic evolution of Ocean Drilling Program (ODP) Site 1148, northern South China Sea, during the Pliocene–Pleistocene transition. This analysis covers approximately 111 samples from 2.85 Ma to 2.41 Ma with an average spacing of ~4 kyr, permiting a highly resolved paleoenvironmental reconstruction. An age model was developed using the oxygen isotope stratigraphy of Jian et al. (2003) that was tuned to the LR04 stack of Lisiecki & Raymo (2005). Preliminary results show over 50 marine palynomorph taxa, with fair to good preservation. Warm water dinoflagellate species (such as Polysphaeridium zoharyii) appear frequently throughout the section, along with Spiniferites bentorii and several Impagidinium species. This indicates a temperate to warm water, open ocean environment with a significant neritic component, and low temperature variation for most of the study interval. Fluctuations in the assemblages may be related to variations in salinity and nutrient levels. Salinity is also reflected in changes in the morphology of selected species, such as reduced process lengths of P. zoharyii and the cyst of Protoceratium reticulatum. Notable dinoflagellate cyst species include Atlanticodinium janduchenei, A. striaticonulum, Dapsilidinium pastielsii, Edwardsiella sexispinosa, Invertocysta tabulata, Operculodinium bahamense, and O. longispinigerum; and the acritarchs Cymatiosphaera? aegirii, C.? invaginata, C.? icenorum, C.? fensomei, and Nannobarbophora walldalei. Results from ODP 1148 will also be compared to dinoflagellate cyst analysis from International Ocean Drilling Project Site U1424 in the Sea of Japan and other sites in the North Pacific. This will facilitate a more detailed view of

paleoceanographic changes in the Pacific Ocean across the Pliocene–Pleistocene transition.

Abstract

The Global boundary Stratotype Section and Point (GSSP) for the Gelasian Stage currently defines the beginning of the Quaternary System and of the Pleistocene Series. It falls within a critical climate transition, including the progressive intensification of the North Hemisphere Glaciation (iNHG). As part of the GELSTRAT project, we provide an updating on planktonic foraminiferal δ18O record and calcareous plankton assemblage in the Monte San Nicola type-section (MSNt-s), to unravel the climate-induced surface water changes and improve precision of bioevents across the GSSP. Improving the data set on such a relevant section we intend to strengthen the correlation potential of the MSNt-s and of the GSSP itself outside the type-area. Following the recent climate reconstruction obtained on the type-section across Marine Isotope Stage (MIS) G4-103 , we now focus on the interval encompassing MIS 104 and MIS 100, not yet studied in type-section with a high-resolution detail. Our results are based on high-resolution sampling (5 cm), which allows a sub-millennial scale resolution (~800 years). The acquired dataset gives clear documentation of both orbitally forced glacial-interglacial phases and suborbital cyclicity, as well as precise position of calcareous nannofossil biostratigraphic constraints close to the GSSP. We also provide a first correlation between marine proxies and terrestrial signals across the interval, to describe mode and time of iNHG as recorded in the Gelasian type-section. The correlation with coeval Mediterranean and Atlantic records informs on the overall excellent climatostratigraphic signals recorded in the type-section.

Palynological implications for paleoenvironmental changes in the continental shelf, southeastern Korea, during the Plio-Pleistocene climate transition

Yongmi KIM[1]*, Korea Institute of Geoscience and Mineral Resources (kym1221@kigam.re.kr)
Sangheon Yi[2], Korea Institute of Geoscience and Mineral Resources
Dong-Geun Yoo[3], Korea Institute of Geoscience and Mineral Resources
Seok-Hwi Hong[4], Korea Institute of Geoscience and Mineral Resources
Gwang-Soo Lee[5], Korea Institute of Geoscience and Mineral Resources

Abstract

A palynofacies analysis was conducted using the core 19ESDP-104, obtained from the southeastern continental shelf of the Korean Peninsula, to reconstruct paleoenvironmental changes and estimated ages. The 19ESDP-104 core is mainly composed of silty clay, clayey silt, and sand, the present study focuses on the bottom 30 m of this core. Two palynomorph zones are established with a boundary 87 m depth based on pollen and dinoflagellate assemblages changes; P-I (87-100 m) and P-II (70-87 m). In the P-I zone, Quercus subgen. Cyclobalanopsis, Pinus-Diploxylon, relatively warm climate taxa, were abundant with a high proportion of amorphous organic matter (AOM). In addition, Polysphaeridium zoharyi, the warm water species, and the oceanic dinoflagellate species as Impagidinium spp. were observed in this zone. This result suggest relatively high sea level environment that was influenced by a relatively warm climate and warm water mass. On the other hands, in the P-II zone, Abies, Picea, and Pinus-Haploxylon, cold-dry conifer pollen assemblages were abundant. In addition, the prevalence of the xerophytic herb, Artemisia, Poaceae, Cyperaceae increases, and plant fragments smaller than 80 um is also observed in this zone. These results implying a colder climate and the discharging of large amounts of woody debris and herb pollen from the nearby exposed continental shelves by sea level decline. The last occurrence of pollen taxa from the Korean Peninsula and Japanese Archipelago in the Late Pliocene presented at 85 mbsf (top boundary of P-V zone). However, Impagidinium japonicum, extinct species at same era, is last occurred at 92 mbsf. The last occurrence depths of pollen and dinoflagellate age indicators are different. However, given the changes of lithofacies and palynofacies, our findings suggest that 85 mbsf (top boundary of P-V zone) is the Pliocene-Pleistocene boundary in core 19ESDP-104.

Continuous measurements in north China and culture experiments reveal the potential of leaf n-alkane carbon isotopes in paleoclimate studies

Guoan WANG[1]*, China Agricultural University (gawang@cau.edu.cn)
Minrui Shi[2], China Agricultural University

Abstract

Interpreting the climate information recorded by leaf n-alkane carbon isotopes (δ13Calk) in geological sediments facilitates climate prediction. However, this interpretation relies on the calibration of modern plant δ13Calk responses to climate change. Here, we present the first continuous calibration at the same place next to a meteorological station, which excludes errors in the commonly used spatial calibrations along environmental gradients, resulting in robust calibrations. δ13Calk was negatively related to precipitation but not temperature. 13C29 was most related to precipitation, followed by δ13C27-33 (i.e., the mean δ13C from n-C27 to n-C33), δ13C27, δ13C31, and δ13C33. If δ13Calk was only corrected for changes in δ13C of atmospheric CO2 (δ13Catm), the coefficients of δ13Calk vs. annual precipitation were -0.0048‰/mm, -0.0035‰/mm, and -0.0033‰/mm for δ13C27, δ13C29, and δ13C27–33, respectively. If correcting for changes in both δ13Catm and atmospheric CO2 concentration to δ13Calk, the coefficients of δ13Calk vs. annual precipitation were -0.0038‰/mm, -0.0025‰/mm, and -0.0023‰/mm for δ13C27, δ13C29, and δ13C27–33, respectively. Furthermore, we provided evidence for this relationship using a greenhouse study wherein water availability explained 97% of δ13Calk variance. Therefore, δ13Calk is a good indicator of precipitation, especially δ13C29. Finally, we conducted a reconstruction of pCO2 levels during the late Paleocene (pCO2(initial)) and the height of the carbon isotope excursion (CIE) (pCO2(excursion)) at the Paleocene-Eocene Thermal Maximum (PETM) by coupling the coefficients with other geological indicators. In the scenario where methane hydrates might have been the primary carbon source responsible for PETM warming, the estimated pCO2(initial) and pCO2(excursion) were 201−275 ppm and 911−985 ppm, respectively; whereas, in the scenario where volcanic CO2 emissions were the primary carbon source, they were 398−505 ppm and 1708−1815 ppm, respectively.

Fire history of the Chinese Loess Plateau under extreme warming scenarios: a case study of the loess-paleosol sequence L5-S5

lian LIU[1]*, Chinese Academy of Geological Sciences (liulianen@163.com)
bin shuai yang[2], Institute of Geomechanics, Chinese Academy of Geological Sciences

Abstract

This study analyzed the carbon concentration and carbon isotope composition of black carbon within the loess-paleosol sequence of the Chinese Loess Plateau, in order to study the history of natural fires under warming scenarios and to evaluate the possible incidence of fires in the future. Notably, the interglacials in this East Asian monsoon region were abnormally warm. The results from the interval of L5-S5 of the studied Xifeng section suggest that the principal factors controlling natural fires in an interglacial period (S5) and a glacial period (L5) were fuel load and fuel moisture level, respectively. The difference between the carbon isotope composition of black carbon and soil organic carbon during S5LL1 (marine oxygen isotope stage (MIS) 14) was due to the fact that the former records the more positive carbon isotope values of C3 plants caused by drought and low temperatures in the fire season, while the latter records the carbon isotope of plants throughout the year. The optimum temperature and humidity conditions during S5SS1 (MIS 13) were the most conducive to fires during the interglacial period of S5. However, when the temperature and humidity decreased to a specific range (mean annual temperature 2-12ºC, mean annual precipitation 200-700 mm) during the glacial period of L5, the fire occurrence reached its highest level.

Carbon cycle and carbon isotope fractionation during the snail assimilation process

xuefen SHENG[1]*, Nanjing University (shenxuer@nju.edu.cn)
Haolin TAN[2], Nanjing University

Abstract

Reconstruction of paleoclimate across different time scales is a hot topic in global change research. From long-term cyclical changes (such as glacial-interglacial periods, the Younger Dryas, Heinrich events, and the Little Ice Age) to short-term ones like seasonal variations and extreme weather events, paleoclimate studies across various time scales provide a research foundation for understanding the patterns and dynamics of global monsoon change. It also offers theoretical basis for climate models and future climate changes forecasting. Most existed climate proxies can only provide information for specific time scale, making it difficult to directly compare reconstructions at different temporal resolutions. Therefore, finding the proxies providing climate information across multiple time scales is important. Numerous studies have shown the potential of snail shells for reconstructing ancient vegetation and hydrology across different time scales. The δ13C and δ18O in snail shells can indicate changes in vegetation composition (precipitation) and precipitation δ18O over longer (climate) and seasonal (weather) time scales. However, the accuracy of interpretations regarding the climatic significance of shell δ13C and δ18O remains controversial. Therefore, this study conducts a systematic δ13C analysis of snail shells, soft bodies, and the organs through laboratory culturing experiments. The carbon isotope fractionation during snails' food intake, assimilation, and metabolic excretion processes is investigated. The results show a significant positive correlation between the δ13C in snail excrement and the δ13C in food organic matter. The δ13C in excrement fed with C3 plants is heavier relative to that of the food, while it is lighter when fed with C4 plants. This suggests that selective assimilation or/and different biochemical mechanisms when snail intakes plants of different photosynthetic types (C3 and C4plants). Snail mainly ingests organic matter from mixed feed, which is leading to an increase in carbonate content in excrement, which means the contribution of carbonate from food to shell δ13C cannot be directly calculated based on the ratio in food. The δ13C of different snail organs is significantly correlated with the δ13C of food and carbonate content. Organic and inorganic carbons from food affect the δ13C values of organs through different pathways, while organic carbon is mainly absorbed through digestion, while inorganic carbon is due to internal arginine synthesis after being converted to CO2 and entering the bicarbonate pool through acidification. There are significant δ13C differences between different organs, with the hepatopancreas is about 2% lighter than that of the kidneys, and the δ13C in foot is closed to that of the mantle. These results indicate that different organs and tissues in snails have varying turnover rates during metabolism, and the δ13C of different organ is related to its turnover rate, leading to isotopic fractionation difference during cell differentiation.

Combining with previous studies, this study further proposes the new mechanism for carbon cycle and isotope fractionation processes in snails.

Late Pleistocene and Holocene Landscape Evolution in the White River Badlands, Great Plains, USA

patrick albert burkhart[1]*, Slippery Rock University of PA (patrick.burkhart@sru.edu)

Abstract

The landscape of the White River Badlands (WRB), Great Plains, USA reveals geomorphic forcing upon pediments and dune fields at several intervals of time during the Late Pleistocene and Holocene. Radiocarbon dating of humic fractions of paleosols buried in pediments show that a regional incision of streams has dissected the pediments into sod tables within the recent two millennia. Two climatic events, the Medieval Climate Anomaly and the Little Ice Age are each a candidate for triggering stream incision and dissection of the fans capping the pediments. While numerous climate proxies indicate that the interior of North America endured megadroughts during these climatic events, the WRB themselves contain few proxy records. Recognizing this geomorphic impact propelled further inquiry into the response of dune fields within the WRB. These dunes are important paleoclimatic indicators in an area of the Great Plains with few climate proxies. Detailed topographical mapping with drones has guided morphological study of the dunes, coupled to the use of Optically Stimulated Luminescence to identify intervals of aeolian activity. The results show three periods of dune activity: (1) ~ 21,000 to 12,000 years ago, (2) ~9 to 6 ka, and (3) post 700 a. This latest event appears synchronous with the fluvial incision that characterizes the formation of sod tables from dissected pediments across the region. Results suggest significant landscape resilience to wind erosion, which resulted in preservation of a mosaic of Early and Late Holocene parabolic dunes. In contrast, ongoing fluvial incision of the prairie exhibits rapid erosion – aggressive incision of channels coupled to lateral retreat of slopes eroding into poorly indurated silts.

Integrated multi-geochemical analysis for reliable 14C age of artificial carbonates

Zhanpeng Chen[1]*, Nanjing University (502022290025@smail.nju.edu.cn)
Xufen Sheng[2], Nanjing University
Junfeng Ji[3], Nanjing University

Abstract

Artificial carbonates (AC) are a type of non-natural carbonate commonly found in archaeological sites, originating from the alteration of natural materials through human production and living activities. The formation process of these carbonates is controlled by the environmental conditions, with atmospheric CO2 being directly absorbed by calcium hydroxide. Therefore, these carbonates may record environmental information and have a significant potential in offering an insight into the climate shifts during ancient civilizations. Establishing an accurate age framework of AC is crucial for paleoclimate research. However, the 14C dating results of AC often present significant uncertainties due to factors such as the old carbon effect, differences in carbonation process, and secondary effects. This study carefully analyzed the mineral constituents, trace element ratios, stable isotopic compositions, and mineral morphology of AC collected from the archaeological city-walls of the Song and Ming-Qing dynasties, and further discussed their potential for 14C dating.

Based on multi-proxy geochemical analysis, we developed a sample selection method for 14C dating of AC. Initially, through the selective leaching with dilute acid and trace element ratios, there is a significant positive correlation between ln(Sr/Ca) and ln(Mg/Ca) in AC, which is following the Rayleigh fractionation model. This indicates continuous formation of carbonates from initial paleo-solution, exhibiting authigenic secondary characteristics. Authigenic secondary carbonates usually contain small amounts of Mg and Mn, with the associated Mg and Mn mainly derived from primary carbonates, i.e., geogenic carbonates that have not been combusted sufficiently, which can lead to the dating results being erroneously older. However, under extreme Rayleigh fractionation and secondary calcite precipitation conditions, the Mg/Ca ratio in soil solutions may increase, leading to lower Mn/Ca in AC and a negative correlation between Mn/Ca and Mg/Ca. Secondly, by selecting samples predominantly consisting of authigenic secondary carbonates and utilizing stable isotope analysis, we found that only the targeted collection of AC exhibited a general positive correlation between δ18Ocalcite and δ13Ccalcite, showing a relationship of δ18Ocalcite = 0.59δ13Ccalcite - 1.18(VPDB) and consistent with kinetic fractionation. Controlling factors such as diagenesis and the mixing of primary calcite could cause remarkable deviations in isotopic compositions. Eventually, to evaluate the impact of varying degrees of isotopic deviation on chronology analysis, we selected samples located at different positions along the kinetic fractionation line for AMS 14C dating. Results show that AC close to the kinetic fractionation line or contain extremely negative δ18Ocalcite and δ13Ccalcite typically have lower Sr/Ca and Mg/Ca, with minimal interference from primary carbonates. The 14C

chronology results largely match our expectations. Thus, selecting AC based on geochemical data can improve the accuracy of 14C dating, having broad prospects for application and promotion.

Abstract

Coral reef terraces (CRTs), normally observed along coastal areas and are formed through repeated bioconstructional and erosional processes, are useful indicators of relative sea-level changes in the past. Often considered as a process analog for predicted future changes for a warmer world is the Last Interglacial (LIG, also Marine Isotope Stage 5e) and the analysis of sea-level indicators during this period can give us important insights about potential drivers of local, regional, and global sea-level changes in the past. We previously produced a standardized database of LIG sea-level indicators in Southeast Asia. Following this work, we revisited Cape Bolinao, a site in western Philippines where inferred Late Pleistocene CRTs were previously reported. We present a newly revised record of relative sea-level changes for the region based on detailed analysis of digital elevation models (DEMs) and satellite images, high-resolution topographic surveys, stratigraphic and geochronologic analyses, and reef modeling. We identified distinct levels of CRTs (Terrace I to Terrace IX) which may correspond to different Marine Isotope Stages with the highest terrace, TIX, (at 143 ± 12 m amsl) inferred to be MIS 5e. Terrace IX is characterized by the presence of diagenetically altered corals (e.g., Porites, Platygyra) within a skeletal packstone matrix. We designated the lowest elevation terrace, TI, (at 3-4 m amsl) to be mid-Holocene based on C14 ages (~5.8-5.4 ka cal BP) and Th230 ages (~6.4-5.7 ka BP) of in situ corals. Two Tridacna spp. shells collected at 3-8 m amsl elevation yielded C14 ages of ~44 ka cal BP, which may correspond to MIS 3. We were not able to find pristine fossil coral samples at elevations of 5 to 160 m amsl as most are already diagenetically altered. We also conducted reef modelling to simulate the formation of the different levels of terraces with respect to chosen global sea-level curves. We found that with a constant uplift rate of 1.17 mm/yr, we will be able to

produce the staircase morphology we observe today with the highest terrace being formed during MIS 5e. We also observed that multiple terraces can be formed during one Marine Isotope Stage. Interestingly, using the sea level curve of Waelbroeck and others (2002), we were able to observe an MIS 3 terrace at 20-30 m amsl (which coincides to Terrace IV). Based on this work, we have provided evidence of mid-Holocene and older than Holocene terraces in the region and with our reef model, we were able to simulate the formation of these terraces during the different Marine Isotope Stages. While the analysis of CRTs is important in understanding relative sea-level changes in a region, the difficulty of finding dateable materials makes our work more challenging. Despite this, we hope that our data will be useful in further understanding the different drivers of past sea-level changes in SE Asia providing necessary geologic baseline data for projections of sea-level change in the future.

Hydroclimate changes during the Meghalayan Stage and its global teleconnection from Southern India

Upasana Swaroop BANERJI[1]*, Ministry of Earth Sciences (upasana.s.banerji@gmail.com)
Maya K[2], National Centre for Earth Sciences
D. Padmalal[3], National Centre for Earth Sciences
Kumar Batuk Joshi[4], National Centre for Earth Sciences

A.K. Sudheer[6], Physical Research Laboratory
Ravi Bhushan[7], Physical Research Laboratory

Abstract

The Meghalayan Stage (4.2 ka- Present), being the most recent interval of Earth's history provides an extensive amount of evidence for paleoclimate reconstruction and global climate teleconnection. Yet the significance of the Meghalayan Stage remains elusive due to limited investigation on latitudinal scale paleoclimate comparison and its association with global atmospheric circulation. The global atmospheric circulation has been the prime driving factor for the variability of the Indian Summer Monsoon (ISM) thereby impacting the climate and socioeconomic conditions of the Indian subcontinent. However, during the last few decades, the ambiguous changes in the ISM invoked the need to explore the centennial to millennial-scale past climate variability, especially during the Meghalayan stage, which has been observed as low-latitude aridification around 4.2 ka and resonated well with the archaeological evidence.

The ISM enters the Indian landmass through Kerala, southwestern India and gradually advances further causing rainfall throughout the country, thus, Kerala acts as a gateway for the ISM advancement thereby providing an ideal platform to investigate paleohydrological changes since the onset of the Meghalayan Stage. Considering the above, the present study aims to investigate the paleomonsoon variability during 3-5 ka demonstrating the onset of the Meghalayan Stage of the Holocene Epoch and addressing the linkage of ISM with the natural climate variables and forcings.

A sediment core of nearly 4 m in length raised from a Shasthamkotta freshwater lake was chronologically supported by six AMS radiocarbon dates studied using a multiproxy approach. The study demonstrated a dry climate (weak ISM) during 3.5-3.7 ka and 4.7-4.9 ka interrupted by a strong monsoon spell. Unlike the speleothem of Mawmluh Cave, Meghalaya (stratotype of Meghalayan Stage), the 4.2 ka severe arid event is merely observed in the present study, on the contrary, the monsoon intensification during 3.6-3.8 ka observed in the present study corroborated well with the speleothem of Mawmluh Cave.

The weak ISM periods (3.5-3.7 ka and 4.7-4.9 ka) resulted from low solar forcing while the 4.7-4.9 ka climate also witnessed enhanced El Nino events. An imperative role of Total Solar Irradiance (TSI) in controlling the ISM variability is envisaged with the possible occurrence of an El Nino event restricting ISM during 4.7-4.9 ka, and thereby triggering the 4.2 ka dry climate over the Indian subcontinent. However, the signals of 4.2 ka are seldom observed from the records of

the southern Indian lake. The study emphasises the association of ISM variability with the global forcing during the commencement of the Meghalayan Stage and invokes the need to identify the signals of 4.2 ka at different latitudinal scales.

Abstract

The coastal sediments in Kerala are preserved in two distinct geomorphological settings; in palaeo-mudflat/ coastal swamp deposits occurring inland, which are bordered by medium to fine sandy beach-ridge sequence, sub-parallel to the modern shore. While the palaeo-beach ridges generally devoid of shells, the equivalent ancient low energy tidal flats and coastal lagoon deposits show well preserved shells, mostly autochthonous. The study aims to understand the change in palaeo-environments using the abundance of species assemblage of shells in the sediments and radiocarbon and OSL dating to constrain the age of deposition. The samples were collected from five different locations of Thrissur district, Kerala, located 5-10 km inland from the present shoreline. The sections display lenticular bedding within the mudflat sediments and fossil shells where embedded in the grey sandy clay to clayey substratum at variable depth (between 2-10.5m). The taxonomic compilation of the shells shows that the specimens largely composed of bivalves and gastropods in the invertebrate macro-fauna with their characteristic environment of occurrence ranging between marine, marginal marine and estuarine conditions. Radiocarbon ages constrain the timing of distinct periods of shell accumulation during 6870±220, 7080±200, 3350 ±160 yrs. BP and >40 ka BP. The OSL dating of clastic sediments of younger beach ridge sequence bordering the lagoons/ mudflats largely show age of deposition between 0.5±0.1 ka and 4.0±0.1 ka. The sand units from the palaeo mudflat units at varying depth between 4.6m to 9.2m had shown age of deposition between 40.0±2.0 ka and 55.0±2.0 ka. The shell deposit displays an abundance of well-preserved Holocene shell specimens and slightly altered shells due to the effect of differential taphonomic conditions during late Pleistocene. The marine influence in the species assemblage and the formation of these landforms as a consequence of late-quaternary sea-level fluctuations at distinct time period and associated environmental response is deduced.

Variability of leaf wax n-alkanes across gradients of environment and plant functional type in China

Yutao ZHOU[1]*, China Agricultural University (zhouyt@cau.edu.cn)
Guoan Wang[2], China Agricultural University
Yaowen HAN[3], China Agricultural University

Abstract

The abundance and distribution of long-chain n-alkanes in sedimentary archives have been proposed as plant-derived paleoenvironmental proxies. The reliable application of these proxies hinges on comprehensive understandings drawn from investigations of living plants. However, previous studies have predominantly relied on a limited dataset sourced from local and regional sampling. As a result, our comprehension of how n-alkanes in living plants respond to climate factors on larger spatial scales remains unclear, especially across different Plant Functional Types (PFTs). In this study, we analyzed the abundance and distribution of n-alkanes in the leaves of 552 plants from diverse regions in China and explored the variability of leaf wax n-alkanes across gradients of climate and PFTs. We found that (i) the average chain length (ACL) and carbon preference index (CPI) exhibit statistically significant differences between various PFTs, although these differences may not be substantial enough to reliably distinguish between PFTs, (ii) the ratio of C33/(C31 +C33), C33/(C29+C31 +C33) or C33/ΣoddC27-33 exhibit considerable discrepancy between C3 herbs and C4 herbs, as well as C3 plants and C4 plants. (iii) the variance in n-alkane concentration (Σalk) is primarily controlled by precipitation, with a notable negative correlation between Σalk and mean annual precipitation (MAP) that is independent of PFTs, (iv) CPI demonstrates a weak correlation with climate factors, and (v) ACL shows a positive correlation with mean annual temperature (MAT) and a negative correlation with MAP. MAT appears to be a stronger driver of ACL for C4 herbs and woody plants, while MAP exerts a more pronounced influence on C3 herbs. These findings indicate that ACL and CPI are not effective in distinguishing between PFTs. However, the ratio of C33/(C31 +C33), C33/(C29+C31 +C33) or C33/ΣoddC27-33 hold the potential to distinguish between C3 and C4 vegetation types. Σalk is a good indicator of precipitation, while ACL can serve as an indicator of either precipitation or temperature, depending on the specific PFT. In contrast, CPI appears generally insensitive to climate, and great caution should be exercised in using CPI records in paleoclimate research.

Last and Holocene interglacial relative sea-level rises and coastal sedimentation in the Korean Peninsula

Woo Hun RYANG[1]*, Jeonbuk National University (ryang@jbnu.ac.kr)
Hyun Ho Yoon[2], Korea Institute of Geoscience and Mineral Resources (KIGAM)

Abstract

During the last interglacial (LIG), known as Marine Isotope Stage (MIS) 5e (about 130 to 115 ka), global sea level was 5~9 m higher than present sea level. However, the apparent magnitude of that highstand is expressed differently across the globe depending on local tectonics, glacial-isostatic adjustment processes, and sediment compaction. Like most of the world's coastlines, the Korean Peninsula experienced higher-than-present sea levels during LIG. The expression of that highstand in the geological record differs across the eastern and western Korean Peninsula. A total of 62 LIG constraining data points were compiled including 34 sea-level indicators, 22 marine limiting records, and 6 terrestrial limiting records. The ages from these data points are based on 61 optically stimulated luminescence (OSL) measurements and 1 paleomagnetic-based age. The tectonically active east coast of the Korean Peninsula is characterized by broad uplifted marine terraces, while the stable west coast is characterized by tidal flats and rias. Tectonic uplift likely has affected the elevations of the east coast LIG shorelines, while LIG sea-level records on the west coast of the Korean Peninsula are found at heights of between +3 and +6 m. In the macrotidal Gochang coasts of southwestern Korea, a transition from lower heterogeneous muddy tidal-flat deposits to upper sandy tidal-beach deposits occurred during the Holocene interglacial. The open-coast shelf experienced decreasing rates of Holocene sea-level rise, and 14 OSL ages from a single 32-m-long core track decreasing rates of the RSL rise during the Holocene. As the rate of sea-level rise decreased, a tide-dominated depositional process switched to a wave-dominated one during the late stage of transgression. Decreasing rates of RSL rise during the Holocene interglacial, accompanying changes in the underlying sea-floor bathymetry, can drive a switch from a tide-dominated tidal flat to an open-coast tidal flat and ultimately a wave-dominated tidal beach through time.

New Geochronological Data on the Tatun Volcano Group in Northern Taiwan

Su-Chin CHANG[1]*, The University of Hong Kong (suchin@hku.hk)
Mei-Fei Chu[2], National Taiwan University

Abstract

The Tatun Volcano Group (TVG) is located at the northern end of Taiwan, adjacent to Taipei, a city of two million inhabitants and a metropolitan area of over seven million. This volcano group forms the core of the Yangmingshan National Park, one of Taiwan's most popular tourist destinations. Previous age studies proposed that the TVG eruptions with lava flows ceased at ~0.2 Ma, while emerging seismic and isotopic data indicated an active magma reservoir beneath. Over the past 20 years, vigorous debate has considered whether its eruption history based on old geochronologic data is accurate. In this study, we report novel 40Ar/39Ar ages for two andesite samples and one basalt sample from TVG outcrops. The sample collected from Chihsingshan, the highest mountain in the area, yielded a robust age of 81 ± 5 ka. Two samples yielded 0.28 ± 0.02 Ma for Tatunshan and 0.159 ± 0.017 Ma for Honglushan. Our new geochronological data update the previously proposed age model for the TVG, improving our understanding of the tectonic setting of the Northern Taiwan Volcanic Zone. Furthermore, our study suggests a mitigation plan must be developed to prevent the primary and cascading effects of volcanic hazards, as any future volcanic activity may impact Taiwan and the nearby areas.

A modern pollen-climate dataset from South Korea for palaeoclimate reconstruction

Jaeyoung LEE[1]*, Korea National University of Science and Technology
(jaeyounglee@kigam.re.kr)
Sangheon Yi[2], Korea National University of Science and Technology

Abstract

The occurrence of extreme weather events in response to climate change has become a global concern. To prepare for the intensifying climate crisis, it is imperative to comprehend past extreme climate fluctuations, control factors, and triggers. In this study, we conducted a pollen-based quantitative reconstruction of the Northeast Asia paleo-climate. We collected 387 surface soil samples from 89 mountains in South Korea to produce a modern pollen assemblage dataset. The dominant taxa were P. subgen. Diploxylon and Q. subgen. Lepidobalanopsis, which showed a tendency to increase and decrease in contrasting patterns. Abies, Betula, and Picea were mainly collected at high altitudes, and Tann was low while Pann and Psum were high. Quercus subgen. Cyclobalanopsis and Alnus were mainly found in the southern region or low-altitude mountainous regions. This finding was similar to vegetation patterns in South Korea and the Korean Peninsula's fossil pollen assemblage during the Holocene. NAP was rare compared to AP among our samples, and NAP showed weaker intercorrelations than AP with climate variables in South Korea. As the dataset indicated that pollen samples from South Korea reflected the regional vegetation well, we applied a weighted modern pollen analogue technique to quantitatively reconstruct the mean annual temperature (Tann), annual precipitation (Pann), and summer precipitation (Psum) in the Gwangyang area. The reconstructed Tann increased by ca. 4000 cal BP and gradually decreased thereafter. Long-term Tann trends in the Gwangyang area, along the East Asian continental and Northwestern Pacific margins, appear to have been influenced by oceanic climate conditions, particularly the Kuroshio Current, whereas short-term trends were significantly correlated with the continental climate, the East Asian winter monsoon, and Bond events. Pann and Psum have gradually decreased during the Holocene, which is consistent with the induction of the East Asian summer monsoon by a northward shift of the Intertropical Convergence Zone. After ca. 5000 cal yr BP, the decrease in Pann slowed in association with strong typhoon activity of the El Niño–Southern Oscillation. Analysis of hydroclimate proxy data from southern South Korea revealed wet events at ca. 8900, 7800, 5900, 4500, 3200, 1900, and 1300 cal yr BP, and dry events at ca. 9300, 8200, 6200, 5200, 2800, 2200, and 1400 cal yr BP. Notably, we also confirmed the occurrence of a flooding event in southern South Korea at ca. 8900 cal yr BP.

Surface microtextures of quartz grains in soil of Chuncheon Basin

Eun-chae SHIN[1]*, Department of Geology, College of Natural Science, Kangwon National University (KNU) (eun@kangwon.ac.kr)
Kyoung-nam Jo[2], Department of Geology, College of Natural Science, Kangwon National University (KNU)

Abstract

Quartz is the most abundant mineral in the soil. Additionally, it exhibits strong resistance to chemical and mechanical weathering compared to other rock-forming minerals. However, traces of transportation and sedimentation processes leave microtextures on the surface of quartz grains. These characteristics serve as useful indicators of the environment. Furthermore, analyzing the surface of quartz grains using SEM is useful for understanding the formation of sediment and the contemporary weathering and sedimentation environment. In this study, the surface microtextures of quartz grains (SMQ) in soil originating from Chuncheon granite were investigated, considering the climate conditions of Chuncheon City, Gangwon-do, on the Korean Peninsula. Furthermore, a factor analysis was conducted to interpret how soilization and weathering processes influence the characteristics of SMQ. The overall properties of soil SMQ in the Chuncheon area include some predominant physical microtextures, such as angular outlines, large/medium/small conchoidal fractures, arcuate/straight steps, and upturned plates. Additionally, there are chemical microtextures resulting from dissolution/sedimentation within diagenetic alteration environments. One of the main characteristics of soil SMQ is the presence of physical microtextures well-known to be formed through freeze-thaw processes, such as breakage blocks and microsteps. Another characteristic of SMQ in the study area is that quartz grains with original crystal planes are more frequently observed in the outer basin soil than in the inner basin soil. This observation indicates the degree of weathering based on the distance from the center of the basin because the original crystal planes signify properties authigenically originating from the host rock. Another noteworthy point is that, in the same soil profile, SMQ of the B horizon shows a dominant frequency of silica globules, silica flowers, and silica pellicle than the A horizon. Through these results, the water content changes in accordance with the depth from the surface, playing an important role in the formation of surface microtextures due to precipitation on the surface of quartz grains. Factor analysis was conducted using SMQ results. Factor 1 represents the climate conditions of the study area, which have the most significant impact on the microtexture of quartz grain surfaces in the soil environment. Factor 2 represents the residence time of quartz grain. The results of this study may contribute to the systematization and further research using SMQ data for various environments in the Korean Peninsula.

The preliminary study of reconstructing abrupt climate shift with speleothem in Korean Peninsula: a textural approach

Jungwon CHOI[1]*, Department of Geology, College of Natural Science, Kangwon National University (KNU) (eplchoi@kangwon.ac.kr)
Kyoung-nam Jo[2], Department of Geology, College of Natural Science, Kangwon National University (KNU)

Abstract

Abrupt climate transition is well documented in the Greenland ice core and other various archives. Several records from Chinese speleothem suggest that D-O events possibly affect on monsoon intensity and therefore climate conditions in the EASM area. In this study, age dating and textural analysis are performed on the lower part of JM2 stalagmite, which grew during the Pleistocene. This study aims to investigate possible textural responses to abrupt climate shifts.

16 points of 230Th age dating results suggest that the lower part of JM2 grew in Late Pleistocene, from 79,219±133 to 58,233±118 yr BP with an average error range of ±164.38. According to the age dating result, the growth period of JM2 includes the D-O 20, 19, 17, 16, 15 14, and MIS 4 to 5 boundaries. Therefore, it is possible that textural and geochemical evidence of each event can exist.

The textural analysis is divided into three processes. 1) Macro-scale observation, 2) Microscopic observation. Three significant tilting events in the growth axis are recognized and divided JM2 into three phases. Phase 1 can be described with Seven sub-phases with relatively stable growth axis. In contrast, phase 2 and 3 exhibit an abrupt tilt of the axis, result an unclear texture. At the distal texture of phase 3, a major hiatus was recognized with texture and age models. A microscopic investigation reveals that the fabrics of lower JM2 are showing compact and open calcite fabrics. The width of columnar calcite varies from narrow (90.72μm avg.) and thick (338.22 μm avg.).

Based on the age model and textural analysis, it appears that two condensed laminae coincide abrupt warming event, around the D-O 20 and 19. Laminae thickness measurement shows a similar trend with NGRIP and each interstadials.

This study provides insight of the paleoclimate in late Pleistocene. However, further detailed studies are required.

Abstract

The sedimentary infill of glacially overdeepened valleys can serve as an excellent archive of the landscape evolution in formerly glaciated areas. The first phase of the ICDP (International Continental Scientific Drilling Program) project DOVE (Drilling Overdeepened Alpine Valleys) is investigating several drill-cores from overdeepened valleys along the northern side of the European Alps and their foreland. One of the investigated sites (ICDP-5068-5) is located in an inner-alpine setting near Bad Aussee (Austria), where a distinct gravity anomaly was initially interpreted to be caused by a large salt body. A subsequent drilling, which did not reach the bedrock, instead revealed an astonishing 880-m-long succession consisting of (glacio-)lacustrine and fluvial sediments under a thick cover of subglacial till. Results from luminescence dating show that the drilled sequence spans at least the last two glacial cycles. Petrographic and mineralogical analyses indicate highly variable sediment provenance, tentatively interpreted as a result of changes in the regional drainage network due to the effects of glacial landscape modification.

One of the major open questions concerns the effect of the regionally widespread evaporite rocks in the formation of this extraordinary overdeepened structure. As the drilled sediments are similar in density compared to salt, it is not possible to distinguish between these lithologies based on gravity data alone. Existing seismic data and the surrounding surface geology indicate the presence of evaporites in the close vicinity of the drill site. Through ongoing work combining gravimetry with electrical resistivity tomography and a high-resolution seismic survey, we aim to create a 3D geological model of the area to better understand the shape and internal architecture of

the overdeepening.
In this contribution, we give an outline of this multi-method approach and present preliminary results from the geophysical investigations. The results from sedimentological drill-core analyses enhance our understanding of Pleistocene landscape evolution in the Eastern Alps, where comparable records are scarce.

Millennial to seasonal trace element variability within stalagmite fluorescence banding during the Last Interglacial

Jihye KIM[1]*, Kangwon National University (rlacl9243@kangwon.ac.kr)
Kyoung-Nam Jo[2], Kangwon National University

Abstract

Seasonally variable conditions, such as monsoon climate can affect the fluorescence signal and also geochemical concentration of cave drip water, which allow speleothems to record annual paleoclimate signatures for the cave site. It has been suggested that fluorescence properties in speleothems is influenced by the presence of soil-derived soluble organic matter in infiltrated water after heavy rainfall. However, the fluorescence properties of speleothems from Korean caves have not yet been examined in detail. In this study, we use the stalagmite (OG1) collected from a cave located in South Korea, which shows fast growth during the last interglacial. We investigate the relationship between fluorescence banding and trace element variations, in order to explore its fluorescence properties and paleoclimatic significance. Fluorescence imaging of the stalagmite was taken by Confocal Laser Scanning Microscope (CLSM) and trace element concentrations were measured using an inductively coupled plasma mass spectrometer combined with a laser ablation system (LA-ICP-MS).

The stalagmite OG1 exhibits distinct annual lamination consisting of a growth line and growth band. The upper and lower parts of OG1 have different fluorescence properties showing gradual change in middle part. Interestingly, in the middle of OG1, there is a very thin dark growth line in the center of the fluorescence banding. However, in the upper part, the dark growth line is not visible on both optical microscopy and CLSM due to the thinner growth line but instead appears as a thin fluorescence band. This means that there may be textural change or incorporation of non-luminescent matter into crystal lattice during the growth line formation. The element contents in OG1 show annual fluctuations in Sr, Mg, Y, P, and REE compositions, which are very strongly related to the fluorescence banding. P, Y, and La concentrations peaked simultaneously with the lowest values in Sr, Ba, and Mg on bright fluorescence in the upper part of OG1. This suggests that the annual fluorescence band may be caused by input of large amount of water discharge during the rainy season. These results will be compared to the fluorescence properties and trace element content in the lower part of OG1 which has a different pattern to confirm the longer-term change during the last interglacial maximum.

Paleoenvironmental evolution since the late Quaternary from core YZ02 in the South Yellow Sea

XIA LIAO[1]*, Nanjing Normal University (liaoxia_2061@163.com)
PING WANG[2], Nanjing Normal University
YONG YIN[3], Nanjing University
LING ZHANG[4], Nanjing University
BO YANG[5], Nanjing University
Xiaoan LI[6], Nanjing University

Abstract

The South Yellow Sea (SYS) is a shallow (less than 100 m in water depth) epicontinental sea between the Korean peninsula and China. It underwent periodical subaerial exposure since the late Quaternary due to glacial-interglacial cycles, and was fully exposed during the LGM when the sea level was lowered by about 120 m below the present. Therefore, the sedimentary sequences of the SYS may provide significant records for paleoenvironment evolution during the late Quaternary in East Asia. Over the last two decades, numerous researches have been done in order to reveal the stratigraphic framework and paleoenvironmental evolution. However, there is still very few long sequences with reliable chronological frameworks from the offshore area. Here, we report new results of paleomagnetism, magnetic susceptibility and geochemical elements from a long-drilled core, YZ02, which is 80.1m in length with water depth of 56.8 m. Our magnetostratigraphic result reveals samples are all in Brunhes chrons, and indicates the age of the sediments no earlier than Marine Isotope Stage (MIS) 6. Based on sedimentary facies analysis, the core is generally dominated by fluvial deposition in MIS6 and MIS 2, shallow marine deposition in MIS5, MIS3 and MIS1 while no deposition during MIS4. The geochemical result shows that the ratios of Zr/Rb and Sr/Rb are relatively high while K/Ti is relatively low during MIS6 and MIS4. These element ratios reflect a cold and dry climate with less precipitation, indicating the strengthening of winter monsoon in the source region. Furthermore, the magnetic susceptibility shows a high value in the fluvial deposits of MIS 6 and an upward-decreasing trend, which may also reflect the large input of magnetic minerals for the source region during the dry climate.

Monsoon Mysteries Unveiled: Traversing Millennia Through Climate Reconstructions in Southern India

HEMA ACHYUTHAN[1]*, Centre for Environmental Studies, Anna University, Chennai 600025 (hachyuthan0@gmail.com)

Abstract

Reconstructing paleoclimates using current meteorological data is crucial for predicting future climate patterns and identifying any significant fluctuations. However, it is important to consider several caveats when utilizing proxy data generated through radiometric dating, tree-ring analysis, corals, cave deposits, soils, and lake and marine records for paleoclimate reconstructions. This study focuses on reconstructing Southwest Monsoon (SWM) variability employing lake sediments, cave stalactites, stalagmites, and 18O records from both Northern and Southern India. The findings illuminate climatic changes spanning millennia. Noteworthy is a substantial decline in monsoon strength around 1500 and 800-450 cal years BP, aligning with the transition from the Medieval Warm Period (MWP) to the Little Ice Age (LIA). From the LIA to the present, an uptick in droughts and floods is evident. Despite substantial variations in monsoon strength, no major shifts in its source, extent, and seasonality occurred before 2500 years BP. However, two brief arid phases occurred around 3500 and 2600 cal years BP, disrupting the otherwise stable SWM pattern. The Roman Warm Period (RWP) from 2100 to 1800 cal years BP witnessed a sharp monsoon decrease. In the Himalayan region, both dry and wet phases at the LIA's onset and end contribute regional nuances to broader monsoon variability. Corroborative evidence from lake and marine sediment cores in SWM-influenced regions, such as lakes Vellayani and Pookode in Kerala and from Landfall Island, Bay of Bengal, supports these findings. Radiocarbon dating of lake sediments spanning from 6240 to 565 14C BP reveals climatic shifts: drier conditions up to 3000 years BP and increased wetness around 1210 years BP. Lake sediment analyses, encompassing texture, Chemical Weathering Index values, phytolith and pollen assemblages, uncover warm and dry conditions during 6200–420 14C years BP (BC 4786–AD 1434 cal.). Intermittent wet phases around ∼3900–∼1900, ∼1400–∼760, and ∼420–∼140 14C years BP cause significant lake hydrological changes. Critical periods during the MWP and LIA witness a substantial shift in lake conditions. A decline in vegetation cover, evidenced by low phytolith morph types for 2300 years BP, is attributed to climate warming, weakened SWM, deforestation, and lake-margin reclamation for intensive agriculture. Strengthened SWM leads to short-wet events, elevating water levels and briefly expanding lake margins. Charcoal pieces post 3000 years BP indicate human impact. Marine sediment core, with radiocarbon ages from 6,078 to 1,658 years BP, display grain size variations reflecting cyclic wetter and drier conditions, aligning with SWM intensity shifts. Higher CaCO3 content, εNd, and 18O in Globigerinoides ruber affirm a long-term trend from cooler, wetter conditions to warmer, drier conditions. CWI reveals highly weathered sediment deposited around 4,000 years BP. Smectite and chlorite/illite (C/I) variations signifies an overall SWM weakening from 6,000 to 2,000 years BP, with an extremely reduced

SWM around 4,400 to 4,200 years BP. Oxygen isotope data on G. ruber indicate a major shift ~4,300 years BP, indicating a weakened SWM. Fluctuations in SWM intensity from the past 2,000 years to the present highlight the dynamic nature of monsoon patterns in the region.

Reconstruction of Holocene Climatic Dynamics in the Western Himalaya: Speleothem Record

Jaishri Sanwal BHATT[1]*, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore (jaishrigeology@gmail.com)
Vinod Chandra Tewari[2], Formerly,Geology Department,Sikkim,Central University,Gangtok - 747201, Sikkim ,India

Abstract

The climate in the western Himalaya, shaped by the intricate dynamics of the Indian Summer Monsoon (ISM) and Western Disturbances (WDs), replenishes glaciers and plays a pivotal role in water security and agriculture. The geographical and physiographical distinctiveness of this region offers an excellent natural laboratory to reconstruct the dynamics of paleo-monsoon by using terrestrial proxies. This study reconstructs the climatic variations over ~4000 years using a U/Th-dated speleothem from Sweel Cave, Himachal Pradesh, Western Himalaya. We analyzed stable isotopes and trace elements distribution along the maximum growth axis of a speleothem that was actively growing during the collection in 2020. The variations in Mg/Ca and Sr/Ca ratios align with stable isotope records. Our results suggest substantial precipitation between ~4000 to ~3700 yr BP and ~3350 to ~3200 yr BP, evident by the gradual decrease in δ18O. Two phases of low precipitation are observed between ~3650 to ~3300 yr BP and ~3400 to ~3000 yr BP. A substantial increase in speleothem growth is seen after 3000 yr BP until ~2800 yr BP, followed by a brief drier phase. A fluctuating trend in δ18O suggests heavy rainfall after 2700 yr BP and a gradual decrease in precipitation between ~2400 to ~2100 yr BP. The increased precipitation, aligning with Mg2+ incorporation, δ13C, and δ18O values provide evidence of substantial climatic shifts ~1800 to ~1570 yr BP. Reduced precipitation between 1,445 to 1,411 yr BP with a declining trend of δ18O (-5.91‰ to -5.60‰) and δ13C (-7.10‰ to -6.83‰) coupled with an abrupt increase in Mg/Ca ratio and a decrease in Sr/Ca. A gradual decrease in Mg, corresponding to negative values of δ18O (-6.67‰ to -6.52‰) and δ13C (-8.22‰ to -7.33‰), provide strong evidence of substantial precipitation around the cave during ~1,319 to ~1,025 yr BP. The monsoonal behaviour over the last 1000 years portrays dramatic shifts characterized by recurrent natural disasters impacting human populations. The Medieval Warm Period (MWP) and the Little Ice Age (LIA), exhibit globally recognized weak and robust monsoon cycles. Our results show multi-decadal weak-monsoon periods between ~930 to ~850 and ~800 to ~570 yr BP. The strong ISM during the MWP correlates with the warm water circulation, generating a pressure gradient between the Indian Ocean and the Eurasian continent. Our study reveals intensified monsoons during the onset of the LIA between ~570 to ~290 and ~270 to ~130 yr BP. ISM intensity during the LIA exhibits significant heterogeneity, showcasing a low precipitation trend over peninsular India and increased monsoon precipitation in northern regions, which may be attributed to the 'break event" and winter westerlies. Simulation modelling suggests the migration of ITCZ from the Bay of Bengal to the Arabian Sea, influenced by solar insolation, impacting precipitation in

the monsoon zone and Himalaya during the mid-late Holocene. We noted a decreasing rainfall trend post-1880 CE, particularly pronounced from 1980 to 2019 CE. This aligns with cave drip water isotopic signatures in two ongoing monitored Himalayan caves in western (Sweel) and central (Sauli) Himalaya, signalling a recent decline in WDs.

[Keynote] Holocene Meghalayan Stage Speleothem (Stalagmite) carbonate petrography and paleoenvironmental significance from Meghalayan and Lesser Himalayan caves, India

VINOD CHANDRA TEWARI[1]*, Professor of Geology (Retd.), Sikkim University, Gangtok – 737102, Sikkim, India (Professorvct54@gmail.com)

Abstract

The latest Holocene Meghalayan Stage (4200 years) has been recently established from a well developed stalagmite from Mawmluh cave in Meghalaya, Shillong Plateau,NE India.There are several Holocene caves in other parts of the Meghalaya in northeast and northwestern regions of the Lesser Himalaya, India.The high resolution regional climate variation based on oxygen isotopic pattern from northwest to northeast needs further support from other physico-chemical,carbonate mineralogical and sedimentological proxies during the meteoric precipitation. Speleothems are continental cave deposits of carbonate minerals formed due to dissolution of the host rock, and its re-deposition in caves due to degassing of CO2.Speleothems are widely used as most reliable archives of continental palaeo- environment because of their depositional continuity, no diagenetic imprints,accurate chronology through U-Th disequilibrium series dating, high temporal resolution and wide spatial distribution.Stable isotopic changes from the speleothem carbonates of the Meghalayan and Lesser Himalayan caves of India reveal information about the meteoric precipitation during its formation and the regional climate conditions.Systematic petrographic studies of speleothem microcrystalline fabrics can explain the exact conditions of paleoenvironment during speleothem growth. Columnar calcite is usually common during wet conditions. In the present study, stalagmites from the Mawmluh, Meghalayan type area ,Mastos and Labit caves have been studied mineralogically, petrographically and geomicrobiologically.In addition to this, Sahastradhara, Prakateshwar and Chulerasim caves also situated in core Monsoon region in western Lesser Himalaya in Garhwal-Kumaon regions of Uttarakhand Lesser Himalaya have been investigated. Calcium carbonate speleothems dominate most of the caves globally.The petrographic studies show significant variations in calcite fabrics during wet and dry periods.Columnar crystals are observed in wet periods but other radiaxial ,dendritic and microstromatolitic micro fabrics were formed during different hydrological and paleoenvironmental conditions.The Mg rich radiaxial fabric of acicular crystals usually develop in drier conditions.Filamentous bacteria dominate cave microbial mats in Meghalaya.Bacterial association with carbonate minerals is quite significant in establishing the biomineralization process (interaction of microbes with calcite, aragonite and dolomite).Recent petrographic, Scanning Electron Microscopy , Cathodoluminescence and Laser Raman Spectroscopic studies of filamentous bacteria and microbially laminated structures (microstromatolites) from Meghalayan and Sahastradhara caves have confirmed the contribution of microbes to calcium carbonate precipitation in stalagmites.Geomicrobiology is an emerging field of research and grown over the last fifteen years research on speleothems from Indian caves and other parts of the world.`

The comparison and correlation between the petrographic microfacies changes, their relationship with stable isotopic data, major and trace element variation, and geomicrobiological evidences from these very significant speleothems (stalagmites) from Meghalaya and Lesser Himalaya situated in two different monsoon dominated regions of India has been discussed.Speleothems in Central Nepal Pokhara valley also shows regional Holocene Indian Summer Monsoon activity in South Asia between northern India and south of Himalaya.

Comparison between a stalagmite record and a peat record over the past 14 Ka from NE China: To what extend the proxies in stalagmite and peat records to reflect climate changes

Hong-Chun Li[1]*, National Taiwan University (hcli1960@ntu.edu.tw)

Abstract

A 21.5-cm long stalagmite (20170710-4S) from Yunxia Cave in Tonghua City, Jilin Province was dated by 230Th/U and analyzed for d18O and d13C in 2500 subsamples. The high-resolution record exhibits detailed climate and vegetation variations from 11.7 Ka to the present. A 8.5-m long peat core (HNB) retrieved from Hani peatland in Jingyu County, Jilin Province was dated by 14C dating (a total of 105 14C ages) and measured for H2O%, dry bulk density (DBD), total organic carbon (TOC) and ash (%) on 850 subsamples. HNB contains the record from 14.1 Ka to the present. The two studied locations are about 80 km apart in the NE China where the climate is influenced by the east Asian summer monsoon as well as westerly, so that they should reflect the same climatic setting and allow us to compare the proxies in each records for climatic interpretations. The 4S d18O and d13C records exhibit centennial cycles superposed on multi-millennial trends. Between 8 and 3.5 Ka, both d18O and d13C were lighter than their averages, whereas between 3.5 Ka and the present the d18O and d13C were heavier than the averages. Before 8 Ka, the d18O and d13C were fluctuated around the averages. These multi-millennial trends of d18O and d13C during the middle and late Holocene may reflect long-term shift of moisture source and vegetation type related to summer monsoonal strength. Thus, it is necessary to make de-trend in the d18O and d13C records. The de-trended d18O and d13C provide centennial variations in terms of wetness, being the negative Dd18O and Dd13C values reflecting wet climatic condition, and vice versa. The peat record, on the other hand, showed stable high TOC and low recent carbon accumulation (RCA = TOC*DBD* SR (sedimentation rate)) during 3.5~8 Ka, but strongly centennial variations before and after this period. RCA is strongly positively correlated with SR (R2 = 0.85), but weakly related with TOC and DBD. The latter two have negatively correlation (R2 >0.6). The comparison of the stalagmite Dd18O and Dd13C with the peat TOC and RCA reveals that the negative Dd18O and Dd13C periods representing wet period generally corresponding to low RCA, and vice versa. This means that the peat development is better during relatively cold and dry conditions under weak summer monsoon. Two explanations may be considered: 1. Flooding and elevated water table under warm and wet conditions are not in favor of moss development in peatland. 2. Detritus input under warm and wet conditions could reduce SR and TOC. When DBS is greater than 0.25 g/cm3 and TOC is less than 20%, the RCA is strongly influenced by detritus and does not reflect peat development. Therefore, one should not depend on solely RCA or TOC of peat record for climatic interpretation. With the detailed stalagmite and peat records, we are able to interpret the monsoonal climates in the study area.

Signatures of trace element variations in the Indian speleothem from the core monsoon zone during the late Holocene

Naveen GANDHI[1]*, Indian Institute of Tropical Meteorology, Pune (naveen@tropmet.res.in)
Ipsita Roy[2], Indian Institute of Tropical Meteorology, Pune
Damodararao Karri[3], Indian Institute of Tropical Meteorology, Pune

Abstract

Speleothem trace elements serve as valuable proxies for investigating past precipitation changes in tropical areas at an annual to decadal time resolution. While elemental variations in biogenic carbonates have been extensively studied, speleothems have received less attention in this regard. The core monsoon zone of the Indian subcontinent is crucial for analyzing past fluctuations in the Indian summer monsoon. A speleothem from the Gupteswar cave in Odisha, India, collected and dated using the 230Th/234U method, covers the last 3000 years. Trace elements, including Mg, Ba, Sr, Mn, U, and Rb were analyzed to understand regional and local climate variability induced by the Indian Summer Monsoon. This cave lies in the core monsoon zone of the Indian subcontinent and receives approximately 1,500 mm of rainfall annually. Over the past 3000 years, warm and moist climates were documented during the Roman Warm Period and the Medieval Warm Period, while relatively dry conditions were experienced globally around 2.8 ka and during the Little Ice Age. Overall, trace element behavior in speleothems is influenced by regional climate, seepage pathway, bedrock chemistry, and vegetation cover above the cave. A shift in Mg, Ba, U, and/or Ba to Sr ratios indicates a change in the intensity of regional precipitation or local moisture availability. The Mn concentration correlates with the contribution of the element from surrounding vegetation. Additionally, the Rb to Sr ratio is postulated to represent the depositional behavior of sediments at the study site. Trace element variations in the speleothem capture short-lived and abrupt climatic events. The trace elemental variations driven by climatic events and the possible driving mechanisms will be presented at the conference.

Abstract:
The Indian Subcontinent in South Asia has a history of civilization that can be traced back to 5000 years from present and boasts a geological history of 3.5 billion years and also recently established the youngest Holocene age of Earth history from the isotopic dating of speleothem (4200 years old stalagmite) from limestone cave of Meghalaya given the name Meghalayan Stage. The Indian Summer Monsoon (ISM) is a very significant phenomenon throughout Asia and the Indian subcontinent. The livelihood of the billions of people living in this region primarily depends on agriculture and consequently on ISM. ISM controls the climate of the South Asian region and has affected the civilization due to severe drought conditions in the past that is why ISM's precipitation patterns are being reconstructed using speleothems (mineral deposits in cave formed by the calcium carbonate precipitation due to dripping groundwater) to study those past events. The detailed study of the speleothems mainly stalagmites is quite significant in dating and establishing the intensity and abrupt change in the monsoonal conditions by measuring the oxygen isotope ratios of the stalagmites. The recently established “Meghalayan Stage” of Holocene epoch has been dated 4200 years from a stalagmite of the Mawmluh cave in Shillong Plateau, Meghalaya, Northeast India. There are hundreds of caves very well preserved and found extremely useful in the study of paleoclimate, paleomonsoon and historical events associated with abrupt change in societal conditions due to climate change. In northeast India, the largest caves are developed in Meghalaya around the town of Cherrapunji (Sohra,Mawsmai, Mawsynram,Mawmluh and Mustos caves) where the heaviest monsoon rainfall in the world is recorded. The stalagmites from these caves have given important traces about the intensity of the ISM in the past, abrupt change in monsoon conditions since pre historic time and now they are well dated by the uranium series technique and oxygen stable isotope variation since stalagmite

records have the ability to predict future changes in the ISM as well. The tremendous progress gained in this area recently suggests global research opportunities in the future for young researchers. The evidences of paleoclimatic glacial event of Little Ice Age (LIA), intensity of ISM establishedby oxygen isotope ratios from stalagmites from Meghalayan Stage (Mawmluh and other caves) has been discussed.

Seismic Impact on Speleothems and Cave Structures: Evidence for Major Earthquakes in the Central Himalaya

Jaishri Sanwal BHATT[1]*, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore (jaishrigeology@gmail.com)
Rajendran CP[2], National Institute of Advanced Studies, Bangalore

Abstract

The investigation of structural damage and growth anomalies in speleothems in the Central Himalaya holds the potential for accurately dating the earthquake-induced impacts in and around the caves. These formations, which include stalagmites, stalactites, and soda straws that exhibit breakage in alignment with the cave roof, provide valuable insights into seismic events. This work delves into active fault structures and geomorphic features in and around caves, providing chronological constraints linked to earthquakes. Using six deformed stalagmites from four limestone caverns - Sweel, Bhuligao, Dharamjali, and Hathikhal caves in the central Himalaya, we aim to establish timings associated with paleo-earthquakes affecting the caves and the surrounding area. These caves are situated within the seismically active region between the Main Central Thrust (MCT) and the Main Boundary Thrust (MBT), struck by medium to large earthquakes in the past. The study contributes to understanding seismic activities linked to hinterland structures, such as the MCT, MBT, or other minor thrusts, in contrast to great décollement earthquakes impacting the Himalayan Frontal Thrust (HFT).

During our exploration of these caves, numerous displaced and broken speleothems were observed, accompanied by the subsequent growth of second-generation stalagmites on these formations. Additionally, the caves displayed fallen ceilings and ~60 cm to 2m thick speleothem debris, containing broken soda straws, small stalactites, and chunks of fallen ceilings. Growth perturbations in stalagmites encompass sudden tilting, rotation, termination, and faulting within laminas, providing a detailed record of past seismic activities. Detailed petrographic analysis of twenty thin sections from stalagmites unveiled distorted microstructures and fragments of broken soda straws. The broken calcite crystals and aragonite needles are evident in a few slides under Scanning electron microscope (SEM) analysis. Advanced analytical analysis, including Raman spectroscopy and Laser-Induced Breakdown Spectroscopy (LIBS) of five distorted speleothems, provided insights into mineralogical and trace element composition changes. In some samples, the inclusion of silica and aluminum-rich detrital sediment was identified within the growth anomalies. Notably, stable isotopic records did not indicate signatures of floods or droughts. Utilizing U-Th age data from six specimens, we pinpoint intervals for these growth anomalies, dating them at 4273±410 years BP (2673–1853 BCE), 2782±79 years BP (851–693 BCE), 2498±117 years BP (605–371 BCE), 1503±245 years BP (262–752 CE), 1346±101 years BP (563–765 CE), and 687±147 years BP (1176–1470 CE). These chronologies potentially align with major seismic events, with the most recent event (1176–1470 AD) corresponding chronologically to a documented great medieval earthquake (1050–1250 and 1259–1433 AD) observed in trench

excavations along the Himalayan Frontal Thrust." This alignment underscores the potential link between these growth anomalies and significant seismic activities in the region during different historical periods.

Small mammal fossils from cave sediments and their use for palaeoenvironmental reconstructions. Potential and limitation

Lutz Christian MAUL[1]*, Senckenberg Research Station of Quaternary Palaeontology (lmaul@senckenberg.de)
Jaishri Sanwal[2], Geosciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore 560064, India
Chris Baumann[3], Department of Geoscience, University of Tübingen, Hölderlinstrasse 12, 72074 Tübingen, Germany

Abstract

Palaeontological data provide important contributions to palaeoenvironmental reconstructions. At terrestrial sites, this is particularly true for small mammals (insectivores, bats, rodents and lagomorphs). They are very informative because of their usually rich fossil record, their wide geographical distribution, their biostratigraphic importance and their often very close adaptation to certain habitats. For such reconstructions, the nearest living relatives (NRLs) of the fossil taxa are usually used, either in the form of ecological groups for open land, forest, aquatic habitats, etc., or attempts are made to quantify them, usually via recent ranges and the ecological or climatic parameters that can be derived from them. If the site consists of only one fossil layer, an ecological snapshot can be derived; if it consists of several layers, an ecological sequence can be derived. Among the various types of fossil sites, caves are among the most important archives.

Results and problems of palaeoecological reconstruction are discussed for three Quaternary cave faunas from Central Europe. (1) The cave profile from Koněprusy C718 (Czech Republic) shows a sequence of the relative abundance of different fossil vole taxa from the early Middle Pleistocene (early Cromer complex). Although none of the fossil species can be fully shown to be ecologically comparable to their recent relatives, the sequence shows a clear picture of the succession from a forested, warmer environment to an open, colder one: some taxa with presumed similarities in ecological adaptation (dry, cold vs. wetter, temperate affinities) change in parallel - some in opposite directions. Others, however, are changing without any discernible pattern. (2) Small mammals in the sequence of Hunas Cave (Germany) reflect different phases of the late Middle to Late Pleistocene. A cold phase in the upper part, characterised by Lemmus lemmus, Microtus oeconomus and M. gregalis, a continental phase in the middle part, defined by Ochotona, Cricetus, Phodopus, Spermophilus and Marmota, and a warm phase in the lower part of the profile, reflected by the occurrence of Muscardinus and Microtus subterraneus. (3) The Pisede burrow complex (Germany), which was created by badgers and inhabited for several centuries, contained extensive micro faunal material dating from the terminal Pleistocene to the early Holocene. During use, the structure was extended, and older areas were reworked several times. This generally resulted in a horizontal stratigraphy with massive faunal assemblages.

The three examples show that palaeoecological reconstructions based on small mammals are mostly conclusive, although uncertainties remain. Despite the risk of misidentification and the inherent differences between fossil and modern species, leading to uncertain ecological

conditions, ongoing research efforts are aimed at refining this understanding. It's worth noting that older faunas present greater challenges in this regard. In addition, the mixing of faunas, possibly due to bioturbation, can complicate the accurate stratigraphic placement of different units. Taphonomic filters, influenced by cave dwellers or the prey spectrum of accumulating raptors, especially owls, also contribute to this complexity. To increase the robustness of the results, consistent cross-checking with palaeoenvironmental reconstructions derived from other methods, such as palaeobotanical or geochemical data, is encouraged.

Past-WDs modeling using CMIP6 Paleoclimate Modeling Intercomparison Project (PMIP4) Experiments and Speleothems Over Hindukush Himalaya.

Pramod KUMAR[1]*, Banaras Hindu University, Varanasi, India (promnagar1@gmail.com)
Om Kumar[2], Miranda House, University of Delhi, New Delhi, India, 110007

Abstract

Western Disturbances (WDs) have a very crucial role in snowfall/rainfall over the Western Himalayas. Subsequently, WDs are a major contributor to water resources over Hindukush Himalaya (HKH) through rainfall, snowfall, and other forms of precipitation. The Himalayas are one of the freshwater reservoirs that contain glaciers, rivers, springs, and lakes, which nourish various communities in HKH. However, utilizing CMIP6 model PMIP4 paleo-experiments and speleothems (proxies), it can be better understood the past contribution made by WD precipitation. The subtropical westerly jet is captured in synoptic-scale systems, termed WDs. The western Himalayas receive greater precipitation due to extensive orographic interaction. However, the winter monsoon (WM) refers to the precipitation caused by WDs and other factors. Paleoclimatology of HKH using δ13C and δ18O can give the actual climatic scenario and weather pattern. The study evaluates the fingerprints of oxygen isotopes in model simulations and speleothem records. The model generates a higher level of δ18O variations than what is observed in speleothem archives. Although interpreting speleothem data might be difficult, it has the potential to aid in climate reconstruction. It should be considered to use a multi-model technique when evaluating modelled and proxy data. More detailed modelling requires an understanding of the underlying mechanics of karst and caves in HKH.

Evidence from southern India suggests that the Little Ice Age was not uniformly cold and dry across the globe.

ISHFAQ AHMAD MIR[1]*, Geological Survey of India (geoishfaq@gmail.com)
Jooly Jaiswal[2], Geological Survey of India
Anindya Bhattacharya[3], Geological Survey of India

Abstract

A radiocarbon-dated sediment core from Honnamankere Lake in southern India's Western Ghats is being examined to learn more about the area's paleoclimate between CE 1219 and 1942. The current study aims to better comprehend evolving continental weathering regimes in peninsular India over the last 753 years, including the medieval warming period (MWP: CE 1219-1374), little ice age (LIA: CE 1374-1671), and modern global warming (MGW: CE 1671-1942). The chemical weathering and erosion proxies in the catchment region have low values during MWP and MGW, indicating a drop in rainfall, but high values during LIA, indicating an increase in rainfall. The downward trend in the sediment core shows that a warm and humid environment governs both physical erosion and chemical weathering. Higher latitudes had less physical erosion and chemical weathering during the LIA. The LIA in the research area was warm and moister, rather than cold and dry. The LIA, a global climatic phenomena characterized by significant diversity in rainfall patterns, calls into question the widely held idea of a continuously cold and dry climate with reduced monsoon rainfall throughout the LIA. This study underlines the importance of looking at alternative high resolution paleoclimate archives in the region, including as speleothems and tree rings, in order to better explain LIA oscillations between lower and higher latitudes. The high resolution multi-proxy and multi-archive paleoclimate records could help to improve climate models for future forecasts. Accurate climate models will aid in strong scientific policy planning, both of which will be extremely beneficial to the world's most populous country, India, where agriculture makes for a sizable portion of its GDP. Human-induced climate change demands extensive modelling studies for accurate projections, and our data, together with future studies in the region on speleothems, tree rings, and corals, can make a significant contribution.

[Keynote] New Palaeolithic Explorations in Eastern Asia

Shixia YANG[1]*, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences (yangshixia@ivpp.ac.cn)

Abstract

The evolutionary history of humans and our closely related early ancestors is one of the most important scientific endeavors. Current knowledge about human evolution is mainly based on the fossil and archaeological record in Africa and Europe. Yet, Eastern Asia is known for its long sequences of Quaternary terrestrial deposits, which have supplied detailed information about changes in environments and the history of hominin occupations. However, few systematic and coordinated research efforts have been conducted in Eastern Asia to bridge its climatic history with its rich paleoanthropological records.

This talk will introduce a series of new scientific studies focused on the evolutionary history of hominins in Eastern Asia. These studies, covering the entire length of the Paleolithic, are altering our views about the evolution of hominins in Eastern Asia. In contrast to traditional arguments for a homogeneous and continuous record of the Paleolithic in Eastern Asia, the new findings demonstrate the potential complexity of early human adaptions in Eastern Asia, and the close relationship between early human behavior and climatic events. With respect to behavioral adaptions of modern humans in Eastern Asia, recent studies suggest that we should pay close attention to a mosaic of behavioral adaptations and innovations occurring during the worldwide dispersal of our species, rather than simple diffusion and replacement.

Early Holocene human in the Tengger Desert, northern China

xuefeng SUN[1]*, Nanjing University (xuefeng@nju.edu.cn)

Abstract

By the onset of the Holocene, the ability to exploit new territory of hunting and gathering people have been significantly improved in the worldwide. But one area that remained largely unidentified was the desert regions in northwest China. Since 1989 a small number of surface prehistoric remains were discovered in the Tengger Desert Region (TDR) northern China. However, until now, we have never known when humans occupied the TDR, when they left, and where they went in the end. Between 2020 and 2023, we found 60 stone artifact sites (TGL4-TGL63) including a human bone site (TGL43) in the Tengger Desert Region (TDR), northern China. The Tengger Desert lithic assemblage is core-flake-retouched flake tools industry and microlithic industry. Three AMS 14C samples dating showed TGL43 human bones is 7560-7267 yr BP. Then 79 OSL samples dating in 9 burial sites and 23 surfaces sites suggested the initial occupation before 9 ka, activities between 9 ka and 6 ka by, and extinction or migration after 6 ka by the hunting and gathering people around several hundred square kilometers in the TDR northern China. An ancient genome from the TGL43 human showed a lonely and isolated human population, and Tengger human seem to have disappeared. However, it shed light on the genetic origin of Yangshao farmer's related ancestry.

Chenglong Deng[8], State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

The timing and mechanism of modern Human's dispersal and occupation into North China, especially cultural interactions between exogenous Paleolithic populations and those indigenous to East Asia during the Late Pleistocene are of great interest.

Homo sapiens dispersed eastward into Siberia and Northeast Asia after ~45 ka. When anatomically modern humans crossed the Mongolian steppe/desert and dispersed further across East Asia, encounters between allochthonous modern humans and indigenous hunter-gatherers inevitably occurred, possibly leading to population replacement and geographical shifts. How they colonized and interacted with autochthonous Paleolithic populations in East Asia remains ambiguous.

In this study, two Paleolithic sites (YZXS and TZL) located in the southern piedmont highland of the Yanshan Mountains, with artifacts typified by simple core and flake technology associated with foraging populations, have been dated to ~39-29 ka and ~53-47 ka respectively, using Optically Stimulated Luminescence (OSL). Our results suggest that North China south to the Yanshan Mountains was occupied mainly by autochthonous East Asian Paleolithic populations using a core-flake technology, although during this period Initial Upper Paleolithic (IUP) modern human populations have been present in Western Europe and dispersed into Asia. By synthesizing and integrating the ages of Northeast Asian Paleolithic sequences during the last glacial period (ca. 70-10 ka), we analyzed spatio-temporal variations in Late Pleistocene human populations during relatively cold stadial events (MISs 4 & 2) and warmer interstadials (e.g., MIS 3), revealing an "ebb and flow" pattern for migrations of the Western IUP "blade" populations and indigenous "core-flake" populations in East Asia corresponding to the advance and retreatment of the East Asian monsoon belt around the Greater Khingan and Yanshan mountain ranges. During relatively cold MIS 4, only a few small indigenous human populations remained in the Qinling

Mountains and along the North Chinese coastline. During subsequent MIS 3, a warm climate both facilitated expansion of the autochthonous “core-flake” population size and the dispersal of populations whose lithic technology focused on the production of blades. However, the subsequent extremely cold climate phase engendered a major population shift during the Last Glacial Maximum (LGM; ca. 26.5-19 ka), which drove the recession of both these Paleolithic populations, but afterward facilitated the emergence and rapid dispersal of microblade populations in Northeast Asia, including North China. These populations associated with microblade technologies achieved their maximum extent during the warm Bølling-Allerød interstadial event (ca. 14.7-12.9 ka) and then gradually decreased, perhaps due to the development of agriculture after ~13 ka.

Discovery and research at Xuetangliangzi in the Yunxian hominin site, central China

Chengqiu LU[1]*, Hubei Provincial Institute of Cultural Relics and Archaeology (5457167@qq.com)

Abstract

The Xuetangliangzi site is located in Yunyang District, Shiyan City, Hubei Province, in the central part of China. It is renowned for the discovery of Yunxian hominin crania and is also known as the Yunxian Man Site. The site is situated on the left bank of the upper reaches of the Han River, west of the Quyuan River estuary. It is an important Paleolithic site that contains a combination of hominin fossils, mammal fossils, and stone artifacts. The site covers an area of over 1.9 million square meters and has an average thickness of Quaternary deposits reaching 8 meters, preserving stratigraphic deposits from different periods spanning over one million years. In the archaeological survey of 1989, the Yunxian Man No. 1 cranium was discovered. During the first excavation in 1990, the Yunxian Man No. 2 cranium was unearthed. In the seventh excavation in 2022, the even better-preserved Yunxian Man No. 3 cranium, along with a large number of mammal fossils and stone artifacts, was discovered. Compared to the severely deformed yet relatively complete Yunxian Man No. 1 and 2 crania, the newly found Yunxian No. 3 cranium shows no apparent deformation. It is the most well-preserved hominin cranium of the same age ever discovered in the Eurasian mainland. All three crania were found in the same stratigraphic layer, and dating methods, such as electron spin resonance, uranium series, and paleomagnetism, indicate an approximate age of one million years.

Abstract

The Proterozoic witnessed the emergence and rise of early eukaryotes, which have played an important part in improving the habitability of the early Earth. Proterozoic carbonaceous compression macrofossils can provide important clues to our understanding of the ecological expansion of early eukaryotes as well as their role in the evolution of habitability of the early Earth. Among them, the discoidal to elliptical form chuarid, represented by *Chuaria*, and the elongate to tomaculate form tawuid, represented by *Tawuia*, are among the most common fossil forms in Proterozoic successions, which often co-occur in the same bedding layer and both have extremely long temporal and broad geographical distributions. However, the phylogenetic interpretations of chuarids and tawuids and the relationship between them have been debated for decades, due to their simple morphologies lacking phylogenetically diagnostic features.

To resolve the taxonomic chaos and explore the potential biological relationship of chuarids and tawuids, we used an integrated application of reflected and transmitted light microscopy, scanning electron microscopy, biometric analysis, and Raman spectroscopy to characterize well-preserved carbonaceous compression macrofossils of *Chuaria* and *Tawuia* from the Tonian Liulaobei

Formation (~1.0 Ga) in Huainan region, North China. The fossils are abundantly preserved in a ca. 10–20 mm thick homogeneous mudstone layer and can be considered to be closer to an ecological community than fossils from multiple different layers or localities. The comprehensive analysis shows that even *Chuaria* vesicles from the same layer may have a polyphyletic origin and several groups of *Chuaria* vesicles have been identified. Among them, a group of small *Chuaria* vesicles with minimum diameter <1.2 mm can be related to the sphaeromorphic acritarch *Leiosphaeridia*. In contrast, a group of large *Chuaria* vesicles with minimum diameter ≥1.2 mm are more comparable to the type material of *Chuaria circularis* from the Chuar Group and more closely related, either phylogenetically or ontogenetically, to *Tawuia* vesicles.

The seemingly simple chuarids and tawuids from other Proterozoic successions may also have multiple sources, particularly for *Chuaria*, and their morphological simplicity may be resulted from the convergent evolution of different but morphologically similar organisms. Therefore, the species diversity and maybe also the geobiological role of Proterozoic *Chuaria-Tawuia* assemblages and sole *Chuaria* assemblages might have been underestimated. This study takes a step on the path to solving the mystery of the most common and widely distributed Proterozoic macrofossil assemblage, and urges thorough and systematic evaluations to be taken on the possibility of polyphyletic origins for *Chuaria-Tawuia* assemblages or sole *Chuaria* assemblages in other Proterozoic localities.

Abstract

The Tonian Period represents a critical transition from a prokaryote-dominated biosphere to a eukaryote-dominated biosphere in the early Earth. However, our understanding of the Tonian benthic eukaryotes and their role in improving the habitability of the substrate of benthic ecosystem is quite limited. Discoidal fossils (e.g., *Chuaria* and abundant unnamed discs) and tubular fossils (e.g., *Tawuia* and the worm-like annulated taxa *Protoarenicola*, *Pararenicola*, and *Sinosabellidites*), dominate most Tonian macrofossil assemblages. Previous work on Proterozoic materials indicated that some discoidal fossils could be detached holdfasts of co-occurring erect benthic organisms, but little attempt has been made to quantify the potential relationship between the discoidal fossils and the discoidal holdfasts of tubular fossils from Tonian successions. Recently, we have confirmed biometric and chemospatial links between discoidal fossils with a central opening and worm-like annulated tubular fossils from the Tonian Jiuliqiao Formation (~950–720 Ma) in Huainan region, northern Anhui province, North China, which supports the notion that the discoidal fossils with central opening represent detached holdfasts of tubular fossils and that tubular fossils with or without a holdfast share a potential biological or ontogenic relationship. Meanwhile, the clustered discoidal fossils with central openings were interpreted as holdfast coalescence (physical contact and fusion of two or more adjacent holdfasts) for Pre-Cryogenian benthic algae, which is supported by the clustered holdfasts of Protoarenicola specimens. Holdfast coalescence may have become a common strategy for Tonian algae in benthic ecosystems as an ecological response to relatively strong hydrodynamic forces. Detached holdfasts and holdfast coalescence may be more common than we

have thought in the Pre-Cryogenian, and the paleoecological and geobiological role of benthic algae and their holdfasts during this period is probably underestimated. Our study also highlights the adaptation of holdfast morphology to Precambrian mat-ground substrate, and provides evidence for the co-evolution of substrate and benthic organismic morphology during this period.

Xunlai Yuan[5], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences
Shuhai Xiao[6], Department of Geosciences and Global Change Center, Virginia Tech

Abstract

Lichens are symbiotic associations of fungi (mycobionts) and cyanobacteria/algae (photobionts). They are of pivotal importance in continental weathering and landform evolution. However, the scarcity of lichen fossils, particularly in the Precambrian, hampers our ability to reconstruct the tempo and mode of lichen-like symbiosis and to assess the impact of lichen-like organisms on continental weathering. In this study, we systematically re-describe previously reported lichen-like fossils from the early Ediacaran Weng'an biota (~600 Ma) in South China. These fossils are characterized by a non-stratified thallus consisting of filamentous mycobionts and coccoidal photobionts, the latter ensheathed by a translucent envelope. The mycobionts are composed of uniseriate, sometimes dichotomously branching, hyphae and terminal, occasionally intercalary, vesicles interpreted as spores. They share some similarity with Glomeromycetes, most of whose extant representatives (i.e., arbuscular mycorrhizal fungi) develop a symbiotic relationship with vascular plants. The photobionts are preserved with different stages of cell division, the most common of which is the tetrad stage, and can be compared with lichen photobionts from the Early Devonian Rhynie chert. Confocal Laser Scanning Microscopy (CLSM) reveals some possible interactions between the mycobionts and photobionts, including encirclement where the photobionts are partially surrounded by curved hyphae. These interactions imply that the Weng'an lichen-like fossils are protothalli with some symbiotic features yet rather primitive relative to extant lichens. For comparison, we also carried out detailed observations on the possible symbiotic association of filamentous and spheroidal fossils from the basal Ediacaran cap dolostone of the Doushantuo Formation (~635 Ma) in the Weng'an area, South China. Symbiotic association in the basal Ediacaran fossils, probably in a prethallus stage, is still more primitive. Overall, our study of early Ediacaran symbiotic fossils indicates that the origin of lichenization and therefore its impact on the Earth-life system may have a deeper root than previously thought.

Stromatolites improved the habitability of Precambrian seafloor: Evidence from the molar-tooth structure in the Tonian Jiudingshan Fm., North China

Xubin WANG[1]*, Peking University (xubinwang@pku.edu.cn)
Lin Dong[2], Peking University

Abstract

The oxygenation of Earth's surface environment, primarily the atmosphere and the ocean, is the key to the habitability for metazoans. The Great Oxygenation Event (GOE) and Neoproterozoic Oxygenation Event (NOE) represent permanent rises of atmospheric oxygen levels, representing crucial environmental evolutions during the Precambrian. However, the oxygen level hardly changed between GOE and NOE, a period often referred to as the 'Boring Billion' (~1.8 Ga to ~0.8 Ga). At the end of Boring Billion, The Tonian Period marks a critical node in biological evolution, evidenced by the origin of metazoans from molecular clock dating, phosphatic biomineralization in microfossils, and active predation documented from organic-walled microorganisms. Despite likely sufficient nutrient levels in seawater, including both phosphorus and nitrogen, widespread shallow-water anoxia prevailed in the Tonian oceans. These findings lead to a knowledge gap between the environmental and biological evolutions: how early metazoans can originate, survive, and possibly be diverse in the face of low atmospheric-oceanic oxygen levels. Here, we investigate the petrological features of the Jiudingshan Formation in the Huaibei Group, North China. Abundant and diverse molar-tooth structures (MTs) are found in the Jiudingshan carbonate depositions, which exhibit large divergence in morphology, size, and mineralogy. The sparry matrix could recrystallize around the MTs, suggesting that the matrix is more unstable. MTs only exist in the basal succession, with no evidence of their occurrence in the overlying stromatolite layers. Besides, sedimentary pyrite is observed only at the top of the MTs-bearing succession, suggesting a transition in the marine sulfate pool. The presence of stromatolites overlying MTs probably indicates an environmental shift associated with an increase in sulfate concentration. To sum up, the Jiudingshan Fm. may represent an oxygenation event in the Tonian oceans, likely facilitated by stromatolites, and holds the potential to restrict evolutions within the marine sulfate pool.

Large magnitude sulfur isotope mass independent fractionation indicating subaerial volcanism in 3.8 Ga

Ruimin WANG[1]*, Peking University (ruiminwang@pku.edu.cn)
Bing Shen[2], Peking University
Dominic Papineau[3], University College London
Wei Yang[4], Institute of Geology and Geophysics, Chinese Academy of Sciences
Mang Lin[5], Guangzhou Institute of Geochemistry, Chinese Academy of Sciences

Abstract

The continental crust, mostly above sea level, has been playing key roles in maintaining Earth's long-term habitability. Continental weathering consumes CO2 in the atmosphere, affecting the global temperatures, and supplies nutrients for the surface ocean primary productivity and redox-sensitive components. Thus, understanding when and how continental crust formed is pivotal in unraveling the evolutionary history of habitability. However, evidence for the earliest continental crust formation is limited from both geological and geochemical perspectives. Here, we apply mass-independent fractionation of sulfur isotope (S-MIF) signal of sulfides (e.g., sedimentary pyrites and pyrrhotites) to constrain subaerial volcanic eruptions. We report sulfur isotopes of pyrites and pyrrhotites from 3.8 Ga banded iron formation (BIF) in the Nuvvuagittuq Supracrustal Belt. Nano-SIMS analyses of sulfide crystals reveal limited variations in δ34S but large magnitude S-MIF signals (Δ33S) ranging from -2 to +11‰. The nearly invariant δ34S may indicate absence of dissimilatory sulfate reduction (DSR) or quantitative reduction of sulfate, while the large magnitude S-MIF may imply a large flux of S8 from the atmosphere and mixing with negligible terrestrial H2S. This observation could be interpreted as indicative of extensive subaerial volcanism characterized by high SO2/H2S ratios, suggesting the presence of landmass above sea level. The presence of topographically elevated land mass at 3.8 Ga might have profound impacts on the habitability of the early Earth.

[Keynote] The expansion of marine eukaryotes in the early Neoproterozoic Era

Shuhai Xiao[1]*, Department of Geosciences, Virginia Tech, Blacksburg, VA 24061, USA (xiao@vt.edu)
Junyao Kang[2], Department of Geosciences, Virginia Tech, Blacksburg, VA 24061, USA
Qing Tang[3], School of Earth Sciences and Engineering, Nanjing University, Nanjing 210023, China

Abstract

Molecular clocks and paleontological data indicate that the Eukarya diverged from the Archaea no later than the Paleoproterozoic Era (2,500–1,600 Ma). However, the taxonomic diversity, morphological disparity, and ecological importance of marine eukaryotes remained relatively low until the Tonian Period (1,000–720 Ma) of the Neoproterozoic Era. The drivers of taxonomic diversification, morphological expansion, and ecological rise of Tonian marine eukaryotes are poorly understood. In this presentation, we review currently available paleontological and geochemical data to assess various hypotheses about the drivers, including a Tonian intensification of ecological interactions (e.g., predation, symbiosis) and a Tonian increase in the availability of marine macronutrients (particularly phosphate and nitrate) and bio-essential metals. Together, these factors may have enabled the taxonomic, morphological, and ecological rise of photosynthetic eukaryotes in the Tonian Period, which, in turn, opened ecological opportunities for the diversification of eukaryotes overall, resulting in the transition from a prokaryote-dominated to a eukaryote-dominated marine ecosystem. Ultimately, this transition may have led to fundamental changes in export bioproduction, global carbon cycles, nutrient recycling, and marine redox structures. These changes may have had profound impact on the Earth system and in the long run may have contributed to snowball Earth glaciations in the following Cryogenian Period (720–635 Ma).

Unique Archean phosphorous cycle linked to submarine hydrothermal and biological activities

Takeshi KAKEGAWA[1]*, Tohoku University (kakegawa@tohoku.ac.jp)

Abstract

Archean phosphorous cycles have been debated in last decades. On the other hand, the source and speciation of phosphorous in the Archean oceans were still uncertain. Geochemical and mineralogical studies were performed on Archean submarine volcanic rocks and banded iron formations from Pilbara (3.4 Ga), Barberton (3.2 Ga) and Abitibi and Wawa (2.7 Ga). The examined basalts and rhyolites were suffered from submarine hydrothermal alteration and seafloor CO2 metasomatism. They contained various secondary apatite and monazite. This observation and thermodynamic calculations indicate that phosphate was a dominant specie in the migrating fluids, rather than reduced phosphorous species. Altered volcanic rocks are in general depleted in phosphorous concentrations. These findings suggest that Archean oceanic crusts behaved as the source of phosphorous in the global phosphorous cycle. This suggestion is contradicting to the modern phosphorous cycle.

A part of examined BIFs (3.2 Ga and 2.7 Ga) were found to be rich in phosphate (up to 0.8 wt%). In addition, apatite grains are spatially associated with organic matter in the examined samples. This further indicates the phosphate accumulation in BIFs through sedimentary organic matter, not by Fe-(hydro) oxide adsorption. Those results indicate that phosphate concentrations were rather high in the Archean oceans and microbial sink of phosphate were significant in Archean oceans.

Abstract

Sulfur is a redox active element that may have helped mediate the electron flow which kickstarted life, and is a bioessential element for all life on Earth. Despite current uncertainties in global sulfur fluxes, modeling sulfur's abiotic cycling through Earth's deep history is important for understanding the impact of a planet-wide biosphere on sulfur's geochemical cycling and availability and vice versa. We present here an open-source, dynamical box model for estimating global sulfur fluxes and concentrations among surface and deep Earth reservoirs over Earth history, allowing tracking and estimation of the sulfur distribution in planetary reservoirs over deep time in the absence of life. While the main model presented here does not take into account the abrupt evolution of redox-shunting biosynthetic pathways such as oxygenic photosynthesis, we also modeled the abiotic sulfur cycle before and after the Great Oxidation Event (GOE) on Earth-like planets. Our results suggest a considerably distinct chemical makeup of sulfur content in marine sediments in the absence of life on an Earth-like planet, leading to a marine sediment sulfate content four orders of magnitude larger than on present-day Earth, attributable to the lack of microbial sulfate reduction. This model could be useful for understanding sulfur cycling on potentially habitable exoplanets.

Abstract

Several special geological phenomena during Mesoarchean have been discovered: (1) significant increase in crustal thickness at ~3.0 Ga; (2) high-K granites widely developed in several cratons at ~3.1-3.0 Ga; (3) all the cratons in the same region of Pangea became stable at – 3.0 Ga. All these evidences suggest that a great geological event happened during Mesoarchean. To plumb what happened in Mesoarchean during earth history, metamorphic rocks metamorphosed at ~3.0 Ga and magmatic rocks formed between ~3.2-3.0 Ga in the western Dharwar craton, southern India were investigated. Metamorphic chronological data of pre-Neoarchean are important but relatively sparse. Mesoarchean (ca. 3.0 Ga) metamorphic rocks, including metamafic and metapelitic rocks, outcrop in the Banavara area, western Dharwar Craton, southern India. They provide a critical example to understand the tectonic evolution of the Dharwar Craton. The main mineral assemblage of metamafic rocks is composed of garnet, amphibole, plagioclase, quartz and partial retrogressive epidote, while main mineral assemblage of metapelitic rocks consists of coarse-grained garnet, quartz, muscovite, biotite, sillimanite and retrogressive chlorite. Metamorphic zircon U-Pb dating of two meta-mafic rock samples yield metamorphic ages of 2967±18 Ma and 2976±14 Ma, respectively. Zircons of two meta-pelitic rock samples yield metamorphic ages of 2959±8 Ma and 2960±9 Ma, respectively, and inherited detrital zircon age of 3202±33 Ma. These metamafic and metapelitic rocks were previously considered as Paleoarchean-Mesoarchean (ca. 3.4-3.1 Ga) rock unit of the Sargur greenstone belt, and underwent amphibolite-granulite facies metamorphism in Neoarchean. This study further confirms that the metamorphism of the Sargur greenstone belt occur in Mesoarchean (ca. 3.0-2.95 Ga). The Mesoarchean magmatic rocks including TTGs and basic intrusive rocks mainly formed at ~3.38-3.21 Ga, and the high-K granites mainly formed at ~3.15-2.96 Ga in the western Dharwar craton. The TTGs and basic intrusive rocks mostly have depleted zircon Hf and whole-rock Nd compositions, while the high-K granites mostly have enriched zircon Hf and whole-rock Nd compositions. These data indicate crustal growth event at ~3.4-3.2 Ga, and crustal reworking event at ~3.1-3.0 Ga in the western Dharwar craton. Combined with the occurrence of the ca. 3.2-3.1 Ga crustal rocks expose in the

eastern Dharwar Craton, it could be speculated that the western Dharwar Craton and the eastern Dharwar Craton might have been a united block before ca. 3.0 Ga. The similar geological events related to Mesoarchean magmatic and/or metamorphic were also discovered in the Kaapvaal craton, Singhbhum craton, Pilbara craton and Gawler craton. Accordingly, we infer that a global-scale crust-mantle interaction may have possibly occurred in Mesoarchean at ~3.2-3.0 Ga.

Abstract

The Datangpo Fm and correlative Xiangmeng Fm record continuous siliciclastic deposition in the Nanhua Basin, South China, during the Cryogenian non-glacial interval (Zhang et al., 2015; Bao et al., 2018; Peng et al., 2019). The formations are sandwiched between two major glacial diamictites, the older Tiesi'ao Fm (Gucheng Fm in western Hunan Province) and the younger Nantuo Fm (Zhang et al., 2008; Peng et al., 2019). Previous δ98Mo studies of organic-rich black shales from the Datangpo Fm (e.g., Chen et al., 2015; Cheng et al., 2018) relied upon extrapolating seawater δ98Mo for the entire Cryogenian non-glacial interval from black shales of the lower Datangpo Fm only, which constitute a small fraction of the total thickness of Cryogenian non-glacial deposits.

Here, we investigate local and global palaeoredox dynamics using integrated Fe-speciation and redox-sensitive trace element (RSE) systematics, in addition to δ98Mo, from drill core Xiangtan (core ZK3603), for which the detailed lithostratigraphy has been described by Peng et al. (2019). We critically assess existing δ98Mo datasets from globally distributed Cryogenian non-glacial successions and use our best estimate of seawater δ98Mo and Mo concentration ([Mo]) to calibrate a single reservoir model in an attempt to better constrain the link between Sturtian deglaciation and global ocean palaeoredox.

The δ98Mo compositions of black shales from the Xiangtan section range from −1.07 to +1.28‰ (mean = +0.66‰). In the Xiangtan section, FeHR/FeT >0.38 demonstrates significant enrichments in highly reactive iron, coupled with high Fepy/FeHR ratios (0.49 to 0.88), including 15 samples >0.6 that have the potential to capture seawater δ98Mo composition. These data suggest that black shales of the Xiangtan section likely accumulated under dominantly sulfidic/euxinic conditions. Samples with FeHR/FeT >0.38 and Fepy/FeHR >0.70 can be subdivided into a lower interval (570 – 510.5 m), where values of δ98Mo remain relatively invariant in the range +0.75 to +0.81‰, and an upper interval (508.5 – 482 m), where δ98Mo has greater variability, in the range +0.27 to +1.28‰.

Integrating published data from the Arena Formation of Greenland with new and published data from the Datangpo and Xiangmeng formations may therefore yield a continuous record of δ98Mo throughout the non-glacial interval. Within this framework, seawater δ98Mo may have approached +1.47‰ in the immediate aftermath of the Sturtian deglaciation, decreased to +0.81‰ during MnOx deposition, and recovered to +1.28‰ in the latter half of the Cryogenian non-glacial.

Abstract

Eoarchean rocks are scarce worldwide, limiting our understanding of the Earth's early history. We carried out integrated field and petrographic work, whole rock geochemistry and zircon U-Pb-Hf-O analyses on Eoarchean granitoid rocks, including 3838–3754 trondhjemitic gneisses, 3786–3773 Ma granodioritic gneisses, 3775 Ma quartz monzonite gneiss and 3786–3640 Ma potassic granite gneisses, newly-discovered in the Labashan area, eastern Hebei, North China Craton. The granitoids are identified in a tract 1 km long. They are in tectonic contact with 3.4–3.1 Ga supracrustal rocks, with both occurring as enclaves in 2.5 Ga potassic granite. The trondhjemitic gneisses show low (La/Yb)n values (23.4–56.8) and insignificant Eu anomalies (Eu/Eu* = 0.86–1.24). Compared with the trondhjemitic gneisses, the granodioritic gneisses and quartz monzonite gneiss have lower (La/Yb)n ratios (9.2–11.3) and lower Eu/Eu* values (0.62–0.79). The potassic granites have (La/Yb)n ratios of 20.65–55.23 and insignificant and Eu/Eu* values of 0.75–1.84). Zircon saturation temperatures of the granitoids range from 667 to 878 ℃. They have whole-rock εNd(t) of -4.6 to 1.0 and tCHUR(Nd) of 4.3 to 3.6 Ga, and zircon εHf(t) values of -6.9 to 0.4 and tCHUR(Hf) ages of 4.1 to 3.5 Ga (mainly 4.1 to 3.8 Ga) and δ18O of 4.6 to 7.5 ‰. It is speculated that the granitoids are derived from a mixture of mafic and earliest (>3.8 Ga) tonalitic sources, with the granites representing ‘pure’ melts of older continental crust. The rock types and compositional features show diversity at 3.8 Ga, indicating that by then the local continental crust had reached a high degree of evolution. Two possible models, magma underplating and plate subduction, are explored for the tectonic regime forming the Eoarchean granitoids.

Zongjun YIN[3], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Abstract

Biological organic molecules preserved within Precambrian banded iron formations (BIFs) can provide valuable information about the origin and evolution of life. Metamorphism leads to the alteration of organic molecules associated with traces of early life in BIFs, where certain minerals can serve as protective armors, shielding these organics from decomposition. Despite this, identifying and preserving early life traces in BIFs faces significant challenges. The degree to which remnants of biological organics are preserved, along with the protective capabilities of various minerals during metamorphism, still need to be fully understood. Here, we present petrographic observations and Time-of-Flight Secondary Ion Mass Spectrometry (TOF-SIMS) analyses on the organic matter (OM) in a ~2.5 Ga BIF from North China, which has undergone lower amphibolite-facies prograde metamorphism. The OM is in paragenetic equilibrium with prograde mineral phases and is often associated with apatite that occurs in Fe-rich bands parallel to layering. Raman spectroscopy reveals that the maximum metamorphic crystallization temperature is consistent with the metamorphic peak conditions of the host BIF. The BIF possesses average bulk 13Corganic values of −20.0‰ and δ13Ccarbonate values of −12.9‰, indicating biomass remineralization during prograde metamorphism. TOF-SIMS analyses show the presence of biological molecular remnants, including H-bearing aromatic compounds and N-bearing aliphatic compounds, within the OM. This further supports the hypothesis that the OM likely originates from biomass deposited contemporaneously with the BIF. Notably, the spatial distribution of these molecular remnants exhibits a strong correlation with mineralogy, suggesting that different minerals may offer varying levels of protection to organic molecules during the process of metamorphism. Our findings highlight the importance of understanding how minerals influence the preservation of molecular information related to early life. This understanding is essential for deciphering the complex abiotic interactions between geological processes and the biosignatures on Earth and other rocky planets.

Redox-stratified seawater during the GOE: Evidences from rare earth elemental and C-O isotopic compositions of Paleoproterozoic BIFs and carbonate rocks from the Taihua Group, North China Craton

Cai Yun LAN[1]*, Northwest University (lancaiyun@nwu.edu.cn)
Xiao Ping Long[2], Northwest University

Abstract

The Paleoproterozoic Great Oxidation Event (GOE) is known for the dramatic change in atmospheric composition that led to oxygen becoming a persistent component of global surface processes. Drastic environmental changes greatly affected ocean and atmosphere chemistry. However, the distribution of dissolved oxygen in the ocean during the GOE is still unclear as rare contemporary sediment-records have been found. In order to identify the redox state of both shallow and deep water, and reveal the ocean redox structure during this time, we present new major and trace elemental and C-O isotopic data of bulk samples of the banded iron formation (BIF), dolomitic marble, and graphite-bearing marble of the early Paleoproterozoic upper Taihua Group in the Lushan area, southern margin of the North China Craton (NCC). The BIF samples exhibit typical major and trace element characteristics akin to very pure marine chemical sediments, such as the shale-normalized positive La, Ga, and Y anomalies, indicative of a marine depositional setting. In these BIF samples, both negative Ce anomalies and the lack of Ce anomalies reflect the presence of both oxic and suboxic/anoxic water in the ocean. Samples of the dolomitic marble are characterized by extremely low amounts of crustal material (such as Al, Ti, Zr, Hf) and high Y/Ho ratios (46-66), also implying a pure marine chemical origin. Excluding some contaminated samples, the rest of the graphite-bearing marble samples display similar features of the dolomitic marble. Significant positive Ce anomalies and high light to heavy REE (Pr/Yb(SN)) ratios in both dolomitic marble and graphite-bearing marble are essentially consistent with the 2.2-2.1 Ga carbonates from the Guanmenshan Formation of the Liaohe Group in the NE Sino-Korean Craton. Combined with the Ce anomalies in the BIF samples, we consider that the seawater when the upper Taihua Group deposited was redox-stratified from oxic shallow water to deeper anoxic water. Besides, the graphite-bearing marble record coeval surface water in the column that was enriched in nutritive materials and beneficial to microbiology and high productivity. Moreover, the early Paleoproterozoic IFs in the Songshan Group and the Lüliang Group in the NCC also exhibit significant both positive and negative Ce anomalies and enrichment of redox sensitive elements. These evidences, therefore, suggest that redox-stratified seawater occurred extensively during the GOE.

Preliminary observations of fulgurites: prebiotic sources of reduced phosphorus on early Earth

DongJun KIM[1]*, Metropolitan Seoul Center, Korea Basic Science institute/ Kangwon National University (donzon94@kbsi.re.kr)
Sae Jung Chang [2], Metropolitan Seoul Center, Korea Basic Science institute
Kideok Kwon [3], Department of Geology, Kangwon National University
Ruth E. Blake[4], Department of Earth and Planetary Sciences, Yale University
Matthew A. Pasek [5], School of Geosciences, University of South Florida

Abstract

Phosphorus (P) occurs on Earth primarily in fully-oxidized form as phosphate (HPO_4^{2-} at pH 8, represented here by PO_4 to encompass the range of protonation states and ion pairs) with a valence of 5+ and is conventionally thought of as having no significant redox chemistry. However, recent discoveries have shown that phosphorus (P), not as phosphate (PO_4 with P^{5+}) but as phosphite (PO_3 with P^{3+}), could have been a major source of phosphorus for pre-biotic synthesis and major nutrient in early pre-oxygenated oceans (Pasek, 2008).

The highly energetic nature of lightning causes the abiotic reduction of phosphate and provides reduced P-compounds to modern near-surface earth environments. Pasek and Block (2009) proposed cloud-to-ground high energy lightning strikes as an important source of reduced-P (both phosphide/Fe_3P and phosphite). Fulgurites, commonly composed of glass and fractured minerals, are the product of cloud-to-ground lightning strikes. Fulgurites could have been a significant source of prebiotic and bioavailable phosphorus instead of apatite, known as the most common form of phosphate minerals on Earth surface environment (Hess et al., 2021).

The goal of this study is to determine oxygen isotope systematics of phosphorus redox chemistry. Here, we will present preliminary mineralogical and chemical compositions of fulgurites (Type III) from La Paz County and Yuma County, Arizona, in addition to their oxygen isotopic composition of natural phosphite (PO_3) from fulgurites to evaluate initial prebiotic oxygen isotope signatures of phosphite (PO_3) as well as co-evolution of these prebiotic oxygen isotope signatures and life.

The coming and going of banded iron formation

Bing SHEN[1]*, Peking University (bingshen@pku.edu.cn)
Ruimin Wang[2], Peking University

Abstract

Banded iron formations (BIFs), featured by rhythmic Fe-rich and Si-rich mm- to cm-thick laminae, is the Archean and Paleoproterozoic landmark, and did not show up in the rest of Earth's history except for a brief reprise in the Cryogenian global glaciations (~0.7 Ga, billion years ago). The up and down of BIFs have been attributed to the wax and wane of marine Fe2+ inventory, while Si precipitation, as a background, was decoupled with the Fe cycle. However, the mid-Proterozoic ocean was predominantly ferruginous (Fe2+ rich), and non-BIFs iron formations (IFs) are not uncommon, casting doubts on the Fe-depletion as the primary reason for the shutdown of BIFs factory. Here, we show genetic relationships between Fe, Si, and P mineral phases, suggesting the coupled Fe-Si-P cycles in the BIF formation. We propose that rhythmic depositions of Fe-rich and Si-rich laminae may reflect cyclic fluctuations of Fe redox cycles, consisting of Fe2+ oxidation in seawater and microbial FeOOH reduction in sediments. FeOOH shuttled seawater Si and P into sediments, and a large Si flux that is required for BIFs only occurred in Si-rich oceans. The disappearance of BIFs in mid-Proterozoic might result from declines of seawater Si content due to the evolution of eukaryotes and mild oxygenation of the atmosphere, enhancing Fe redox cycles in globe. Reoccurrence of BIFs might result from a sluggish Fe redox cycle, allowing accumulations of Fe and Si, in anoxic and organic-lean Snowball Earth oceans. The post-glacial oxygenation restricted the Fe redox cycle predominantly within sediments, and the epoch of BIFs eventually and ultimately ended. This model highlights the essential role of microbial activities in BIFs formation, implying BIFs as a biosignature for life in early Earth and other planets.

Abstract

Phosphorus is an essential nutrient element for life and its availability is one of the limiting factors for primary productivity. Recent studies have highlighted the roles of clay minerals in delivering phosphorus by surface adsorption to the early ocean under the anoxic and ferruginous conditions of early Earth. One critical finding from the adsorption experiment is that a large amount of phosphorus adsorbed by clay minerals could be back released when transitioning from acidic and diluted river water to more alkaline and saline seawater, which could greatly promote early biological productivity. However, these adsorption experiments do not consider the potential influence of high contents of dissolved ferrous iron (Fe2+) in early anoxic waters on the adsorption. In this study, we conducted batch adsorption experiments under anoxic conditions to simulate the adsorption of phosphate by kaolinite in Archean marine and river water, emphasizing the effect of dissolved Fe2+. Our preliminary results show that the adsorption of phosphate onto kaolinite was greatly promoted in the presence of moderate levels of dissolved Fe2+ relevant to the early seawater, thus challenging the previously proposed “kaolinite shuttle” hypothesis that emphasizes the role of clay minerals as carriers for transporting phosphorus from river to seawater on early Earth. This work was financially supported by Internal Grants for HKU Faculty Start-up Fund (000250348).

Jesper Allan Frederiksen[7], University of Copenhagen

Abstract

The Ediacaran-Cambrian transition is a key interval of Earth's history, when some of the most important biological, tectonic, climatic and geochemical shifts changed the surface of the planet unidirectionally and set the stage for the Phanerozoic. To test how interlinked the variations in one of those spheres were connected to the others, proxy tools that can be used to identify the possibly changes in key variables such as nutrients and oxygen availability need to be applied on fossil-bearing successions. This approach has proven to be the most appropriate permitting to infer the possible influence of paleoenvironmental factors on the development and diversification of early complex life. The Ediacaran mixed siliciclastic carbonate Tagatiya Guazú Formation, Itapucumi Group, covers the southern part of the Rio Apa block in northeastern Paraguay and is interpreted as deposited in a shallow rimmed ramp bordering southwestern Gondwana. Due to the presence of an abundant and diverse late Ediacaran fossil assemblage and a robust stratigraphic sedimentological and isotopic background, this unit is an ideal basin to test the hypothesis of nutrient and redox control on such biological communities, as it contains microbialites with in-situ Cloudina and Corumbella remnants, locally associated with ichnofossils such as Archaeonassa. We apply two carbonate-based modern isotopic techniques to track, respectively, redox and nutrient conditions during deposition of the Taguatiya Guazú Formation: Cr and Cd isotopes, along with novel trace elements and Sr isotope data, in two different sections (PLI and PLIII). The carbonate samples show slightly MREE(Middle Rare Earth Element)-enriched patterns and Y/Ho ratios around 26-32. Cr isotopes are fractionated throughout the two studied sections, with authigenic delta53Cr values ca. 0 to 0.5‰. The levels containing trace fossils are especially enriched, reaching as high as ca. 1‰, indicating important oxidative weathering in the source areas. Conversely, Ce anomalies are muted throughout most of the two sections (Ce/Ce* around 0.9), but in the levels containing trace fossils they plunge down to ca. 0.67, indicating important Ce cycling and manganese oxide precipitation. Authigenic Cd isotopes show variable fractionation, reaching delta114Cd values as high as 5.57‰; in the trace-fossil bearing levels, delta114Cd is around 4‰. These values indicate increased uptake of Cd, among other nutrients, into phototrophic plankton, supporting high levels of primary productivity. Finally, 87Sr/86Sr is homogeneous around 0.7086 for section PLI and around 0.7090 for section PLIII, indicating typical late Ediacaran seawater signatures. Our results shed light into the biogeochemical cycles

during the rise of metazoans, and suggest that the first complex organisms thrived in shallow oxygenated seas under favorable nutrient conditions that fueled trophic chains during the final amalgamation of Gondwana. Ediacaran diamictites and glaciation in North China

Yongqing LIU[1]*, Institute of Geology, CAGS (liu_cags@126.com)
Hongwei Kuang[2], Institute of Geology, CAGS
Xiaoshuai Chen[3], Institute of Geology, CAGS
Yuchong Wang[4], Institute of Geology, CAGS

Abstract

The Ediacaran glacial deposits are developed in the North China Craton, Tarim Craton and the microblocks among them, where they can extend for 3000 km from east to west. However, the chronology, scale of glaciation, paleogeographic reconstruction and tectonic setting are still controversial. Based on the spatial distribution, stratigraphy and sedimentary sequence, sedimentary environment and sedimentary facies of the Ediacaran diamictites in northern China, combined with previous literatures at home and abroad, the above issues related to Ediacaran glaciations are systematically analyzed. This paper revealed that during the Ediacaran, there should have been a glaciation of younger than 580 Ma (Gaskiers) all over the world. The age constraints of the Ediacaran glaciations in northern China were placed between 583 and 551 Ma, and the subglacial, periglacial, and proglacial sedimentary facies can be identified; these form the diamictite from subglacial to proglacial, followed by normal marine sedimentary sequences vertically (in ascending order), in line with the sedimentary response pattern of continental glacier (ice sheet). The Ediacaran diamictites and glacial erosional forms are widespread distributed globally, and the cap dolostones can be developed above the diamictites, exhibiting sedimentary structures similar to the Cryogenian cap dolostones, but the carbon isotope characteristics of them are not the same. This paper speculates that the Proto-Tethys Ocean and its surrounding continents may have developed continental ice sheets during the Ediacaran, but there was no affinity between the Asian blocks and the Gondwana supercontinent. The results provide geological evidences for the global paleogeographic reconstruction and tectonic setting restore of the Ediacaran period.

Was there a palaeo-ocean in South China during the late Tonian to Cambrian? – Evidence from provenance variation across the Xiang-Gui-Yue Basin

Yang TIAN[1]*, Wuhan Center, China Geological Survey (Geosciences Innovation Center of Central South China), China (41834572@qq.com)
Zhijun NIU[2], Wuhan Center, China Geological Survey (Geosciences Innovation Center of Central South China), China
Wei WANG[3], School of Earth Sciences, State Key Laboratory of Geological Processes and Mineral Resources, China University of Geosciences, China

Abstract

The South China Block was formed by the amalgamation between the Yangtze and Cathaysia blocks, after the closure of the South China Ocean. However, the closure time of this ocean is still controversial with ages proposed ranging from Neoproterozoic to early Paleozoic. Provenance analysis of siliciclastic rocks outcropped at the Xiang-Gui-Yue (XGY) Basin across the potential suture zone between the Yangtze and Cathaysia blocks, was used to reveal whether the two blocks were separated by a palaeo-ocean during late Tonian to Cambrian. An obviously provenance transition from the Yangtze-derived (dominated by ~0.8 Ga zircons) to the Cathaysian-derived (dominated by ~0.98 Ga zircons) detritus was founded in the whole XGY Basin, while this transition happened gradually changed at Cryogenian, Ediacaran and Cambrian respectively, from the southeast to northwest parts of the XGY Basin. Cathaysian-type detritus continued to transport towards northwestward as probably caused by uplift of the Cathaysia Block. Collectively, the XGY Basin was mainly fed by Yangtze-derived detritus during late Tonian, while the Cathaysia-derived sediments became prevail since then. In details, the Cathaysian-derived detritus arrived at the southeastern, central, northeastern part of the XGY Basin at Cryogenian, Cambrian, and Ordovicain respectively. This provenance change argues against the existence of a broad palaeo-ocean during the late Tonian to Cambrian in the South China. Combined with sedimentary sequence and associated volcanism, the XGY Basin was a rift basin until ca. 660 Ma, following by the development of a passive margin basin during Ediacaran-early Cambrian and a foreland basin after the middle-late Cambrian.

Ediacaran-Cambrian transition events in the peninsular India: Insights from isotope stratigraphy and geochronology of Bilara carbonates, Marwar Supergroup

Bivin Geo GEORGE[1]*, Indian Institute of Technology Bombay (bivingeo@gmail.com)
Jyotiranjan RAY[2], Physical Research Laboratory

Abstract

Peninsular India hosts a number of Proterozoic sedimentary successions; of which some continue well into the Cambrian. These successions contain largely undeformed and unmetamorphosed marine carbonate units which are believed to have recorded physical and/or chemical evidence for the important global events of the Proterozoic and early Paleozoic such as 'snowball Earth' glaciations, Shuram δ13C excursion, terminal Ediacaran and early Cambrian extinctions. However, the attempts to unravel such information from these rocks have been limited. In search of chemical and physical evidence of some of these events, we studied Bilara Group, the carbonate unit of late Neoproterozoic – early Paleozoic Marwar Supergroup.

87Sr/86Sr of the limestone formation of the Bilara Group shows variation from 0.70810 to 0.70916 indicating an early Cambrian (520 - 539 Ma) depositional age for the Group. The 207Pb/204Pb-206Pb/204Pb isochron of the same limestone formation yielded an age of 537 ± 19 (2σ) Ma further confirming the age estimate suggested by 87Sr/86Sr-stratigraphy. δ13C stratigraphy of the Bilara Group revealed negative excursions of magnitudes ~6‰ and ~7‰, respectively, in the middle and lower parts of the Bilara Group, respectively. Since these δ13C anomalies are observed through-out the Marwar Basin that was connected to global oceans, it is likely that they represent temporal changes in the seawater chemistry. Using the principles of δ13C stratigraphy and the available geochronological information, we correlate the middle Bilara anomaly to Shiyantou carbon isotope excursion (SHICE) and the lower one as basal Cambrian carbon isotope excursion (BACE). δ13C and 87Sr/86Sr stratigraphic records along with Pb-Pb age suggests that the Ediacaran-Cambrian transition in the Marwar Supergroup is likely contained within the Bilara Group, and it is the first such report from the peninsular India.

Abstract

The Neoproterozoic deposits in the western portion of the São Francisco basin, which was contiguous with the Congo craton, are represented by the Jequitaí Formation and the Bambuí Group. The Sete Lagoas Formation represents the basal unit of the Bambuí Group and consists of a sequence of carbonate-dominated sediments in the São Francisco basin. Even though five formations have been formalized within the Bambuí Group, the type sections of these lithostratigraphic units were never formally described. The International Stratigraphic Guide establishes that a formal lithostratigraphic unit must have a type locality and a stratotype section with a clear characterization. As a stratotype was never described for the Sete Lagoas Formation, a proposal of a lectostratotype is highly recommended. Additionally, the designation of a lectostratotype section is a possibility to complement the definition of a lithostratigraphic unit. Due to the lack of a formal proposal for a stratotype section for the Sete Lagoas Formation, the Rei do Mato cave section is discussed as a potential candidate for a lectostratotype designation. This section is located inside the borders of the Gruta Rei do Mato Conservation Unit, Sete Lagoas County, Minas Gerais State, southeastern Brazil, Datum WGS84, 23K, 575103 mE, 7844059 mN (UTM). This section is 125 meters thick, and the upper boundary with the Serra de Santa Helena Formation outcrops. However, the basal boundary of the Sete Lagoas Formation with the underlying lithostratigraphic unit is not exposed in this area, and the rocks of the Sete Lagoas Formation rest on top of a Paleoproterozoic gneiss–migmatite basement. The section consists predominantly of limestones, with little or no contribution of siliciclastics. The main lithologies are pure calcarenites, light to dark gray, with variable grain size, and presenting a high diagenetic grade. In the basal and intermediate portion of the section, sedimentary structures such as hummocky and swaley cross-bedding, soft-sediment deformation comprising synforms, and convoluted bedding occur. This lithofacies association indicates deposition below the fair-weather wave base, in a transitional environment influenced by storms, and associated with a sloped carbonate ramp with a high accumulation rate. In the upper portion of the section, the lithofacies display a greater amount of low-angle, tabular cross-lamination, climbing ripples, herringbone cross-stratification, and the occurrence of bifurcated columnar stromatolites. Such morphotype of microbialites was classified as possibly belonging to the Genus *Gymnosolen* Steinmann, 1911.

The distribution of these stromatolites varies laterally, depending on the paleoecological conditions, possibly representing a stromatolitic internal carbonate ramp, influenced by waves or tides. The interval above the stromatolites presents a more significant contribution of siliciclastic material, consisting of marls overlain by massive laminated siltstones, representing the transition to the Serra de Santa Helena Formation. This boundary can represent a major marine transgression associated with paleoenvironmental changes, in which the platform becomes influenced by siliciclastic materials from the craton.

Orbitally-paced carbon-isotope excursion and sedimentary rate during the middle-late Cambrian

Jixuan WANG[1]*, China University of Petroleum (East China) (1079299440@qq.com)
Guanghui YUAN[2], China University of Petroleum (East China)

Abstract

Important events occurred during the Cambrian, including extinction events, biotic turnover, eustatic sea-level events, carbon isotope excursion, and climatic perturbations. Due to the lack of data from the Cambrian, a valid temporal framework for the Cambrian and major events cannot be constrained, and the key forcings of sea-level change on the million-year (Myr) scale remains controversial. Here, the high-resolution gamma-ray logs (GR) and carbon isotope of a Well LT are utilized to conduct cyclostratigraphic analysis of the middle-late Cambrian Drumian -Stage10 Xixiangchi Formation of the Well LT in South China. A ~17.992 Myr-long high-resolution astronomical time scale across Drumian -Stage10 is developed by astronomical tuning of gamma-ray logs to the stable 405-kyr long orbital eccentricity cycles. The Myr-scale sea-level fluctuations in the middle-late Cambrian are reconstructed through the sedimentary noise modeling of the 405-tuned GR series. The correlation of filtered ~2.2 Myr cycles of sedimentary noise curves with the filtered ~2.2 Myr long orbital eccentricity modulation cycles of carbon isotope excursion demonstrates that the sea-level variations of ~2.2 Myr long orbital eccentricity modulation cycles may be a primary driver for carbon isotope excursion during the middle-late Cambrian period, further contributing to the late Cambrian SPICE (Steptoean Positive Isotopic Carbon Excursion). Sedimentation rate evolution in carbonates of the 405-kyr long orbital eccentricity cycle time model for the middle-late Cambrian may be related to mineral content, sea-level variations, and carbon isotope excursion. Our results enhance knowledge of the connection between Myr-scale sea-level variations and carbon isotope excursion and provide new empirical constraints on the deep-time evolution of sedimentation rates.

Abstract

The end–Ordovician Glaciation (also known as Hirnantian Glaciation) was one of the three major glacial events in the Phanerozoic. Although this glaciation lasted for a short time, it had a significant impact on Earth's environment. This glaciation triggered the dramatic fluctuations of isotopic composition of ocean water and the redox state of the seafloor, along with the end-Ordovician Mass Extinction. To figure out how the glaciation affected the biological evolution processes and the changes in seawater chemical condition, it is necessary to explore the development processes of glaciation and the glacio–eustatic cycles. Over the past decades, it has been recognized that the end-Ordovician Glaciation consisted of multiple ice sheet expansions and retreats.

Four sections of scientific drill cores, the Wells HY–1, HG–1, SH–1 and YW–1 in South China are selected as the main material for the present study. These wells are close to four classic outcrop sections of near-shore to offshore facies on the Yangtze Platform, i.e., the Honghuayuan, Huanggexi, Shuanghe, and Wangjiawan sections, which provides a precise correlation between the wells and the outcrop sections. Continuous, non-destructive, high-resolution core scanning (34770 data points) of element concentration, measurements of major and trace element concentration (268 samples), and analyses of organic carbon isotopic composition and TOC (333 samples), as well as sedimentary facies analyses (67 thin sections), were carried out for a total length of 34.77-meter fresh drill cores with depositional age ranging from the Katian (Ordovician) to the Rhuddanian (Silurian).

The results of microfacies analyses, and the chemical index of alteration (CIA), silicon-aluminum ratio (Si/Al), zirconium-aluminum ratio (Zr/Al) and sum of aluminum-potassium-titanium (Al+K+Ti), show that the end Ordovician Glaciation began at the end of Katian (the upper Paraorthograptus pacificus Biozone) and terminated in the late Hirnantian (the lower-middle part of the Metabolograptus persculptus Biozone), represented by a large glacio–eustatic cycle. The results also show that the glaciation consists of three secondary glacio–eustatic subcycles as recorded in South China, the first occurred at the Katian–Hirnantian transition (the topmost Paraorthograptus pacificus Biozone to the basal Metabolograptus extraordinarius Biozone), the second in early Hirnantian (the upper part of the Metabolograptus extraordinarius Biozone to the basal Kuanyinchiao Bed), and the third in late Hirnantian (the upper part of the Kuanyinchiao Bed

to the lower Metabolograptus persculptus Biozone), which likely represents the glacial maximum . The glacio–eustatic cycles in South China during the end-Ordovician Glaciation are consistent with those cycles recognized by tillite depositions and the glacio–eustatic cycles identified elsewhere.

Abstract

There are relatively few sedimentological studies on the Cryogenian in the northwestern Yangtze Craton, especially in the Chengkou area of Dabashan Mountain, and whether the Cryogenian Muzuo/Mingyue and Dai'anhe formations have glacial sedimentary characteristics is also lack of detailed sedimentological interpretation, which restricts the understanding of sedimentary evolution process of the Cryogenian in the Yangtze Craton, and is not conducive to the determination of the sedimentary stratigraphic framework and regional correlation of the Cryogenian. In this paper, four typical Cryogenian sections in the Chengkou area are selected to carry out a detailed stratigraphic and sedimentological study, and the glacial sedimentary marks such as the gravels with glacial striae, dropstone, and subglacial soft sedimentary deformation are identified to prove the glacial genesis of the Dai'anhe and Muzuo/Mingyue formations. The facies of continental, periglacial and marine glacial are also discerned. On this basis, according to the rock assemblages, sedimentary characteristics, structure of stratigraphic succession, geochemical indexes (such as chemical index of alteration) and detrital zircon U-Pb age, the Dai'anhe Formation is divided into two members. The first member is correlated with the Gucheng Formation, the second member is correlated with the Datangpo Formation, and the Muzuo/Mingyue Formation is correlated with the Nantuo Formation. Further, through regional correlation, the stratigraphic framework of the Cryogenian in the northwestern Yangtze Craton is re-determined, and can be correlated with that of in the adjacent Shennongjia area and southeastern Yangtze Craton. The sedimentary co-evolution process of the Cryogenian in the Chengkou-Shennongjia areas is: during the Stuartian glacial period, the glacial transgressive-regressive cycle from the glaciomarine to the land and then to the glaciomarine developed, and then the extensive transgression of the interglacial period formed a lagoon environment represented by carbonaceous silty mudstone. With the global temperature falling again, the Marinoan glacial period was triggered, which was reflected in the multiple glacial dynamic evolution from the glaciomarine ice-proximal to the ice-distal environment, and accompanied by the opening of the ice sheet and finally to the end of the Cryogenian. The research has determined the correlation and subdivision of the Cryogenian in the northwestern Yangtze Craton, providing new basic data and important basis for the correlation of the Cryogenian in the Yangtze Craton.

Sedimentology and timing of the Klipheuwel Group, South Africa – anatomy of a Cambrian-Ordovician failed rift in southwest Gondwana

Ruan Francois RAATH[1]*, Stellenbosch University (18971601@sun.ac.za)
Cameron PENN-CLARKE[2], University of the Witwatersrand
Clarisa VORSTER[3], University of Johannesburg
Alexander F.M. KISTERS[4], Stellenbosch University

Abstract

Detrital geochronology of 700 zircon grains and in-depth sedimentological characterisation of the upper Cambrian, coarse clastic deposits of the Klipheuwel Group provide new evidence for the onset of rift-type tectonics shortly after Gondwana amalgamation. Isolated Klipheuwel exposures in southern South Africa reveal the presence of at least two distinct depocentres (informally: “northern”- and “southern” Klipheuwel depocentres), highlighting independent sedimentation controls responsible for the deposition of the Klipheuwel Group in an extensional setting.

Deposits in the northern depocentre are characterised as “braided sheets” with lithologically lateral continuous beds reaching maximum thicknesses of 400 m that onlap the Pan-African basement. Here, palaeo-flow vectors suggest southeastern palaeocurrent indicating a north-northwestern source of detritus. Detrital zircon geochronology shows distinctly bimodal distribution with peaks at ca. 540 Ma and 1050 Ma. Older zircon populations (ca. 1050 Ma) indicate the influence and detrital input from the Namaqua-Natal Metamorphic Belt (1200 – 950 Ma) to the immediate north, whilst the younger detrital population (ca. 540 Ma) is likely derived from the local Cape Granite Suite (555 – 515 Ma) and/or South American granites from the Pampean Belt (580 – 510 Ma).

Deposits in the southern depocentre are characterised as “braided channels” with rapid facies changes over short distances. These deposits are fault-bounded and preserved in half-graben structures, likely reutilizing, and reactivating older Pan-African basement shear zones. In contrast to the northern depocentre, deposits in the southern depocentre are thicker (> 2000 m) with a northwestern palaeocurrent indicating a south-southeastern source of detritus. Here, detrital geochronology shows distinctly unimodal signature with a population peak at ca. 530 Ma, which likely reflects local derivation of the directly underlying Cape Granite Suite (555 – 515 Ma). The source of six younger zircons, ca. 510 – 488 Ma, from the southern depocentre, is enigmatic in origin when considering only local source terranes but may have potential ties to middle- and late-Cambrian granitoids on neighbouring continental fragments (i.e. North Patagonian Massif and Deseado Massif).

The maximum depositional age of ca. 488 Ma, for the Klipheuwel Group, straddles the Cambrian-Ordovician transitional boundary and notably coincides with the late-Cambrian, early-Ordovician emplacement of coast-parallel mafic dykes in Namaqualand to the immediate north that are tentatively related to mafic, magmatic underplating and a possible mantle plume. Other Cambrian-Ordovician deposits from South America, (Nahuel Niyeu and the Olta Formations) display similar geochronological zircon populations and similar lithological characteristics, which could be

considered as regional, rift-related depositional equivalents, although linkages remain tenuous. This points to continental scale extensional tectonics immediately following Gondwana amalgamation, conducive to subsequent deposition of the far more extensive Cape Supergroup in South Africa.
This study of the Klipheuwel Group interprets numerous new detrital zircon ages and reevaluates the sedimentology of these enigmatic depocentres, both locally and regionally, in a post-Gondwana, pre-Cape setting. Partly fault-controlled rift-type sedimentation, coinciding with rift-parallel dyke formation and mafic underplating as well as correlations with sequences in South America around the Cambrian-Ordovician boundary, implies that the Klipheuwel Group likely represents depositional relics of the regional Cambrian-Ordovician failed rift.

Application of the Wavelet Transform coupled with Fischer plots and INPEFA in Sequence Stratigraphy

Yu ZHANG[1]*, School of Geosciences, China University of Petroleum (East China), Qingdao, 266582, ShandongPR China (zhangyu136097@163.com)
Taixun Liu[2], School of Geosciences, China University of Petroleum (East China), Qingdao, 266582, ShandongPR China
Jie Wen[3], School of Geosciences, China University of Petroleum (East China), Qingdao, 266582, ShandongPR China

Abstract

In recent years, the exploration and development of deep-water petroleum resources in the South China Sea region has shown significant potential for increasing reserves and production. In offshore areas with few wells, the limited availability of paleontological fossils and rock data makes it challenging to accurately classify stratigraphic sequences using traditional methods. This difficulty hinders the exploration and development of oil and gas reservoirs. To accurately characterize the transverse distribution of sand bodies and improve the prediction accuracy of sand bodies, the second-order sequence La was divided by sequence stratigraphy in this study. Based on traditional stratigraphic division methods research, such as seismic interpretation, stratigraphic correlation, and core observation, INPEFA and wavelet transform can be utilized to analyze the gamma ray (GR) curve. This process can enhance the inflection points and changing trends of the curve while minimizing human intervention. A method combining the Continuous Wavelet Transform (CWT) and Fischer plots is proposed to identify sequence boundaries and achieve high-resolution stratigraphic correlation. In this study, the Morlet wavelet was selected as the optimal wavelet mother function due to its excellent periodicity and significant variability. Based on the modulus average value of the GR of the Morlet wavelet at various scales, it is compared with core and well-logging data. The optimal scale factors are determined to be 40,20, and 10, corresponding to the long-term cycle, the medium-term cycle, and the short-term cycle, respectively. By analyzing the sequence characteristics of a large number of core segments and the corresponding CWT results (wavelet coefficient curve and time-frequency energy spectrum), three main types of sequence cycles (progradational, accretive, and regressive) are identified and applied to the entire well section in the study area. Based on the division of the short-term cycle and the identification of the medium-term cycle, the Fischer plot is used to determine the long-term cycle and validate the results using the CWT. Finally, comparing the application range and effectiveness of INPEFA and wavelet transform.

The results show that La can be divided into 5 long-term cycles,13 medium-term cycles, and 38 short-term cycles using maximum entropy spectral analysis and wavelet transform. The high-resolution sequence stratigraphy, which is based on the combination of the Continuous Wavelet Transform and Fischer plots, demonstrates agreeable practicality. It can intuitively identify the relative changes in sea level position and is consistent with the results of sea level analysis obtained from core samples and well-logging curves. The inflection point and the trend change of

the INPEFA curve are more pronounced at the sequence boundary with a larger span, making it suitable for determining third- and fourth-order sequences. The wavelet transform can adjust the scale factor to recognize the internal cyclicity of logging curves, making it more suitable for identifying fourth- or fifth-order sequences. This method can effectively establish the isochronous stratigraphic framework of the clastic rock reservoir, similar to the approach used in this study. It has significant promotional value for identifying sequences in similar oil fields and can also improve the efficiency of geological research processes.

Geochronological constraints of high-grade metasedimentary rocks of the Italva and Costeiro basins: Reconstructing the Outer Magmatic Arc System of the ribeira belt, SE Brazil

Caroline de Araujo PEIXOTO[1]*, UERJ (caprdj@gmail.com)
Marcela Lobato[2], UERJ
Natalia Cota[3], UERJ
Monica Heilbron[4], UERJ
Ivo Dussin[5], UERJ
Elton Dantas[6], UNB

Abstract

U-Pb provenance studies of the magmatic arc-related basins of the Ribeira Orogen are essential to unravel the depositional history and the paleogeography prior to the diachronic collision that has resulted in Neoproterozoic to Cambrian Western Gondwana assembly. This work brings new geology and LA-ICPMS data from metasedimentary units and felsic to mafic magmatic rocks that compose the Outer Magmatic Arc System (OMAS) in the Ribeira segment of the Araçuaí-Ribeira Orogenic system (AROS), contributing to unravel the construction of the West-Gondwana supercontinent. The OMAS evolution started in Tonian time (860–790 Ma) as the juvenile intraoceanic Serra da Prata arc and evolved into the immature continental Rio Negro arc during the CryogenianEdiacaran times (650–620 Ma). The long-term subduction revealed the coeval stages development of arcrelated basins. In the first Tonian stage, basin development is associated with the Italva group, divided into two sequences representing both fore and back-arc settings. The forearc sequence (Euclidelandia unit) comprises meta-psammitic sedimentary rocks with a single provenance source from the SP arc (peaks at 812 Ma and 828 Ma). The back-arc sequence (Sao Joaquim unit) consists of marbles with MORB-like interlayered amphibolites (ca. 831 Ma) bracketing the maximum age of carbonatic platform deposition. On the other hand, the younger Cryogenian to Early Ediacaran Costeiro back-arc basin is represented by three units of the S˜ ao Fid´elis group. The proximal Macuco unit, comprising meta psammitic rocks with marble, yielded a bimodal provenance distribution (852–815 Ma; 643–634 Ma), which reflects only the SP and RN magmatic arcs sources. The pelitic distal Upper and Lower units point out multimodal sources, coming from the SP-RN arc-rocks (ca 950–734 Ma; ca. 693–621 Ma) and Archean to Mesoproterozoic sources (ca. 3.12–3.0 Ga; 2.98–2.49 Ga; 2.29–1.50 Ga; 1.49–1.01 Ga), derived from ancient cratonic blocks located eastern wards, in African side. All units of the OMAS recorded two metamorphic episodes, with the oldest M1 (ca. 600–590 Ma) related to the collision of the OMAS against the Inner Magmatic Arc System (IMAS) and the younger M2 (ca. 545–533 Ma) that resulted from the final docking of the Cabo Frio terrane (Angola block) and finally closed the OMAS back-arc basin. Data obtained reinforces the long-term E-verging subduction that built the OMAS.

The selection of the Global boundary Stratotype and section (GSSP) for the Carboniferous Moscovian Stage

Keyi HU[1]*, Nanjing University (kyhu@nju.edu.cn)
Xiangdong Wang[2], Nanjing University

Abstract

The Carboniferous System includes seven stages, namely the Tournaisian, Visean, Serpukhovian, Bashkirian, Moscovian, Kasimovian, and Gzhelian stages. Except for the Tournaisian, Visean, and Bashkirian stages, the Global boundary Stratotypes and sections (GSSPs) of the remaining four stages have not been established. The Moscovian Stage was originally named in the Moscow Basin, Russia in 1890, and was selected as an official Carboniferous stage for the International Chronostratigraphic Chart at the beginning of this century. However, the boundary marker or the index fossil for the base Moscovian has not been selected yet although the Task Group has studied many potential boundary markers across different regions during the past two decades. Currently, conodonts Diplognathodus ellesmerensis Bender and Declinognathodus donetzianus Nemirovskaya are considered to have a higher potential for recognition of the Bashkirian-Moscovian boundary and international correlation. The Naqing section, South China, and the Basu section, South Urals, Russia are candidate sections for the GSSP of the Moscovian Stage. Here, we evaluate many aspects of the two potential boundary markers, e.g., species concept, evolutionary pathway, geographic distribution, First Appearance Datum (FAD), and auxiliary markers to determine which has a higher potential for marking the global Bashkirian-Moscovian boundary. The FAD of Diplognathodus ellesmerensis is close to the traditional BMB in its type area. If it is used to mark the base of the global Moscovian Stage, Diplognathodus ellesmerensis would maintain the traditional concept of the Bashkirian-Moscovian boundary. Diplognathodus ellesmerensis has been found worldwide, and its lineage is well documented. Therefore, Diplognathodus ellesmerensis meets the requirements for a boundary marker in a part of the geological column where international correlation is very difficult.

The Middle-Late Pennsylvanian Event: timing and mechanism

Yixin WANG[1]*, Nanjing University (211830014@smail.nju.edu.cn)
Keyi HU[2], Nanjing University
Xiangdong WANG[3], Nanjing University

Abstract

Driven by the Late Palaeozoic Ice Age (LPIA) and climate dynamics, drastic biotic changes have been recorded in both marine and non-marine realms during the Middle-Late Pennsylvanian, i.e., Moscovian-Kasimovian (ca. 307-303.7 Ma). However, the timing, mechanism, and amplitude of these events are not well understood due to rare records of the Pennsylvanian rock successions, and difficult international correlations caused by frequent glacio-eustatic transgressions and regressions during the LPIA. This study focuses on the late Desmoinesian extinction Event and the conodont biodiversification Event in the marine realm. Both happened close to the Middle-Late Pennsylvanian boundary interval and are referred to as the Middle-Late Pennsylvanian Event. In southern Guizhou, South China, carbonate successions containing abundant conodonts were deposited at the slope to basinal environments during the Pennsylvanian, providing great opportunities to study those events. Focused on the Middle-Upper Pennsylvanian boundary interval, the Naqing, Shanglong, and Narao sections are studied here. We present an integrated stratigraphic framework including conodont biostratigraphy, strontium and oxygen isotope of conodont apatite, and carbon isotope of bulk rock across the Middle-Upper Pennsylvanian boundary interval. A total of 11 conodont zones, namely the late Moscovian Idiognathodus podolskensis and Swadelina sp. A zones, the Kasimovian Sw. subexcelsa, Sw. makhlinae, I. heckeli, I. turbatus, I. magnificus, I. guizhouensis, Heckelina eudoraensis, and I. naraoensis zones, and the Gzhelian H. simulator Zone, are recognized. Notably, the bases of the Sw. subexcelsa and I. heckeli zones mark the traditional and the alternative Moscovian-Kasimovian boundaries, respectively, while the base of the H. simulator Zone marks the Kasimovian-Gzhelian boundary. δ13C and 87Sr/86Sr curves in the Naqing, Narao and Shanglong sections are consistent, showing three phases of environmental change during the late Desmoinesian extinction Event and the conodont biodiversification event. During the first phase, a negative shift of δ13C is recorded in the Swadelina sp. A Zone, while no significant change was documented in 87Sr/86Sr. In the second phase, a negative shift of δ13C in the Swadelina subexcelsa Zone was well recorded, in which 87Sr/86Sr dropped by ~0.0001. In the last phase, positive excursion of δ13C is correlated with a rise in 87Sr/86Sr. The first phase is well correlated with the biomes change in rainforest, which reduced plant productivity but had no significance in weathering probably attributed to vegetation cover being unchanged. In the second phase, increasing climate aridification caused changes in rainforest, which led to productivity reduced again. Furthermore, the negative shift in 87Sr/86Sr indicates continental weathering weakened during this phase, which may be attributed to the desertification in the equatorial region by the aridification. In this case, nutrient input from rivers was reduced, which may affect the shallow-water environments and partly contribute to the

late Desmoinesian extinction Event. In the last phase, δ18O values start to drop, which means temperature started to return to normal level. The productivity and coverage of vegetation recovered, which both led to the positive shifts in δ13C and 87Sr/86Sr curves. Regained continental weathering and river runoff increased nutrient input into the ocean, which could contribute to the conodont biodiversification.

Phylogeny and paleobiogeography of the Carboniferous conodont genus *Gnathodus*

Wenqi WANG[1]*, Nanjing University (wqwang@smail.nju.edu.cn)
Keyi HU[2], Nanjing University
Xiangdong WANG[3], Nanjing University

Abstract

Conodonts are regarded as an important biostratigraphic tool for the subdivision and correlation of global marine strata deposited during the Paleozoic and Triassic. For the Carboniferous, various conodont zonations have been established in different regions due to palaeobiogeography. The conodont genus *Gnathodus* arose in late Early Mississippian and disappeared in early Early Pennsylvanian, and is one of the most important taxa for Carboniferous biostratigraphy. Nearly half of the Mississippian conodont zones are defined by the first appearances of certain *Gnathodus* species/subspecies. The genus *Gnathodus* contains numerous species, which generally can be divided into three earlier groups, the *G. delicatus*, *G. typicus*, and *G. punctatus* groups, and two later groups, the *G. bilineatus*, and *G. girtyi* groups. Currently, the evolutionary relationships between these groups and the morphological changes during the evolutionary process are not fully understood, which sometimes leads to inaccurate correlations when using *Gnathodus*-based zonation. Therefore, an intragenus phylogenetic framework of *Gnathodus* is needed.

Numerous *Gnathodus* specimens were recovered from South China carbonate sections, e.g., the Naqing section of Guizhou, the Yudong section of Yunnan, and the Yajiao section of Guangxi. By incorporating published data elsewhere, we compiled a detailed matrix of morphological characters of the genus *Gnathodus*. Additionally, information on two species of *Protognathodus* that was generally considered as the ancestor of *Gnathodus* were also included in this matrix. Followed by cladistic analysis using TNT and R, the phylogenetic relationship based on the P1 elements of all *Gnathodus* species/subspecies is reconstructed. Furthermore, the Dispersion-Vicariance Analysis is also applied in this work to profile the paleobiogeographic immigration and dynamic variations of *Gnathodus* during the Mississippian and Early Pennsylvanian. Our results reveal a temporal and spatial evolutionary model for the conodont genus *Gnathodus*, which provides a meaningful reference for the taxonomic and biostratigraphic application of the genus *Gnathodus*, as well as that of other related Carboniferous taxa. Future discoveries of multielement apparatuses will serve as a test and facilitate a comprehensive revision of the phylogenetic relationship of *Gnathodus* proposed in this work.

Farfield effects of the Hercynian orogeny on the sedimentary succession of the Arabian Plate

Michael H Stephenson[1]*, Stephenson Geoscience Consulting Ltd (mikepalyno@me.com)

Abstract

The Hercynian orogeny was a period of tectonism during the Carboniferous, due to collision of Gondwana and Laurasia forming Pangea, and causing severe tectonic and orogenic effects in western Europe, northwest Africa, and eastern North America. The farfield effects of the orogeny are however less well known. High precision palynological analysis across the entirety of the Arabian Plate has identified a sedimentary hiatus (the Hercynian unconformity), and faulting, associated with the Hercynian orogeny, which can be traced from Israel and Jordan in the north through western Iraq, Saudi Arabia, the Gulf States, and Oman, showing that the hiatus ranges from the Proterozoic to the Mid-Permian in the Levant, and Ordovician to Mid-Permian in northern Oman, to much smaller durations corresponding to part of the Carboniferous in the Nafud-Ma'aniya and Faydah-Jafurah basins. The form of the Hercynian unconformity is complicated by contemporaneous salt dissolution and withdrawal, and deposition on erosional features caused by the Permo-Carboniferous glaciation with which it is party co-eval. The Hercynian unconformity and associated faulting are the most important stratigraphic controls on the Palaeozoic of the Middle East, affecting the geographic and stratigraphic distribution of sedimentary rocks that have value for groundwater and carbon storage, as well as being oil and gas source and reservoir rocks. This palynological survey allows unique insights into the farfield 'ripples' of a major orogenic event, the origin and character of the unconformity, and the interplay between Palaeozoic tectonic and glacial controls on erosion and deposition.

Revision of Idiognathodus sagittalis (Conodonta, Pennsylvanian): 2D- and 3D-based morphometrics

Yingjun PENG[1]*, Nanjing University (211840284@smail.nju.edu.cn)
Keyi Hu[2], Nanjing University

Abstract

Conodonts are one of the major fossil groups for stratigraphic subdivision and correlation in the Paleozoic and Triassic. Conodonts Swadelina subexcelsa, Idiognathodus heckeli, I. turbatus and I. sagittalis have been proposed for the Global Moscovian-Kasimovian stage boundary. Among them, I. sagittalis was named earliest and plays a crucial role in recognizing the alternative Moscovian-Kasimovian boundary in the Russian Platform. The evolution pattern of I. swadei-I. heckeli-I. turbatus is better understood based on conodont data from North American Midcontinent and South China, while the ancestor and evolutionary pathway of I. sagittalis are poorly known. In the 3D morphology of P1 elements, I. sagittalis is primarily distinguished by its lobes that turn lower than the upper surface of other parts of the platform. Beyond that, elements of I. sagittalis reported from the Russian Platform and South China resemble those of I. swadei-I. heckeli-I. turbatus lineage in their 2D morphology as they share a wide rostral lobe shifting dorsally, longitudinal alignment of the rostral ridge, carina, and caudal ridge, and the flaring, high-elevation caudal adcarinal ridge. Here, 2D- and 3D-based morphometrics analyses are applied to distinguish I. sagittalis from the elements within the I. swadei-I. heckeli-I. turbatus lineage. In this study, we compile a dataset that includes conodonts I. sagittalis and other similar forms from South China and published data elsewhere followed by the Bi-lobed Landmark Analysis (BLA), Principal Component Analysis (PCA), and Canonical Variate Analysis (CVA) of 2D-based morphometrics analyses, and various 3D-based indexes (e.g., RFI, Slope). The PCA shows that I. sagittalis has several morphotypes that fit into the groups of I. heckeli or even I. swadei. In the CVA scatterplot, I. sagittalis, I. heckeli, and I. turbatus are separated well. However, the holotype of I. sagittalis is completely mixed with the I. turbatus cloud because of its highly similar morphology with I. turbatus, e.g., the medial nodosity. Additionally, topographic indices show that I. swadei, I. heckeli, I. turbatus, and I. sagittalis share a similar sloped rostral lobe angled from 20°-40°, distinguished from that of I. sulciferus and I. harkeyi angled from 0°-20°. Combining with 2D and 3D analyses, We conclude that 1) I. swadei, I. heckeli, I. turbatus, and I. sagittalis are a distinctive group differing from other Idiognathodus species; 2) the P1 element of typical I. sagittalis should be diagnosed by its medial nodosity and inclined rostral lobe angled 20°-40°, 3) I. heckeli has a complete eccentric groove and maybe the sloped rostral lobe; 4) the species name I. turbatus may not be valid due to that the I. sagittalis was named earlier and its holotype represents characteristics of I. turbatus; and 5) specimens referred as to I. sagittalis from Russian Platform and South China comprised of several morphotypes and need to be named as new species. This study offers a better understanding of the species concept of the conodont I. sagittalis. However, North American specimens, especially I. heckeli and I. turbatus, are better included for 3D

morphometrics analyses to verify the similarity between them and I. sagittalis.

Abstract

The late Paleozoic ice age (LPIA) is the only archive in the Phanerozoic that recorded the permanent icehouse-to-greenhouse turnover, with complex terrestrial ecosystems and metazoan life on the plant, which provides an ideal analog for the late Cenozoic glaciation. In recent decades, abundant studies supported that the LPIA was characterized by a pattern of a dynamic, multi-centered continental icesheets with discrete glacial intervals. Continental chemical weathering, regarded as a thermostat for the habitable plant in time scale of 10^5 years, plays an important role in the evolution processes of the late Paleozoic ice age. Chemical index of alteration (CIA) is widely used as a proxy for chemical weathering in literature, despite potentially underlying uncertainties. To date, CIA records have been published from both high-middle latitude and low latitude regions during the LPIA. However, there is generally lack of a long-term CIA record from low-latitude, continuous successions, which hampers our understanding of evolution of the paleoclimate during the LPIA. Here, we present major and trace element compositions for the argillaceous limestones and calcareous shale in the continuously deposited, Naqing succession (Carboniferous to early Permian), South China. Given that the South China Block was located around the palaeoequator in isolation, the CIA record of the Naqing section provides an important opportunity for investigating the interaction between glaciation and chemical weathering during the LPIA.

Abstract

Carbonate uranium isotopes (238U/235U, denoted as δ238Ucarb) are recently widely utilized to understand marine redox landscapes, but mostly focusing on quantitative estimation on the extent of seafloor anoxia, especially during major biotic crisis and ocean anoxic events of the Phanerozoic, which is often tied to global carbon cycle perturbations. More recently, limited δ238Ucarb data also documented repeated occurrences of marine anoxia during the deep glacial of the late Paleozoic icehouse. Nevertheless, the episodic nature and mechanism of the marine redox changes in response to global C cycling during the late Paleozoic icehouse, particularly under high atmospheric pO2 levels, remain unclear. Here we present a high-resolution time series of δ238Ucarb for a deeper-water, carbonate slope succession (Naqing, South China) spanning the Middle Pennsylvanian through to the early Permian (~310–290 Ma). Along with the high-resolution carbonate δ13C from the same succession, and multi-proxy-based atmospheric pCO2 estimates, we further explore the mechanisms of the late Paleozoic (de)oxygenation utilizing a refined, previously established CPU (carbon, phosphorus, and uranium) biogeochemical model. The modeling outcomes, integrated with proxy data, suggest a long-term atmosphere and seafloor oxygenation driven by enhanced marine organic carbon burial. The study also highlights that episodic pulses of C emission can cause repeated occurrences of marine anoxia even under more oxygenated Earth system than today.

Abstract

The Late Paleozoic Ice Age (LPIA) is one of the most significant glacial events during the Earth history, lasting for nearly 100 million years (360-260 Ma). It recorded the only complete transition from an "icehouse climate" to a "greenhouse climate" after the occurrence of advanced vegetation and complex ecosystems on land. This critical climate transition started in the Artinskian of the Early Permian (also known as the Artinskian Warming Event, AWE). Although the AWE was hypothesized to have been related to greenhouse gas emissions, its specific causative mechanisms remain unresolved. Widespread volcanic activities in the Early Permian were presumably considered to be an essential trigger for this warming event, but without direct evidence. Mercury (Hg) enrichment and isotopes have been widely used as a robust proxy for volcanic activities and paleoenvironmental perturbations in recent years. The combination of Hg enrichment and isotopes can effectively indicate volcanic activity and its association with climate events. This paper present high temporal resolution time series of Hg concentration and isotopes in three continuous outcrop sections and one drilling core from the South China, Junggar, Spitsberg, and North China blocks, in order to explore the potential driving mechanisms for the AWE, particularly its linkage with volcanic activities during the critical climate transition.

Abstract

The earliest Carboniferous saw a critical climate transition from the Devonian greenhouse to the late Paleozoic icehouse climate state, which is featured by a worldwide, mid-Tournaisian positive carbon isotope excursion (TICE). Regardless of uncertainties in single versus double peaks in carbonate carbon isotope record (δ13Ccarb), the TICE was thought to have caused by increased organic carbon burial, the underlying mechanism of which, however, remains controversial.

Zinc (Zn) is a vital micronutrient for organisms, and Zn isotopic compositions (δ66Zn) of seawater are mainly controlled by marine primary productivity and continental weathering, which are tightly connected to global carbon cycling. Thus, Zn isotope has the potential to disentangle the interlinked processes during the TICE event. Here, we present the first carbonate δ66Zn record, in combination with other geochemical data, from two well-preserved, carbonate dominated successions (Malanbian and Xiasi) from the northeastern Paleo-Tethys Ocean region (South China Block). During the TICE interval, the coupled δ66Zn and δ13C profile delineates two peaks, indicating that the TICE event is a two-phase carbon cycle perturbation. Both phases are attributed to enhanced marine primary productivity, which was stimulated by increased micronutrient supply from continental weathering and oxidation of previously buried organic matter, respectively. Consequently, the two-phase, enhanced productivity and the resultant organic matter burial could have led to a stepwise climatic cooling.

Volcanic activities, wildfires and the collapse of tropical rainforest ecosystems during the terrestrial end-Permian mass extinction in Southwest China

Hua ZHANG[1]*, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences (hzhang@nigpas.ac.cn)
Yaofeng Cai[2], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences
Shenglin Jiao[3], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Abstract

The end-Permian mass extinction (EPME) was the most severe extinction event in the last 500 million years, with estimated losses of >81% of marine and >89% of terrestrial species. The extreme Cu enrichments, Hg concentration spikes, presence of melt inclusions with rich Cu and sulfides within the EPME interval in South China derived from explosive super-eruptions near the South China Block during the closure of Paleo-Tethys or opening of Neotethys. Model estimates from the Community Earth System Model (CESM1) suggest such a massive SO2 release would lead to immediate post-eruptive atmospheric cooling of > 4 C on a thousand-year timescale (‘volcanic winter’) prior to the previously reported rapid global warming across the EPME. This temperature trend is consistent with a drastic sea-level fall at the onset of the EPME followed by an immediate transgression. Rapid cooling on top of longer-term warming increases the climatic extremes experienced by terrestrial ecosystems. This bolsters the case that environmental degradation due to rapid climate shifts was an important kill mechanism during the end-Permian biotic crisis. Abundant well-preserved charcoals with anatomical structures indicate the wildfires were widespread during the Permian–Triassic transition in Southwest China. Organic carbon isotopic analyses of both bulk rocks and charcoals show that the δ13Corg values in the Lower Triassic are notably more negative than those in the Upper Permian, with a negative excursion of 4.08‰ immediately above the volcanic ash bed in the middle of the uppermost coal bed of the Xuanwei Formation. The enrichment of polycyclic aromatic hydrocarbons (PAHs) in the terrestrial EPME interval in Southwest China indicates that the paleotropical rainforest ecosystem provided sufficient fuel for large-scale high-temperature wildfire combustion events. Furthermore, the extremely low PAH contents in the Lower Triassic showed a fuel shortage after the mass deforestation. These results suggest that intensified high-temperature wildfire combustion events in the paleotropical rainforest in Southwest China occurred because of global warming and aridity caused by intensive volcanic activities, and led to the eventual collapse of tropical rainforest ecosystems during the P–T transition.

Xiaoqi Fan[5], China University of Petroleum, Beijing
Siyu Zhou[6], China University of Petroleum, Beijing

Abstract

At the end of the Middle Permian Guadalupian sedimentation period, the Chinese region recorded the only internationally recognized large igneous provincial eruption event, known as the Emeishan LIP. The Yangzi region of South China records a series of short and almost synchronous geological events that accompanied the development of bio-geological events such as large-scale magmatic intrusion, plate rifting, magnetic pole anomalies, and ecological collapse. These events ultimately triggered the extinction of living organisms. However, the current study leaves several questions unanswered. What was the sequence of geological events? Are the global record of these events synchronized? What is the causal relationship between these events?

For this study, the research subject consisted of seven sections located on the northwestern margin of the Yangtze Plate, such as Sanduizheng, Wangjiagou, Daliangxiang, among others. The study determined the stratigraphic time limit based on lithological characteristics and conodonts, and discussed the sedimentary responses to various geological events using isotopic and astrochronological analysis.

The results reflect: 1Fossils from the Jinogondolella.postserrata zone have been discovered in several locations, including the 28th floor of Maoertang, the 33rd floor of Sanduizheng, the 28th floor of Longfengcun Village, and the 28th floor of Wangjiagou. These sections maintain an uninterrupted sedimentary recording of the Roadian-Wordian stage; 2During the late Wordian period, regional profiles document changes in depositional patterns and paleomorphic patterns; 3The Roadian-Wordian stage continued for a total of 8.2Ma. About 2 million years ago, roughly 19 cycles of 405Ks were established, whereas the sedimentation rate notably declined after the late Wordian period (267.8Ma). Significant negative carbon isotope biases were recorded in several profiles during the same period, indicating relative sea level fluctuations.

During the late Wordian period, Relative changes in depositional patterns and sea level under the combined control of Emei mantle column activity and Yangzi rifting. Above the J.postserrata zone, the magma emplacement due to Emei mantle plume became increasingly evident, and hydrothermal fluid gradually infiltrated the paleo-ocean after the J.altudaensis zone. We want to identify the initial triggers of various geological events by analyzing the sedimentary record.

Tipping cascades in the onset of the Carnian Pluvial Episode (Late Triassic)

Bo WANG[1]*, Nanjing Institute of Geology and Paleontology (bowang@nigpas.ac.cn)

Abstract

Exploring the onset of past hyperthermal events is essential to improve predictions on future climate change. The Late Triassic Carnian Pluvial Episode (CPE) is an interval with a dramatic increase in global humidity and temperature and profound biological turnover in marine and terrestrial ecosystems. However, its onset and drivers are still poorly understood. Here, we present an integrated high-resolution proxy from an Carnian lacustrine succession (Huangshanjie Formation in Dalongkou section) of the paleo-high-latitude Junggar Basin of northwestern China. Our U–Pb zircon dating, high-resolution chemostratigraphy and cyclostratigraphy, and palynological and sedimentological data reveal that a warm and drought climate in the region through the CPE, which is consistent with independent climate modeling evidence. Our results show that mercury concentrations increased about 45,000 years before the negative carbon-isotope excursion (CIE) but returned to normal level slightly prior to CIE. It suggests that the Wrangellia Large Igneous Province (W-LIP) is slightly earlier than CPE, may be not the major trigger of CPE. The CIE lasted about 32 kyrs and was most likely caused by the abrupt oceanic methane emissions triggered by the global warming and orbital pacing. Together, our results show that the crucial carbon perturbation and climate changes were triggered by tipping cascades of volcanism, orbital pacing, and oceanic methane emissions.

The state of the art on the redefinition of the Devonian/Carboniferous Boundary

Markus ARETZ[1]*, Université Paul Sabatier (markus.aretz@univ-tlse3.fr)
Carlo Corradini[2], University of Trieste

Abstract

The definition of the base of the Carboniferous has been back on the agendas of the Devonian and Carboniferous subcommissions for more than a decade. This became necessary after the discovery of the marker fossil for the base of the Carboniferous, the conodont Siphonodella sulcata, in a stratigraphical lower position in the GSSP section at La Serre, southern France. A joined SDS/ISCS Task group has been working on the redefinition of the base of the Carboniferous for more than ten years. Its overall aim is to regain stratigraphical stability in this critical interval of Earth history without fundamentally changing the position of the DCB in respect to previously used levels for the base of the Carboniferous.

The working group has been following the basic idea that a newly defined boundary level has to ensure the best possible correlation across facies realms and palaeocontinents, and that the recognition of the boundary should be the most user-friendly. In this respect, the new boundary should not depend on a single criterion, but be based on a suite of multiple criteria.

Hence, the working group has been focused on multi-disciplinary approaches, which combine palaeontological, sedimentological, geochemical and petrophysical methods and data, setting points in time during the latest Devonian and earliest Carboniferous.

The working group proposes to place the boundary at a point in time defined by “the end of the Devonian mass extinction and beginning of the Carboniferous radiation, the top of a major regression, and the base of the Protognathodus kockeli conodont Zone” and this level is inserted in a calendar of a succession of widely recognizable points in time for the latest Famennian and earliest Carboniferous. Since this DCB calendar combines results from very different facies realms, it is self-understanding that a section comprising all listed points will not exist. However, the application of this calendar enables to place every section as precise as possible into the framework of the DCB. Additionally, it clearly helps to identify local or regional variations and discrepancies due to e.g. facies differences or faunal particularities, and hence to adapt the position of the boundary accordingly. Thus, even a delayed entry of a stratigraphic marker would have less influence on the boundary position and the global correlation. The work on the calendar also implies revisions on existing biostratigraphic zonal schemes.

Chaotic Mars-Earth swings in precession of orbital perihelion revealed in Jurassic lake sequences, Junggar Basin, northwestern China

Yanan Fang[1]*, Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences (ynfang@nigpas.ac.cn)
Paul Eric Olsen[2], Columbia University
Bo Wang [3], Nanjing Institute of Geology and Palaeontology, Chinese Academy of Sciences

Abstract

A fundamental problem in celestial mechanics is Solar System chaos, with the fundamental secular frequencies of the rocky planets being unpredictable after 60 Myr. Especially sensitive, is the grand eccentricity beat cycle of Mars and Earth that potentially ranges in period over a million years on times scales of 10s of millions of years and modulates the expression of higher frequency axial precession cycles. Based on stable carbon isotopic and sedimentary facies data from the lacustrine, paleo-high-latitude Early Jurassic Sangonghe Formation of the Junggar Basin (NW China), and data from eastern North America, Japan, and Europe, we posit a dramatic oscillation in period of the Mars-Earth cycle from ~1.8 Myr to ~2.5 Myr back to ~1.6 Myr from 210 to 180 Ma, spanning nearly the entire range of plausible variation due to chaotic diffusion during the last 300 Myr.

Sangonghe Formation strata were deposited under warmer and drier conditions compared to bracketing Late Triassic to earlier Jurassic and early Middle Jurassic formations, based on the absence of ice-rafted debris, rarity of coals, presence of red beds, and higher percentages of the conifer pollen Classopollis, with the Jenkyns (T-OAE) event embracing one of the ~1.6 Myr cycle and marking an even warmer interlude. As these events unfolded within the context of hypothesized true polar wander dramatically effecting Junggar Basin latitude, deciphering the role of possible true polar wander vs. true climate change will require new palaeomagnetic and geochronological data from core spanning much of the Junggar Basin Mesozoic.

Carbon isotope perturbations driven by volcanism during the Late Paleozoic Ice Age (LPIA)?

Zhihui ZHANG[1]*, Shandong University of Science and Technology (zhzhihui@sdust.edu.cn)
Luojing WANG[2], Shandong University of Science and Technology
Dawei LV[3], Shandong University of Science and Technology

Abstract

Volcanic activity is considered to be one of the crucial underlying mechanisms driving extreme climate warming events in Earth's history. The late Paleozoic ice age (LPIA) was the longest-lived glaciation of the Phanerozoic, and the demise of LPIA is the Earth's only recorded transition from an icehouse to a greenhouse state. Many previous studies attributed climatic and environmental changes during the LPIA to perturbations of atmospheric pCO2, which also believe volcanism is an important driving mechanism for the warming events. However, the low-resolution carbon isotope and volcanic records during the LPIA in the North China Craton (NCC) limit the construction of a Permo-Carboniferous chemostratigraphic framework and global or local stratigraphic correlation, thus constraining the accurate understanding of volcanic activity for climate change. To investigate these issues, we analyzed high-resolution Hg concentration, total organic carbon (TOC), total sulfide (TS), and organic carbon isotope (δ13Corg) during the late Gzhelian to early Kungurian stages in the NCC, and compared the δ13Corg data with published records to build a chemostratigraphic scheme and discuss the potential climate change. The records show two global δ13Corg negative excursions which coincide with the shift in atmospheric pCO2, change of conodont oxygen isotope (δ18O), sea-level variation, and late Paleozoic deglaciation records, suggesting the presence of the global warming event in the late Gzhelian and the early Asselian. The high resolution of Hg/TOC recorded two volcanic activities, but the absence of synchronous correspondence between the δ13Corg negative excursions and Hg/TOC peaks hinted at a limited driving role of volcanism in the perturbations of carbon isotope and the change of paleoclimate in this study. It is worth noting that the onset of the early Asselian warming event coincides with the peak in volcanic intensity, which indicates that the early Asselian warming event can be attributed to volcanism with the superimposition of multiple mechanisms such as tundra conditions, methane release, or orbitally-paced climate changes. Our investigation provides a significant view that the decoupling relationship between the perturbations in the carbon cycle and volcanic activity during the LPIA. The perspective extends our understanding beyond volcanism resulting in climate change, revealing the potential multifaceted driving mechanisms behind the carbon cycle and climate change during the LPIA.

Abstract

Calibrate detailed ammonoid and conodont biostratigraphic data and carbon isotopic excursions around the Smithian–Spathian boundary is reported in the Phukhaothong Dolomite Member of the marine Triassic Chaiburi Formation (part of the Sibumasu [or Shan-Thai] Block), which is exposed on the north side of an isolated mountain at Khao Thong in the Phatthalung area of southern Thailand. The 104 m+ thick section, consisting of bedded to massive, light grey dolomite, contains ammonoids in the middle to upper parts, and conodonts occur in abundant throughout the section. Two distinct lower Spathian (upper Olenekian) ammonoid zones, an upper Smithian (lower Olenekian) conodont zone and three lower Spathian conodont zones are recognized in ascending order as follows: ammonoids - Tirolites–Columbites Zone and Idahocolumbites Zone; conodonts - upper Smithian, Hadrodontina aequabilis–Staeschegnathus perrii Zone, lower Spathian Icriospathodus crassatus Zone, Triassospathodus symmetricus–Novispathodus anhuiensis Zone and Novispathodus sp. I – Novispathodus sp. J Zone. The positive excursion in δ13Ccarb with values increasing from – 0.97‰ to + 3.86‰ was recorded in the upper Smithian, Hadrodontina aequabilis-Staeschegnathus perrii Zone. The δ13Ccarb values gradually decrease in the lower Spathian Icriospathodus crassatus Zone. These δ13Ccarb isotopic patterns are correlated with well-known positive excursions around the Smithian – Spathian boundary grobally.

[Keynote] Astrobiological significance of Stromatolites and organic walled microfossils on early Earth : Evidence from Lesser Himalayan Proterozoic stromatolitic cherty carbonates of India

VINOD CHANDRA TEWARI[1]*, Professor of Geology (Retd.), Sikkim University, Gangtok – 737102, Sikkim, India (Professorvct54@gmail.com)

Abstract

Astrobiology is the study of the origin, evolution, distribution, and future of life in the universe. This multidisciplinary field encompasses the origins, early evolution of life ,its diversification and extinction on Earth. Astrobiology studies includes the fundamental questions like how does life begin and evolve? Is there evidence of fossilized life preserved beyond Earth in the universe and, if so, how can we detect it? What is the future of life on Earth and in the universe?.Astrobiological research with other geological and planetary sciences. on Mars, Europa (Jupiter's moon),Titan and other planets in our Solar System is already included in the space bound Astrobiology Program of leading space agencies like NASA,ESA, ISRO,ASA, and Universities of UCLA,USA,Auckland and Australia in particular to name a few. Northwestern and Sikkim –Arunachal eastern Lesser Himalaya in India , Nepal and Bhutan is geologically and paleobiologically an important area in the South Asian Himalayan Orogenic belt to understand the Astrobiological paleobio events in the earth's history. The Meso-Neoproterozoic shallow marine stromatolitic carbonate sedimentary facies (Buxa Dolomite) in South Sikkim and Siang window, Arunachal Himalaya have yielded Pre –Ediacaran organic walled microfossils and stromatolites predating the Neoproterozoic (Snow Ball Earth) glacial event of global significance in the Sikkim-Arunachal Himalaya.In the Northwestern Himalaya from Jammu to Uttarakhand identical Pre –Ediacaran microfossil and stromatolitic assemblage is recorded from Jammu Limestone, Shali Limestone ,Deoban- Gangolihat Dolomite.Highly diversified assemblage of stromatolite taxa Colonnella columnaris, Conophyton garganicus, Kussiella kussiensis, Baicalia sp., Jurusania sp., Minjaria sp., Gymnosolen sp., Kalpanaella sp., Stratifera sp., Colleniella sp., Tungussia sp., Nucliella sp. and Acaciella sp., are developed in the inner South Asian Lesser Himalayan belt.The chert bands associated with the stromatolites have yielded organic walled microfossils Siphonophycus sp., Eomycetopsis sp., Obruchevella sp., Myxococcoides sp. and Oscillatoriopsis sp.The Laser Raman Spectroscopy and Confocal Laser Scanning Microscopy have shown that these cyanobacteria are biogenic and can be considered proxies for the extraterrestrial life on other planets.Recently, some Astrobiologists from NASA have compared the possible images of stromatolites, microbial mats, mud cracks ,magnetic bacteria like features found in iron deposits on the craters of Martian surface. Perseverance is collecting Martian samples to be studied on Earth in near future on Mars sample return to Earth which will inform about Martian paleoenvironment.The association of phosphorite, magnesite, iron and suphide mineralization with stromatolites indicate biomieralization in Meso-Neoproterozoic microbial carbonates of the South Asian Himalayan belt.

Abstract

Changes in global sea level and surface temperature are critical to changes in biodiversity, but how they affect biodiversity change is unclear. In this study, we reconstruct the trajectory of late Permian sea level change and compare it with the trajectory of δ13C and δ18O (a surface temperature proxy) values and the trajectory of species numbers. We fund that sea levels and temperature change synchronously and inversely under a greenhouse climate, Their impacting on organisms are consistent. Rising sea levels and decreasing sea surface temperature improve the ecosystem and, conversely, lead to ecosystem deterioration. The upper limit of optimum temperature for benthic organisms is ~22.6 °C; if the temperature beyond ~28 °C, their ecosystems will begin to collapse. However, the benthic effects of these two temperature thresholds are primarily achieved by enhancing or eliminating oxygen-rich underflows (thermohaline cycling), where the former enriches the underlying water with oxygen and nutrients, whereas the latter deoxidises it. In addition, the sudden warming at the beginning of the end-Permian extinction was not a periodic change in surface temperature but an anomalous change that have been caused by sudden events, such as the increase in atmospheric pCO2 and the paleogeomorphic change caused by plate collision.

Did CO2 emissions from the Siberian Traps volcanism outpace silicate weathering following the end-Permian mass extinction?

Ying cuiy@montclair.edu CUI[1]*, Montclair State University (cuiying00@gmail.com)

Noah Planavsky[7], Yale University

Abstract

The end-Permian mass extinction (EPME) event is thought to be caused by significant CO2 emissions from the Siberian Traps volcanic activity. Previous studies have shown that thermogenic CO2 emissions predates volcanic CO2 outgassing, leading to strong ocean acidification, large-scale deoxygenation, and loss of marine species. Following the EPME, CO2 outgassing persisted and caused extreme greenhouse condition in the earliest Triassic. Silicate weathering rate following the large CO2 pulses from the Siberian Traps volcanism, however, has not been quantified. As a result, the idea that CO2 emissions from the Siberian Traps volcanism exceeded the rate of silicate weathering remains untested. Here, we quantify the CO2 emissions and silicate weathering using carbon and lithium isotopes (δ13C and δ7Li), and other weathering-sensitive proxies (e.g., 187/188Os and 87/86Sr) as tracers of silicate weathering combining data assimilation in an Earth system model of intermediate complexity. Proxy records suggest that chemical weathering flux remains low, while physical erosion rates are elevated, indicating the earliest Triassic warmth may be attributed to continued CO2 outgassing from the ST volcanism and contributions from reverse weathering. The low chemical weathering flux was likely attributed to the hot and dry climate in the continental interior during high continentality, as supported by climate model simulations.

Stratigraphic position of various stromatolitic successions in Nepal Lesser Himalaya

Megh Raj DHITAL[1]*, Tri-Chandra Multiple Campus, Tribhuvan University (mrdhital@gmail.com)

Abstract

Stromatolites occur in a few Proterozoic Lesser Himalayan sedimentary sequences of the Nepal Lesser Himalaya. Such successions are frequently considered to be of the same age. However, detailed field mapping as well as stratigraphic and sedimentological investigations demonstrate that such correlation based on stromatolite occurrence alone is untenable.

In west Nepal, Fuchs and Frank (1970) identified the Shali and Krol Formations containing stromatolites. Bashyal (1982, 1986), and Shrestha et al. (1985) mapped stromatolite-bearing units of Far-West Nepal as the Baitadi Carbonates and Lakharpata Formation respectively. In central Nepal, Stöcklin (1980) identified the Dhading dolomite with stromatolites. On the other hand, Sakai (1983, 1986) mapped stromatolitic horizons in the Chappani, Khoraidi, and Kerabari Formations from the outer Lesser Himalayan zone of central and west Nepal. Dhital and Kizaki (1987) mapped a similar rock succession from west Nepal of the Dang-Sallyan area, where the stromatolites occur in the Hapurkot, Dhorbang Khola, and Ranibas Formations. In the Lesser Himalayan zone of the Syangja area in west Nepal, Dhital et al. (2002) identified the stromatolitic Ripa Member in the Sorek Formation. In eastern Nepal, stromatolites also occur in the Halesi Dolomite (Dhital 2006).

Scrutiny of such successions demonstrates that there are at least four separate stromatolite-bearing horizons of Meso- to Neo-Proterozoic age. The lowest one is the Dhading Dolomite, Shali Formation, Baitadi Carbonates, or the Lakharpata Formation. The Sorek Formation and Halesi Dolomite occur in an intermediate position, whereas the Chappani-Khoraidi or Hapurkot-Dhorbang Khola Formations occur in the upper part. On the other hand, the Krol, Kerabari, or Ranibas Formations occupy the topmost position in the Proterozoic stratigraphic rung.

End-Permian continental vegetation collapse directly affected marine ecosystems; Evidence from Permian-Triassic successions of Australia.

Vivi Vajda[1]*, Swedish Museum of Natural History (vivi.vajda@nrm.se)
Kliti GRICE[2], Curtin University

Abstract

The end-Permian mass extinction event led to major devastation in continental ecosystems with disappearance of forests, wild fires, desolated land, and toxic lake systems. Anoxic conditions triggered widespread marine extinctions, profoundly impacting various oceanic taxa. However, links between terrestrial and marine environments are lacking.

Here we demonstrate, based on palynological analyses of Permian-Triassic successions of Western Australia, Perth Basin, that the mass kill of Permian vegetation had an immediate impact on the marine faunas. Massive buildup of organic matter lead to extensive algal blooms mirrored in the overwhelming abundance of green algae (acritarchs) leading to euxinia in the photic zone (Vajda et al. 2023a,b). This dead zone is in Eastern Australia dated to 252.10 ± 0.06 Ma. We show, through X-ray absorption spectroscopy, that a drastic redox shift across took place across the extinction interval with increasing amount of reduced Fe-species followed by highly oxidized Fe-species, most resembling Fe(III) complexed with organic matter. The highly reduced iron in the extinction layer may relate to methane release from bacterial degradation, or emissions from clathrates. The presence of fulvic acid in the distinct iron-rich extinction layer indicates that an abrupt onset of the process of degradation of plant matter, lipids and calcium hydroxide (CaOH) took place, resulting in this ‘Death layer’.

The anoxia ultimately pushed the marine faunas to an ecological extinction. The last lingering occurrence of marine invertebrates of Permian aspect occur in layers that mark the Permian–Triassic boundary, positioned just below the appearance of Triassic floras and the pioneer faunas with high abundance of the bivalve Claraia. This phenomenon allows for correlation with the emergence of post-extinction pioneer floras in the Early Triassic of eastern Australia. Our findings highlight a substantial temporal gap between the recovery of terrestrial and marine pioneer biota in high-latitude Gondwana, with a significant delay observed in faunal recovery.

Stable sulfur isotope dynamics of reduced inorganic and organic sulfur phases recorded in the Permian-Triassic transition of the Meishan type section

Paul Francis Greenwood[1]*, Curtin Univeristy (p.greenwood@curtin.edu.au)
Hendrik GROTHEER[2], Alfred Wegener Institute for Polar and Marine Research
Michael E. E. BÖTTCHER[3], Leibniz Institute for Baltic Sea Research , Germany
Kliti GRICE[4], Curtin University

Abstract

Sulfur cycle fluxes of the Permian-Triassic mass extinction traditionally studied by the sulfur phase abundances in sedimentary rocks and the stable sulfur isotopic value (34S) of mineral sulfates may be complemented by studies of reduced and organic sulfur. The 34S and concentration analyses of total reduced inorganic sulfur (TRIS), kerogen (Ker) and individual organosulfur compounds (OSCs) has been conducted on sediments across the Late Permian to Early Triassic marine type section of Meishan-1 (South China). The relatively steady 34S profiles of all sulfur phases measured through the late Permian were indicative of a primary seawater sulfate control, but other biogeochemical modulators caused prominent 34S fluctuations of TRIS and OSCs adjacent to the extinction event. The late Triassic 34STRIS profile of Meishan-1 displayed a notable enrichment (+15 ‰) concomitant with a depletion in 34SOSC (-7 ‰), whereas co-eval 34SKerS values remained relatively constant. The contrasting 34SOSC and 34SKerS data suggests the dynamic behavior of specific diagenetic sulfurisation processes may be resolved by the 34S of discrete OSCs, but dissipated in the bulk kerogen fraction. The inverse isotopic trend observed between OSCs and TRIS resulted in negative 34SOSC-TRIS values identifying organic sulfurisation with an unusual preference over pyrite (FeS2) for the lighter 32S. A redox control of the 34SOSCs and 34STRIS deviations in the extinction interval was confirmed by coincident variation in TRIS/(TRIS+KerS) and FePy/FeHR ratios. Fe speciation profiles indicated a transition to ferruginous conditions (i.e., ample Fe2+) in which the 34S depletion of OSCs promoted by the ferruginous setting may arise from the rapid and irreversible reaction of organic substrates with labile sulfur anions (e.g. HS-) or be supported by an especially localised sediment-water depositional microenvironment.

Abstract

The largest mass extinction 'event' of life (end-Permian) occurred when atmospheric O2 levels were low & CO2 & H2S rising. In contrast to the meteor induced end-Cretaceous extinction event that wiped out non-avian dinosaurs, climate forces of the end-Permian event came from the aggregation of Pangea & its volcanism. Green sulfur bacteria (GSB) were globally plentiful in the Late Permian seas implying abundant H2S, used by GSB in photosynthesis. Similar conditions have been invoked during all past global warming & biotic crises. However, recent molecular data showed conflated global C cycle disruptions for the end-Triassic extinction were related to an abrupt drop in relative sea level, & transition from marine to non-marine conditions with an emergence of microbial mats (MMs). The existence of MMs in the 'extinction zone' of the Chicxulub asteroid crater show that photosynthesis in the seas recovered within 200 kyrs. Detection of perylene (a fungal wood biomarker) in the crater tracked tsunami which flooded the crater within days after the impact - the first molecular days to week's resolution of a tsunami.

Some exceptionally preserved fossils inside concretions record preservation of soft tissues or articulated skeletal remains. This unique preservation of biomass is likely due to sequestration, & protection from degradation by e.g. MMs, for tens to hundreds of Ma by a rapid (days) microbial-induced carbonate deposition within days to months. Fossil concretions are a previously untapped biochemical record - providing many unique insights: e.g. diet; role of MMs in fossilisation; & the unique chemical pathways of natural products into biomarkers. During this presentation, examples of different modes of preservation (oxidation versus reduction) of biomarkers (biomolecules) & soft tissue from a range of fossils will be presented with examples from e.g. Devonian Gogo Formation (Canning Basin), Carboniferous Mazon Creek (Illinois, USA), Cretaceous Winton Formation (Queensland), Eocene Green River Formation (US), Jurassic Posidonia shale (Germany) & Devonian Rhynie chert (Scotland).

[Keynote] The end-Permian mass extinction: Progress and unexplained questions

Shuzhong SHEN[1]*, Nanjing University (szshen@nju.edu.cn)

Abstract

The end-Permian mass extinction (EPME) was the most severe extinction event in the past 500 million years, with estimated losses of >81% of marine and ~89% of terrestrial species. Past scenarios overwhelmingly suggested that the Siberian Traps large igneous province (STLIP) released a massive amount of greenhouse and poisonous gases (e.g., CO2 and SO2), leading to rapid warming, perturbing global carbon, and sulfur cycles, causing expanded anoxic/euxinic zones in the oceans and climate drought on land. Although the STLIP scenario has been widely accepted, temporal links between the EPME and volcanism were actually established based on sedimentary records from South China, specifically, the high-precision ID-TIMS U-Pb dates from two volcanic ash beds (beds 25 and 28) at the Meishan section in southeastern China. The Permian-Triassic boundary interval in South China is associated with multiple isotope anomalies likely linked to volcanic eruptions, and these anomalies have been mostly used to argue for a causal link between the EPME and STLIP. However, geochronological studies suggest the STLIP started ~300 ka before the EPME interval and persisted for 500 ka after the extinction. This is in contrast to the main extinction occurring within an interval of 31 ± 31 ka or less based on the sections in South China. Recently, more and more studies indicate that large scale felsic volcanic eruptions within the Palaeotethys Ocean, eastern Australia, South America were synchronous with the EPME, suggesting that the STLIP may not have been the sole trigger. In contrast to the rapid and contemporaneous marine EPME, high-precision CA-ID-TIMS zircon U-Pb geochronology from the global terrestrial ecosystem suggest that the terrestrial EPME extinction occurred diachronously with latitude, beginning at high latitudes during the late Changhsingian and progressing to the tropics by the early Triassic. Thus, the EPME resulted from both basaltic and felsic volcanisms is probably much more complicated than those documented before.

Vapour pressure deficit, drought, flood, fires, and CO2 spikes during the Permian-Triassic life mass extinction

Gregory John RETALLACK[1]*, University of Oregon (gregr@uoregon.edu)

Abstract

Floods, fires, and drought are increasing with current rise of anthropogenic CO2, and interrelationships between such disparate phenomena can now be tested from CO2 spikes of the geological past. This study examines the atmospheric CO2 spikes across the Permian Triassic boundary in South Africa from the new perspective of a paleosol proxy from the slope of oxygen and carbon isotopic correlation in carbonate for vapour pressure deficit (VPD), the drying power of air. Stable isotopic and major element data can be used as proxies for palaeotemperature. Past CO2 spikes can be quantified from carbon and oxygen isotopic data of pedogenic carbonate, with results similar to those from stomatal index of fossil leaves. Precipitation and its seasonality, can also be assessed from paleosols. Environmental disruption at the exceptional CO2 greenhouse spike during the Permian-Triassic transition in South Africa showed simultaneous spikes of VPD, precipitation, temperature, and flood. Unusually high VPD can also be seen in a compilation of stable isotopic data from calcareous paleosols at other CO2 spikes of the past, such as the Late Ordovician (Hirnantian, 446 Ma) and Late Devonian (Frasnian-Famennian, 374 Ma). High VPD, flood, fire, and drought recurred at times of high atmospheric CO2, and may have common cause in curtailed global stomatal conductance by plants, then transpiration termination by mass extinction itself.

Proterozoic stromatolite-bearing host rocks for nickel and cobalt mineralization in western Nepal

Sunil LAMSAL[1]*, Tribhuvan University (geosunil91@gmail.com)
Kabi Raj Paudyal[2], Tribhuvan University, Nepal
Vinod Chandra Tewari[3], Sikkim University, India

Abstract

Nickel and Cobalt are strategic minerals and have diverse uses with limited known deposits. Globally, Ni-Co-sulfide deposits are known from Paleoproterozoic to Neoproterozoic and Paleozoic Period. In the Asian region, this mineralization mainly occurred in the early Neoproterozoic rock successions. In Nepal Lesser Himalaya, nickel and cobalt are reported from three places. Nickel ore associated with copper mineralization is reported from the Nangre area in the Ramechhap district. Similarly, cobalt-copper mineralization in the Tamghas-Samarbhomar area from western Nepal and nickel-cobalt-copper association at Bauli Gad (Bajhang) from far western Nepal. Among this area, the present study is focused on mineralization along the Tamghas-Samarbhamar area to determine the depositional environment of the host rock, present status, and geological controls of mineralization. The present presentation is a part of the Ph. D research project of the first presenting author. Detailed geological mapping is conducted on a scale of 1:25000 with systematic samplings for both detailed petrographic studies and geochemical analysis. The host rock for the Ni and Co mineralization in Nepal Lesser Himalaya is the Proterozoic stratified and algal mat carbonate lithological unit in investigation. These carbonate rocks are considered equivalent to the Malekhu Limestone of central Nepal. Both types of mineralization: syngenetic as well as epigenetic sulfide mineralization are reported from the field observations in the present study. Nickel and cobalt in the area are associated with pyrite, chalcopyrite, lead, and zinc belonging to a polymetallic deposit. The AAS analysis of the sample gives the presence of nickel within 0.04 to 0.3 percentage and cobalt within 0.07 to 0.5 percentage. The detailed study of both Ni and Co ores and associated sulfide ores under ore microscopy reveals that there is a strong link between the mineralization and host rock Proterozoic stromatolites carbonate. Based on the types of stratified stromatolites preserved in these host carbonate rocks; the depositional environment of sulphide-bearing mineralization is interpreted as a shallow marine. In the present preliminary study, we have delineated the petrographic characteristics of host rock and sulfides of the nickel-cobalt-sulfide deposits. The detailed geochemical analysis and field relation of mineralization will provide information about the original ore-forming processes and the origin of Ni-Co-sulfide mineralization in Nepal Himalaya. Further findings are under investigation.

Identification and Significance of the Permian Guadalupian-Lopingian boundary in the northwestern margin of the Yangtze Craton

Xiaoqi FAN[1]*, China University of Petroleum (Beijing) (17863902533@163.com)
Fujie Jiang[2], China University of Petroleum (Beijing)
Di Chen[3], China University of Petroleum (Beijing)
Xuanwei Liu[4], China University of Petroleum (Beijing)

Abstract

The Guadalupian-Lopingian boundary (PLB boundary) of the Middle-Late Permian has long been a challenging issue in geoscience research. Tectonic uplift during the Middle-Late Permian transition resulted in sedimentary discontinuities and differential erosion, posing difficulties in defining the boundary and correlating it with global sections. In addition, multiple sections records negative carbon isotope excursion related to the PLB boundary, but with varying occurrence times, the cause of which remains unclear. In this study, we selected seven sections including Sandui Town, Wangjiagou, and Daliang Township in the late Guadalupian formations of the northwestern margin of the Yangtze Craton as the research objects. The stratigraphic ages were determined based on lithological characteristics and conodonts. Additionally, we supplemented the regional carbon isotope drift event with environmental evidence through the use of major, trace and rare earth element analysis methods, while also examining its relationship with geological events. The results show that: Firstly, from the Jinogondolella.postserrata to Clarkina.dukouensis zones, four lithologic intervals including bioclastic limestone (dolomitic limestone), siliceous rocks (argillaceous limestone), coal seams, and marl-bearing limestone were identified, representing three stages of sea-level stability, regression, and transgression. Then, based on palaeo-exposure surfaces, lithologic mutation surfaces, and the first occurrence of C.dukouensis conodonts, the position of the PLB boundary was identified. Subsequently, the J.postserra-J.shannoni zone and J.altudaensis-J.xuanhanensis zone in the Sandui Town section recorded two regression events, resulting in synchronous negative excursions of Sr/Ba and Y/Ho values, indicating relative enrichment of light rare earth elements. Finally, the Emeishan large igneous province became active at the J.altudaensis zone, with the input of hydrothermal fluids causing a sudden increase in the regional total rare earth element content. The biological populations were affected by an extinction event starting at the J.postserrata zone, which continued until the PLB boundary. In conclusion, this study complements the profile evidence by explaining the differences in the timing and period of negative carbon isotope excursion events between the northwestern margin of the Yangtze Craton and the global records.

Study of Meso-Neoproterozoic stromatolites and algal structures from the Lesser Himalayan carbonates of Nepal and their depositional environment

Basanta DEVKOTA[1]*, Tribhuvan University (basantadevkota012@gmail.com)
Lalu Prasad Paudel[2], Tribhuvan University, Nepal
Vinod Chandra Tewari[3], Sikkim University, India
Kabi Raj Paudyal[4], Tribhuvan University, Nepal

Abstract

In the present study, two major stratigraphic successions in the central and western parts of Nepal were traversed for the identification of stromatolites and other algal structures. These carbonate successions belong to the autochthonous units of the Nepal Lesser Himalaya. The exposed stromatolites containing carbonate formations were studied along the two road sections in the Kali-Gandaki River valley (Butwal-Tansen-Pokhara section) in western Nepal and the Malekhu area in central Nepal. Diverse stromatolites and algal structures are developed in the Dhading Dolomite unit of the Nawakot Group in central Nepal and the Chappani, Khoraidi, and Saidi Khola units of the Kali Gandaki Supergroup. Our focus was on understanding the microbial mat formation, growth of stromatolitic columns, and morphological variations ranging from simple stratiform to domal and columnar nonbranching to branching modes of occurrence. We also investigated various sedimentary and microbial carbonate facies, along with primary structures such as cherty bands and lenses, cross laminations, intraclasts, and oolites. We interpreted the paleoenvironment of deposition based on stromatolitic-algal growth, the shape of columns, and primary structures. We compared the growth pattern of the stromatolites from the Lesser Himalayas of Nepal with modern stromatolite development in Shark Bay, Australia, and Bahama, USA. The observed variation in stromatolite forms found in the carbonate successions of Nepal included crenulated mats, stratified and large domal, columnar (Colonnella columnaris), conical (Conophyton, possibly new form), and Kussiella kussiensis. These large stromatolitic columnar and conical forms were globally distributed and have been recorded from Pre-Ediacaran (Meso-Neoproterozoic pre-glacial) Lesser Himalayan carbonate formations of India (Gangolihat, Deoban, and Buxa Dolomite). These large stromatolites, domal algal structures and oolitic-intraclastic grains suggest a shallow marine tidal flat environment of deposition for carbonate rocks. Additionally, an attempt is made to understand the significance of stromatolites in the regional correlation of Lesser Himalayan stromatolitic carbonate sedimentary belts between Nepal and India during the Meso-Neoproterozoic (Pre–Ediacaran) time to understand the geological history of the South Asian region.

Study of the Late Permian radiolarian fauna from the Heshan Formation in Laibin, Central Guangxi Province

XiaoXin Dong[1]*, GuiLin Univercity of Technology (2515222377@qq.com)
QiangFen Ma[2], Guilin University of Technology

Abstract

The study of radiolarian fossils is a good way to study the Late Paleozoic deep-sea sediments. During the Late Permian, relatively complete marine strata were deposited in the Central Guangxi, this paper selected the well-exposed Chengxiang section and Siguan section in the Upper Permian Heshan Formation from the Central Guangxi. We found a large number of radiolarian fossils in the study sections, the overall morphology of radiolarians is mostly spherical and ellipsoidal, the shell has no main sting. By detailed appraisal of the radiolarians fossils, 8 species belonging to 8 genera had been identified, including the albaillellids, the spherical polycystine and the stauraxon polycystine: *Pseudoalbaillella globosa*, *Hegleria mammilla*, *Paracopicyntra ziyunensis*, *Entactinosphaera sp.*, *Cenosphaera sp.*, *Archaeospongoprunum chiangdaoensis*, *Somphoentactinia saecularis*, *Quadricaulis femoris*. By comparing the previous research data, it is found that most of the fossils in the study area are small in size, and the radiolarian genera and species have a significant decrease in radiolaria found in South China at the late Permian compared with the heyday, which is consistent with the characteristics of most extinction events in the Late Permian, and also confirms the research conclusions of the Permian mass extinction, and provides a basis for the study of the evolution of the late Permian radiolarian fauna.

Calcification of cell membranes: From ions to minerals

XIAO GAO[1]*, Shandong University of Science and Technology (xiaogao92@sdust.edu.cn)
ZUOZHEN HAN[2], Shandong University of Science and Technology

Abstract

Calcified microorganisms are a typical product of biomineralization. In this study, the whole process of cell membrane calcification of Bacillus licheniformis DB1-9 was studied by molecular dynamics (MD) and microbially-induced carbonate precipitation (MICP) laboratory experiments. Typical metabolitic products of Bacillus licheniformis DB1-9 were used as the calcium carbonate nucleation template to establish the organic constituents and a water-calcium carbonate two-phase system model for MD simulation, and to characterize the early stages of calcium carbonate nucleation on the surfaces of extracellular polymeric substances (EPS). The surface minerals of calcified bacteria obtained by MICP were prepared by focused ion-beam (FIB) and further analyzed using high-resolution transmission electron microscopy-selected area electron diffraction (HRTEM-SAED). We propose that the evolution process of cell membrane calcification is: ions → ion-pairs → multi-ion complexes (MIC) of large-size topological structures → pre-nucleated clusters (PNC) → amorphous calcium carbonate (ACC) → carbonate minerals (monohydrocalcite, vaterite, aragonite). In addition, ACC and the state before ACC were adsorbed on to the surface of the cell membrane after self-assembly in the aqueous solution; the ACC then underwent maturation and crystallized into ordered carbonate minerals with a crystal structure. Our study reveals the processes of microbial calcification, which has implications for the calcification of microorganisms in modern aqueous environments and for the formation of microbialites throughout the geological record.

The Złatne/Pieniny Basin as a part of the Alpine Tethys in Central and Eastern Europe

Jan Golonka[1]*, AGH University of Kraków (jgolonka@agh.edu.pl)
Anna Waśkowska[2], AGH University of Kraków
Michał Krobicki[3], AGH University of Kraków

Abstract

The Calcareous Alps and Central Carpathians formed the marginal platform of Western and Central Europe during the Triassic time. The Mesozoic rifting events caused the origin of oceanic type basins along the northern margin of the Paleotethys. The Pangean breakup resulted in the formation of the Alpine Tethys during Sinemurian/Pliensbachian time. This Alpine Tethys separated Eurasia (North European Platform and the Central Carpathian Plate). It was divided into the Złatne/Pieniny and Magura Basin separated by the Czorsztyn Ridge (intraoceanic submarine swell). The deeper water sediments, like radiolarites, were deposited in this basins, while shallower water carbonate sedimentation prevailed on slope of the Czorsztyn Ridge.

The Złatne/Pieniny Basin (Z/PB) existed as an oceanic basin located between Central Carpathian plate and Czorsztyn Ridge during Jurassic–Early Cretaceous times. The extremely deep-water pelagic limestones and radiolarites were followed by Albian-Miocene marls and clastic within Z/PB. Major plate reorganization happened during Tithonian-Albian times. The new Atlantic spreading entered the area between the Newfoundland shelf and Iberia. The Jurassic Pangean break-up system in Alpine Tethys was abandoned. The subduction developed along the Alpine Tethys (Z/PB) margin. The rotation of Africa and the spreading in the Eastern Mediterranean caused the Central Carpathian Plate to converge with Europe. The Alpine Tethys was gradually closed. The latest Cretaceous-earliest Paleocene was the time of the closure of Z/PB and the Late Cretaceous flysch of Z/PB Basin was deposited as a part the accretionary prism in front of the Central Carpathian Plate that reached and overrode the Czorsztyn Ridge. The turbiditic and pelagic sedimentation continued in the piggy-back setting until Neogene times. Finally, the Z/PB and accretionary prism deposits were transformed into several nappes, including Złatne Unit (nappe) of the Pieniny Klippen Belt (PKB). The PKB is located in the suture zone between the Central and Outer (Flysch) Carpathians, stretching from Austria to Romania in the Central and Eastern Europe. The tectonic Złatne Unit is best exposed in the western part of PKB in Poland.as well as in the Haligovce - Vel'ký Lipník area in Małe Pieniny Mountains in Slovakia. Type locality is in the Złatne area (Spisz Pieniny Mountains) in Poland The huge olistoliths in Haligovce – Vel'ký Lipník area represent shallow water sequences of the southwestern margin of Alpine Tethys. These olistoliths are surrounded by Upper Cretaceous and Paleogene flysch sequences forming sedimentary mélange.

This research was financially supported by the Polish National Science Center grant NCN – 2019/35/B/ST10/00241 and grant of the AGH University of Krakow (16.16.140.315).

The Tethyan Seaway during the Early to Middle Miocene – new data and a review

Werner E. E. Piller[1]*, University of Graz, Austria (werner.piller@uni-graz.at)
Mathias Harzhauser[2], Natural History Museum Vienna
Matthias Kranner[3], Natural History Museum Vienna
Oleg Mandic[4], Natural History Mesum Vienna
Tayebeh Mohtat[5], Geological Survey of Iran, Tehran
Jahanbakhsh Daneshian[6], Kharazmi University, Tehran

Abstract

The Tethyan Seaway was the connection between the Eastern and Western Tethys which became restricted and finally closed during the Early and Middle Miocene. The uplifted Zagros Mountains split the seaway into two entities, the Iranian Gateway in the northeast and the Mesopotamian Gateway in the southwest. The reconstruction of the seaway is based on sedimentological and paleontological data of the Qom, Asmari and Gachsaran formations predominantly on biostratigraphy. This paper presents an evaluation and new data on the occurrence of the Qom Formation in the Zanjan area (Sheikh Jaber section) of Iran. The Qom Formation there is dominated by marls and sandstones and only subordinated limestones occur. Unusual for the Qom Formation is the high share of volcanic rocks (basalt, tuff, tuffitic marls, lapilli, coarse volcanoclastic components in all types of lithologies) which indicates that the Qom Formation in the Zanjan area belongs either to the Sanandaj-Sirjan Basin or the Urumieh-Dokhtar Basin. Planktonic foraminifers and mollusks, in particular, pteropods, indicate a deposition of the succession in the late Burdigalian to Langhian. The mollusk fauna exhibits a pure Mediterranean character and no overlap with the Indo-Pacific fauna occurs. Both the fauna and the overlying continental deposits of the Upper Red Formation preclude a marine connection along the Iranian Gateway in the Langhian between the Proto-Mediterranean and Indian Ocean, the mollusk fauna also obviates a connection between the Proto-Mediterranean/Indian Ocean and the Eastern Paratethys. The sediments in the Mesopotamian Gateway are represented by the Asmari Formation, which is similar in facies and stratigraphy to the Qom Formation, and the Gachsaran Formation dominated by evaporites and shallow marine sediments. This gateway may have not been completely blocked in the Langhian but the very shallow water connection was paleoceanographically ineffective and not passable for biota such as mollusks.

Late Paleocene-middle Eocene calcareous nannofossils in western Tarim Basin

Xuejiao WANG[1]*, Polar Research Institute of China (xuejiaowang410@hotmail.com)

Abstract

The western Tarim Basin is located between the Tianshan Mountains and the Kunlun Mountains and was situated in shallow epicontinental northeastern part of the Tethys Sea during the Late Cretaceous to Eocene. Three cycles of sea regressions are recorded in Qimugen, Wulagen and Bashibulake formations and PETM (Paleocene-Eocene Thermal Maxmum) event is identified by carbon isotope excursion in Qimugen Formation in previous studies. Here, calcareous nannofossils assembalges from late Paleocene-middle Eocene sediments from three sections (Bashibulake, Kuzigongsu and Simuhana) were correlated to dicuss the biostratigraphy and paleoecology in the Tianshan Mountains area (western Tarim Basin). The third sea transgression occurred concomitant to the Qimugen Formation, and calcareous nannofossil assemblages indicate the highest relative sea level occurred near the middle part of NP9a in the Tianshan Mountains area. The gradually increasing sea level from the base of the Qimugen Formation is dated to the nannofossil zones NP7 to 9a (Thanetian), in which the first occurrence of *Heliolithus riedelii* and of *Discoaster multiradiatus* have been recorded. The highstand of the sea level cycle coincides with increasing *Discoaster* spp. amounts near the Paleocene/Eocene boundary (NP9a-10), which is dated by the occurrence of RD assemblages (namely, *Discoaster araneus* group-*Rhomboaster* spp.). Evidence of regression, observed in the top of Qimugen Formation (NP10-11) corresponds to low abundance and diversity of nannofossils, and is characterized by a rapid increase of *Micrantholithus* spp. in the assemblage. And combining with the previous model of PETM event, the recovery phase may not be recorded completely in the western Tarim Basin. The fourth episode represents a period of shallowing upward in the Kalataer and Wulagen formations, which is dated as CNE12-13 (Lutetian) for the occurrence of *Nannotetrina* spp., *Discoaster bifax*, *Reticulofenestra umbilicus*, *Cribrocentrum reticulatum* and *Chiasmolithus solitus*. The maximum depth of water documented near the boundary of CNE12/13 zone. The presence of a diverse assemblage of discoasters in the top Kalataer to basal Wulagen suggests deposition occurred in oligotrophic, warm water with a connection to the open ocean. Progressive shallowing over time led to the formation of a restricted basin in which only *Coccolithus pelagicus* could survive. Alternating dry and wet condition was shown by large proportion of illite and montmorillonite in the middle Wulagen Formation, indicating that the abrupt disappearance of calcareous nannofossil was mainly controlled by water depth. The fifth major episode of marine incursion is preserved in the middle part of the Bashibulake Formation, which is dated as Zone CNE17 (Bartonian/Priabonian) based on the presence of common *Cribrocentrum erbae*.

The base of the Maastrichtian at the Oslen-Krivodol Peritethyan reference section, Bulgaria: bioevents, isotope events and paleoceanography

Michael WAGREICH[1]*, University of Vienna (michael.wagreich@univie.ac.at)
Docho Dochev[2], Sofia University
Polina Pavlishina[3], Sofia University
Veronika Koukal[4], University of Vienna

Abstract

The base of the Maastrichtian as defined by the GSSP at Tercis-de-Landes, France, is currently in investigation by the newly installed Maastrichtian Working Group. Originally, the Campanian-Maastrichtian boundary (CMB) was set at a mean of marker bioevents, near the guide event of the first occurrence (FO) of the ammonite Pachydiscus neubergicus, estimated to be ca. 35 ka younger than the GSSP level. The main calcareous nannofossil marker so far provides the last occurrence (LO) of Uniplanarius trifidus, estimated at ca. 750 ka younger. Paleogeographically, Tercis was situated in the Tethys-Atlantic transition to the cooler northern temperate realm.

A largely similar Peritethyan paleogeographic position at the northern Tethyan-European margin is provided by the Upper Cretaceous sedimentary successions cropping out in the western Fore-Balkan Mountains area in Bulgaria. One of the most representative section comprising the Upper Campanian-Lower Maastrichtian interval is the Oslen-Krivodol section, situated in the western part of the Central Balkan–Fore-Balkan Zone in the northern segment of the Balkan Orogen.

At the section of Oslen-Krivodol, a 7 m succession of glauconitic limestones, clayey to nodular limestones and chalky sediments is exposed that includes inoceramids and belemnites. The lower part is composed of green to greenish glauconitic limestones (Darmantsi Formation), overlain by thin- to medium bedded limestones, clayey and nodular limestones (Kunino Formation). Belemnite rostra occur in the entire section, whereas inoceramid bivalves were collected from one level in the upper part of the Kunino Formation. A complete nannofossil zonal succession could be established, from the uppermost Campanian to the lowermost Maastrichtian, with subzones UC15cTP, UC15deTP, UC16aTP (uppermost Campanian), and UC16bTP (basal Maastrichtian). The nannofossil bioevent for the base of the Maastrichtian, the LO of U. trifidus, is at 3.25m in the section. Strontium isotope stratigraphy indicates the CMB interval around values of 0.707728 ±0.000004. Additional nannofossil bioevents in the CMB interval include the FO and LO of Microrhabdulinus ambiguus below those two inferred CMB levels, and the sudden decrease of warm-water nannofossil indicators like Watznaueria spp., which seems to indicate a threshold crossing for global cooling along the CMB carbon isotope event. Higher in the section, Arkhangelskiella maastrichtiensis s.str. occurs.

Two dinocyst zones have been recognized in the section: the upper Campanian Areoligera coronata and the lower Maastrichtian Cerodinium diebelii Zone. Their boundary is marked by the last occurrence of typical Campanian taxa (Odontochitina, C. robusta, C.horridum, A. fenestra) and the appearance of characteristic Maastrichtian forms (C. diebelii, M. carpentierae,

Glaphyrocysta).

Only one level from the upper part of the Kunino Formation have yielded abundant, but badly preserved (as internal moulds) inoceramid bivalves. The inoceramids are represented mainly by the genus Cataceramus, but Endocostea is also present: Endocostea typica Whitfield, 1880; Cataceramus pallisieri (Douglas, 1942); Cataceramus subcircularis (Meek, 1876) and Cataceramus barabini (Morton, 1834). Based on the presence of E. typica we can indicate the eponymous inoceramid zone at the base of the Maastrichtian.

The CMB interval is generally marked by global cooling and the broadly negative Campanian-Maastrichtian Boundary carbon isotope Event, with positive peaks (CMBE1 to 5).

The opening time constraints of both Bangong-Nujiang Ocean and Neotethys Ocean: evidences from both stratigraphy and palaeobiogeography in the Qinghai-Tibet Plateau

Qi Ju[6], School of Earth Sciences & Engineering, Nanjing University

Abstract

The opening time of both the Bangong-Nujiang Ocean (or the Mesotethys Ocean) and the Neotethys Ocean have been a focus of debate. Several paleogeographic models have been proposed. We have undertaken several years of hard fieldwork in various regions in the Tethys Himalaya area, the Lhasa Block, the South Qiangtang Block and eastern Myanmar, with the purpose to establish the correlations of different tectonic blocks as well as to constrain the opening time of both Bangong-Nujiang and Neotethys oceans. Our studies indicate that: (1) The South Qiangtang Block rifted away from the Gondwanan margin during the Artinskian time (~290 Ma). And shortly after its departure, a rifted valley developed within this Block during the late Kungurian time. (2) The Permian of the Lhasa Block is very stable, which is characterized by a stable transition from glacio-marine diamictes during the Early Permian to carbonated during the Middle and Late Permian. Also, some faunas (such as late Kungurian Vjalovognathus-Mesogondolella conodont assemblage and Capitanian Nankinella-Chusenella fusuline assemblage) are characteristic faunas in the Lhasa Block. (3) The Neotethys Ocean must have opened before the late Kungurian time as evidenced by the contrast depositional sequence between the Lhasa and Tethys Himalaya. Also, the development of Middle Permian seamount within the Yarlung-Tsangpo suture zone as well as the distribution pattern of the typical Shanita-Hemigordiopsis foraminiferal assemblage both suggest the existence of a Neotethys Ocean during the Middle Permian time.

In conclusion, both the Bangong-Nujiang Ocean and Neotethys Ocean have opened in different time during the Permian time. So, the Cimmerian Continent is much more complex than previously recognized.

Abstract

The Altaids and Tethysides are two considerable orogenic systems on our planet. The closure of the Paleo-Asian Ocean (PAO) formed the Altaids, and the closure of the Tethyan Ocean (TO), Tethysides. Most previous reconstructions regarded the Tarim-Alxa-North China as a long continent chain in the Paleozoic that blocked the internal TO from the external PAO. However, it is controversial how and when the key continental blocks, including Tarim, Alxa and NC, formed a continental chain. We summarize new advances in the tectonic evolution of the intervening orogenic belts to address the Permian–Triassic amalgamation for the Altaids-Tethysides interaction. Paleogeography and paleomagnetism data show that Kazakhstan, Tarim, Alxa and South China shared similar Gondwana affinity, but the NC was different from these blocks. In particular, recent paleomagnetic studies indicate that the Alxa block was not unified with NC until Permian. In the late Paleozoic, there were still some wide oceans between Tarim, Alxa, and NC. Therefore, there was no such integrated Tarim-Alxa-NC blockage that existed since the early Paleozoic. Systematical petrological and isotopic data on the ophiolites in the Altaids verify that some oceans in the western Altaids (West Tianshan and West Junggar) had origins from the TO, indicating that the TO was located not only to the south of the Tarim block, but also to some areas north to the Tarim in the late Paleozoic. A complicated archipelago system may have existed in which some intra-oceanic arcs might link some of those continental blocks, forming irregular boundaries between TO and PAO. Considerable interactions might have happened between the Altaids and Tethysides, in a way similar to the Pacific plate penetrating into the Atlantic ocean through the Caribbean Sea. There was one larger, major composite continental mass, composed of Kazakhstan, Tarim, Alxa, Qaidam, NC, South China (SC) and Indochina (INC) blocks, called the KTANSI, which finally formed in late Permian to Triassic. This is based on the final amalgamation timing of the intervening orogens, which all converge to the late Permian–Triassic. The South Tianshan, the major suture welding Kazakhstan orocline and Tarim, was capped by a Triassic accretionary basin. The eastern Tianshan shows its similar Triassic final amalgamation history. The Tarim block was amalgamated with the Qaidam block by closing oceans along the

Beishan and Eastern Kunlun orogens in the Permian–Triassic. Paleomagnetic data suggested that the Alxa block was not part of the NC until Permian, and a transform boundary was proposed between them until Triassic. In Triassic, there was a unified Kazakhstan-Tarim-Qaidam-Alxa-NC continental chain in the northern part of East Asia, joined by the SC along the Qinling-Dabie-Sulu, which was amalgamated with the INC along the Ailaoshan–Red River orogen in the Triassic. These intervening orogens were almost terminated in the Triassic, which finally formed a gigantic S-type continental chain. Together with the “giant tadpole” that are composed of the Siberia and Tuva-Mongol orocline, complicated continental chains and their multiple oroclines played an important role in the architecture of orogens and continental growth of East Asia.

Early Triassic anachronistic microbial and pisoid-facies carbonates in the eastern Paleotethys

Katsumi Ueno[1]*, Department of Earth System Science, Fukuoka University (katsumi@fukuoka-u.ac.jp)
Thasinee CHAROENTITIRAT[2], Program in Energy Geoscience, Faculty of Science, Chulalongkorn University, Thailand
Yoshihito KAMATA[3], Graduate School of Life and Environmental Sciences, University of Tsukuba, Japan

Abstract

In view of biocommunity development through the Earth history, the Early Triassic lasting for some 5 m.y. is unique in continuing biodiversity suppression after the Permian–Triassic boundary (PTB) mass extinction. In this period, carbonate deposits showed unusual, somewhat anachronistic features, such as dominating microbialites, thrombolites, pisoids (giant ooids), and the poverty of skeletal grains, probably reflecting peculiar marine environmental conditions after the catastrophic PTB event. Primary dolomite production is also common. We examined a continuous, latest Permian to Middle Triassic carbonate succession distributed in the Lampang area of Northern Thailand to closely investigate its Early Triassic sedimentary and biotic features.

The Lower Triassic in this area has been attributed to the Phra That Formation of the Lampang Group, and previous studies described the main lithology of the formation as being predominant in siliciclastic rocks. Thus, the examined carbonate succession is regarded as time-equivalent with the Phra That Formation but showing different lithofacies. The Early Triassic succession studied herein consists mainly of dolostone and dolomitic limestone and directly overlies conformably latest Permian *Palaeofusulina*- and *Colaniella*-bearing limestone. It is subdivided lithologically into two parts. The lower (basal) portion (ca. 100–150 m thick) is composed of bedded to massive dolostone and dolomitic limestone with laminated microbialites made by clotted micritic particles in some levels. Sporadically occurring *Postcladella kalhori* supports an Induan age for this interval. Tiny crystals of pyrite (partly hematite?) are sometimes observed in fine-grained dolomite beds, and thin layers consisting of ooid (rarely pisoid) grains are also recognized in some dolomitic limestone beds. The latter represents inflow deposits by storm and other intermittent events and characteristically contains broken ooids, which suggest strong reworking and/or possible breakdown by desiccation. Overall, the lower part of the succession presumably exhibits an intertidal to supratidal environment. The middle–upper portion (ca. 700–750 m thick) is dominated by cross-laminated oolitic and pisolitic dolomitic limestone and dolostone. A broad Olenekian age is supposed by rarely yielded monotonous and restricted foraminiferal assemblages composed of *Postcladella*? (or primitive *Arenovidalina*?) and "*Glomospirella sygmoidalis*". An uppermost subtidal to intertidal environment is suggested for the depositional setting of this dolomitic limestone and dolostone interval in the studied carbonate succession, based on the abundant occurrence of ooids and pisoids. Then, this middle–upper part is succeeded by micritic limestone of the Middle Triassic Pha Kan Formation,

which contains the Anisian *Citaella dinarica* assemblage.
The present Early Triassic succession in Northern Thailand is characterized by unusual foraminiferal features and carbonate lithology, such as restricted faunal diversity and anachronistic laminated microbialites and pisoid-rich dolomitic limestone, while its conspicuous carbonate production represented by >800-m-thick strata. The studied carbonates formed in the eastern Paleotethys would have good potential for elucidating shallow-marine paleoenvironments in the process of recovery from the PTB extinction. In addition, this is the first documentation of Early Triassic carbonates and foraminifers in Southeast Asia.

Late Neoproterozoic–Cambrian eclogites and high-pressure granulites in the Central Qilian terrane (China) record the earliest subduction of Proto-Tethyan Ocean in the eastern Tethysides

Hao WANG[1]*, Xinjiang Institute of Ecology and Geography , Chinese Academy of Sciences (paulwh@126.com)
Wenjiao XIAO[2], Xinjiang Institute of Ecology and Geography , Chinese Academy of Sciences
Rui LI[3], Xinjiang Institute of Ecology and Geography , Chinese Academy of Sciences

Qigui MAO[6], Xinjiang Institute of Ecology and Geography , Chinese Academy of Sciences

Abstract

The Central Qilian terrane (CQT) of the northern Tibetan Plateau played a key role in the tectonic evolution of the Proto-Tethyan Ocean in the Tethysides, but its formation and tectonic attribution have been hotly debated. Here, we report the discovery of eclogites and HP mafic granulites in the Beidahe Complex of the western CQT. These occur as blocks of various sizes within a sequence of metavolcanic–sedimentary rocks, exhibiting typical a ‘block-in-matrix’ and thrust imbrication structure. The eclogite facies metamorphic rocks preserve distinct mineral assemblages and textures corresponding to prograde, peak, and retrograde metamorphism. By combining phase equilibrium modelling with SHRIMP and LA-ICPMS U–Pb dating of metamorphic zircon, sphene, and rutile, the Late Neoproterozoic–Cambrian (ca. 553–516 Ma) eclogite facies peak with low thermal gradients of 10–14℃/km, Cambrian (ca. 515–506 Ma) post-peak decompression and Ordovician (ca. 495–455 Ma) cooling histories for these metabasic rocks have been restored. These constitute hairpin-type clockwise pressure–temperature–time (P–T–t) paths depicting in detail the sequence of deep subduction and subsequent exhumation in Central Qilian during the Late Neoproterozoic to Early Palaeozoic. Our new findings suggest that the CQT represents a Japan-type arc-accretionary system that formed as a result of the North Qilian oceanic plate, one of the major branches of the Proto-Tethys Ocean, being subducted southward. Eclogites in the Beidahe Complex in western CQT offer the earliest (ca. 553 Ma) metamorphic record of subduction in the Qilian orogen, indicating that the North Qilian Ocean commenced subducting southward prior to the Late Neoproterozoic.

Abstract

The evolution of eastern Paleo-Tethys, between the South China and Indochina blocks, recorded the whole process of rifting from Gondwana and their northward migration and convergence. To understand the tectonic implications, the structure geology, arc-related magmatism, and matrix of ophiolitic mélange were realized in the classic Indochina orogenic belt. This Mesozoic orogenic belt consisted of three segments of Ailaoshan, Song Ma, and Song Chay, which located in the North Vietnam-Southeast Yunnan region. Based on our regional comprehension, we reviewed the previous structure, zircon U-Pb dating, and Lu-Hf isotopic analyses from the Ailaoshan, Song Ma, and Song Chay ophiolitic mélange. Accordingly, we subdivide the matrix of the ophiolitic mélange into four parts (M1, M2, M3, and M4). M1 is mainly located in the middle segment of the Ailaoshan-Song Ma belt. It shows the age peaks of 440 Ma and 960 Ma with εHf(t) values of -19.6 ~ +10.3. M2 is mainly located in the NW segment of the Ailaoshan-Song Ma belt, showing a dominant age peak of ~260 Ma. Particularly, it has εHf(t) values of -28.9 ~ +8.1. M3 is mainly located in the SE segment of the Ailaoshan-Song Ma belt, showing peaks at ~250 Ma, 440 Ma, and 960 Ma with εHf(t) values of -21.9 ~ +10.1. M4 is mainly located in the Song Chay belt, showing peaks at ~310 Ma, 470 Ma, 610 Ma, 770 Ma, and 965 Ma with εHf(t) values of -28.2 ~ +10.8. The geochronological data of the detrital zircon from the matrix of the Ailaoshan, Song Ma, and Song Chay ophiolitic mélange zone, documents a temporal heterogeneity between the M1, M2, M3, and M4 units at 310-270 Ma, 265-250 Ma, 245-240 Ma, and 310-255 Ma, respectively. The different components and provenances of each unit reflect a strike-parallel heterogeneity. The M1 unit was mainly sourced from the Paleozoic sedimentary rocks of the IB. The main provenance for the M2 unit is Emeishan large igneous province (ELIP). The magmatic arc developed in the IB provided the materials for the M3 unit, and the detrital materials of the M4 were mainly sourced from the SCB. The M1, M2, M3, and M4 units contain information from different evolutionary stages, likely recording the comprehensive history of the ancient oceanic basin. Importantly, our results demonstrate that both the active continental margin of the IB and the passive continental margin of the SCB acted as provenance sources that supplied a significant amount of detrital material in the ophiolitic mélange matrix, indicating a limited ocean of Paleo-Tethys. Combined with the structure magmatism analysis, the Indochina orogenic belt recorded

that the subduction and obduction were coexisting. This phenomenon creates the heterogeneity in this orogenic belt and provides a classical anatomical example of the different manifestations (subduction and obduction) during two-block interaction. It is of great significance in recognizing the relationship between the Paleotethys and the Panthalassa (Paleo-Pacific).

Revisiting the Structure and Stratigraphy of the Bentong-Raub Suture Zone: Insights from Field Investigation and Geochemical Analysis

Norasiah Binti SULAIMAN[1]*, The National University of Malaysia (UKM)
(norasiahs@ukm.edu.my)
Mohd Basril Iswadi BASORI[2], National University of Malaysia
Muhammad Ashahadi DZULKAFLI[3], National University of Malaysia
Azrin AZMI[4], National University of Malaysia
Muhammad Fuad RAZALI[5], National University of Malaysia

Abstract

The Bentong-Raub Suture Zone, located in Peninsular Malaysia, is part of a north-south trending lineament that extends from west Thailand through west Malaysia and into east Indonesia, representing Paleo-Tethys. This study utilizes field investigation, structural analysis, biostratigraphy, and geochemistry to extensively reexamine the structure and stratigraphic framework of the units within this suture zone. This study updates lithological units in the suture zone that extend beyond earlier proposed boundaries. The suture zone is characterized by the association of ophiolitic units, localized tectonic melange, and sedimentary deposits. The sedimentary deposits are deformed (folded, faulted, and sheared) and show blocks in a matrix fabric in some areas, forming a chaotic mass representing accretionary remains that structurally overlay the ophiolite unit. The limestone block in the mélange is determined to be of Early-Middle Triassic age based on the discovery of Triassic foraminifera, while siliceous-chert rocks exhibit Late Devonian to Middle Triassic age based on radiolarian biostratigraphy. Geochemical data from mafic rocks of the ophiolitic units hint at a possible origin from oceanic crust, while geochemical analysis of the siliceous-chert rocks affirms a biogenic origin in pelagic-oceanic basin and continental margin environments. The ophiolite was emplaced in a supra-subduction zone-type due to intra-oceanic subduction initiation as a result of the collision between the Sibumasu and Indochina blocks. Tectonic transport direction reflects collisional influence, yet disrupted deformation patterns imply strike-slip movements in the northwest-southeast and northeast-southwest directions. The discovery of the Middle Triassic radiolarian biozone suggests an open Palaeo-Tethys basin in Peninsular Malaysia up until the Middle Triassic, and the age of the mélange limestone block hints at accretion post-Middle Triassic. This comprehensive study contributes valuable insights into the geological evolution of the Bentong-Raub Suture Zone and its regional tectonic context.

A PALEOENVIRONMENTAL MODEL FOR THE RUS FORMATION: FACIES CHARACTERISTICS AND THEIR SEDIMENTARY ENVIRONMENTS

Osman Abdelghany[1]*, UAE University (osman.abdelghany@uaeu.ac.ae)
Abdel-Rahman Fowler[2], UAE University
Ahmed Gad[3], Ain Shams University, Egypt
Mahmoud Abu Saima[4], UAE University

Abstract

To the south of Al-Ain, in southern Abu Dhabi Emirate, a Lower Eocene to Miocene mainly marine carbonate sequence is well exposed at Jabal Hafit Mountain. This sequence includes the Rus Formation (lowest, no base exposed) of Lower Eocene age, overlain by the Middle to Upper Eocene Dammam Formation, followed by the Lower Oligocene Asmari Formation. The Dammam and Asmari Formations at Jabal Hafit have been the targets of numerous biostratigraphic studies, while the Rus Formation has received scant attention. The Rus Fm regionally is composed of a very shallow water platform sequence that includes significant evaporites (gypsum deposits). This is true for the exposures in Qatar, Saudi Arabia, Bahrain, Kuwait, Iraq and Oman. The Rus Formation in Jabal Hafit is markedly different in lithologies, with no clear evaporite horizons. It includes three members – a) the recently defined Mubazzara Member of nodular brown fine-grained cherty limestones, b) the Wadi Tarabat Member of white coralgal limestones, and c) the dolomitic Hili Member Alveolinid limestones.. A paleoenvironmental analysis of the Rus formation is the objective of this study, since no previous work has been published on this topic for the Rus Formation. Systematically sampled carbonate rocks were thin sectioned for microlithofacies analysis and micro-paleontological survey. For the Mubazzara Member the carbonate rocks were found to be mudstone-wackestones that contained planktonic foraminifera, ostracods, echinoids and sponge spicules. Less abundant Nummulites and Discocyclina fossils were present. The Wadi Tarabat Member is a packstone-grainstone with oolitic facies; stromatolitic facies including large Orbitolites; and miliolid-rich facies with Nummulites and Alveolina. The Hili Member is found to be a dolomitized wackestone-packstone rich in minute limonite particles, and hosting abundant disarticulated fossils of small Nummulites, Assilina and algal bodies. The three Rus Formation Members appear to describe a succession of environments on a carbonate ramp with tidal flat to inner shelf lagoon represented by the Hili Member, an above-wave-base shoal water environment for the Wadi Tarabat Member, and an open marine environment for the Mubazzara Member. The Rus Formation at Jabal Hafit preserves the deposits at the edge of the regional evaporitic carbonate platform that dominated the Arabian Peninsula in the Early Eocene. The carbonate ramp probably formed the margin of the Muthaymimah Trough.

Newly discovered Late Paleozoic magmatic rocks link to Paleo-Tethyan evolution in Hainan Island, South China

Lei WANG[1]*, Wuhan Center, China Geological Survey (Geosciences Innovation Center of Central South China) (wlei_a@mail.cgs.gov.cn)
Guang-Yue Cao[2], Chinese Academy of Geological Sciences
Xiang-Dong Wang[3], Wuhan Center, China Geological Survey (Geosciences Innovation Center of Central South China)
Dai Zhou[4], Wuhan Center, China Geological Survey (Geosciences Innovation Center of Central South China)

Abstract

The Song Ma suture zone in Southeast Asia is a segment of the main suture zone of the Paleo-Tethys Ocean, whereas the suture zone extends to South China is not well constrained. Previous studies have focused on metabasites and high-pressure metamorphic rocks from Hainan Island to discuss this issue, i.e. Bangxi-chengxing tectonic zone and Mulantou Complex. In this study, we present SHRIMP and LA-ICP-MS U-Pb dating, elemental and Nd-Hf isotopic data for newly discovered Late Paleozoic magmatic rocks link to Paleo-Tethyan evolution in Hainan Island.

The geochronological data show that three granitoids from northeastern Hainan Island yield zircon U-Pb ages between 366.4±2.2Ma and 370.4±2.4Ma, indicating a Late Devonian intrusive age. They exhibit unique geochemical signatures, characterized by enrichment in light rare-earth element, and large-ion lithophile elements (e.g. Rb, Th, U) with positive Pb spikes. Additionally, they show depletion in high-field-strength elements like Nb, Ta, and Ti, along with low contents of Sr and P. Isotopically, these rocks show uniform whole-rock Nd isotopic compositions with negative epsilon Nd values, but variable zircon Hf isotopic compositions and epsilon Hf values. The model age of Nd and Hf isotope are coincide with those of Precambrian metamorphic basement in Hainan Island. Titanite and apatite samples for four metabasites from western Hainan Island yield U-Pb intercept ages between 254.3±4.2Ma and 267.4±3.0Ma, indicating a Late Permian emplacement age. They were mainly alkaline-subalkaline basalt, with OIB-like and MORB-like geochemical features. All samples show positive epsilon Nd values ranging from 2.93 to 7.13.

Synthesizing the published data in Hainan Island, alongside the suture zone of the Paleo-Tethys Ocean, we propose that tectonic affinity of Hainan Island during the Late Paleozoic belongs to an arc-basin system related to the Paleo-Tethyan evolution from Tibetan plateau extended to South China. Late Devonian granitoids and Late Permian metabasites record the early-stage subduction of Paleo-Tethys Ocean and late-stage spreading of back-arc basin, respectively.

Late Paleozoic sedimentary successions and basin structure variation of the Baoshan-Shan Block (China-Myanmar)

Xiaochi JIN[1]*, Institute of Geology, Chinese Academy of Geological Sciences (jinxchi@sina.com)

Abstract

The Baoshan-Shan block is a Gondwana-derived continental block straddling western Yunnan, China and Myanmar. It is separated from the Tengchong block and the Tenasserim unit to the west by the Nujiang and Shan Boundary faults, and from the Changning-Menglian belt and the Inthanon zone to the east by the Lancangjiang, Kejie, Nandinghe and Mae Yuam faults.

The Baoshan-Shan block has rather well-developed Paleozoic successions. But a hiatus resulted from the mid-Carboniferous (or Namurian) uplift is apparent and has varied magnitudes over the block. The mid-Carboniferous uplift is a widely recognized event in east Gondwana and its northern marginal region, where the Baoshan-Shan block was located. It changed the relief of the Baoshan-Shan block, interrupted the sedimentation on it, and caused erosion over a large area. Consequently, Late Carboniferous sediments are hardly seen on the block. Early Permian siliciclastics (120-150 m) with glacio-marine sediments were deposited on tilted Early Carboniferous limestones in the northern Baoshan block (referring to the Yunnan part) and on Devonian siliciclastics in the southern Baoshan block. The southwestern Baoshan block through to the Shan block (referring to the Myanmar part) stayed emerged. Deposition of limestones started around the Sakmarian/Artinskian boundary in the northern and southern Baoshan block. But was soon disrupted by the eruption of the Woniusi Basalts, which filled up the basin on the Baoshan block, with a thickness of ca. 700 m in the northern part and about 500 m in the southern part. The southwestern part and Shan block stayed as highland and was not reached by the basalts. This eruption resulted in a rather flat surface on the Baoshan block.

About the Roadian time, coastal clastic sediments, mainly red beds, formed on a weathered surface of the Woniusi Basalts in northern and southern Baoshan block, and on Middle Devonian limestone in southwestern Baoshan block, but are barely reported in the Shan block. Carbonate deposition with a transgression somewhat in the early Wordian took place in the whole Baoshan-Shan block. Carbonate formations rest conformably on the Roadian clastic deposits on Baoshan block. But in the Shan block, they rest on (often Middle) Devonian or older sediments. This round of carbonate deposition sustained through to at least the Middle Triassic in most places of the Baoshan-Shan block, resulting in the formation of thick carbonate successions.

Such an architecture of Late Paleozoic –Triassic sedimentary successions shows that the basement of the Baoshan-Shan basin as whole stayed stable, only in the Baoshan area (about 1/5 of the whole), block-faulting happened in the early Permian. It was in the Middle Permian the whole block submerged accepting carbonate deposition, which was more a result of an eustatic sea level rise. A less interrupted carbonate environment continued to at least the Middle Triassic.

Nuretdin Kaymakci[6], Department of Geological Engineering, Middle East Technical University, Ankara, Turkiye

Abstract

This study deals with the geodynamic evolution of Eastern Turkey, elucidating the temporal and spatial dynamics of sedimentary and tectonic processes in the Oligo-Miocene. Initiated by the convergence of the Arabian and Eurasian plates around 35 Ma, this geological activity induced notable crustal shortening and uplift across Eastern Turkey, the Lesser Caucasus, Talysh Mountains, and the Greater Caucasus, enhancing sediment deposition in adjacent basins due to increased erosion in uplifted terrains. A pivotal outcome of these tectonic shifts was the formation of the Paratethys, a vast inland sea that experienced episodic isolation from global oceans, fostering unique marine life by the late Eocene. Despite its significance, the precise chronology of the Paratethys' inception and regression remains in debate.

Aiming to pinpoint the timing of the Paratethys' progression in Eastern Turkey and offer detailed spatio-temporal insights into its development, this study includes a suite of integrated stratigraphic techniques. These include marine biostratigraphy, magnetostratigraphy, strontium (Sr), and neodymium (Nd) isotope analyses, alongside low-temperature thermochronology. The investigation targets Miocene marine lithologies across Eastern Turkey to the Iranian border, with focus areas in Bölükova and Çayırlı (Erzincan), Yedisu, Hamamlı, Tekman, Aşkale (Erzurum), and Çobanbeyi (Ağrı).

Analyzing 278 magnetostratigraphic samples from Hamamlı and Bölükova, alongside over 200 biostratigraphic samples for foraminifera and nannofossil content, the study also utilizes 17 samples for Sr- and Nd-isotope dating to ascertain the ages and depositional environments of intercalated carbonates. Furthermore, five samples were analyzed by low-temperature thermochronological techniques and their time-temperature graphs were conducted.

Findings suggest the sections' youngest ages align with the late Burdigalian, placing the Hamamlı section within the C6 Chron (20.7-19.05 Ma). Initial Nd isotope data suggest a Mediterranean and Indian Ocean connection during the Burdigalian, indicating the youngest marine deposits in Eastern Turkey formed within an open marine setting linked to global oceans.

Briefly, this study contributes significantly to understanding the geodynamic interplay between continental collision processes and marine sedimentation in Eastern Turkey, underscored by the

Arabian-Eurasian plate convergence.

Abstract

The process of rifting, followed by oceanic opening and subsequent development of post-rift passive margins, constitutes well-studied phases in the extensional processes shaping the formation of Earth's oceans. A critical aspect connecting these stages involves accurately quantifying the extensional activity that varies throughout the processes. In collisional orogenic settings, ancient passive continental margins frequently undergo either tectonic exhumation or significant burial, leading to the obscurity of their pre-existing configuration due to the involvement of crustal shortening processes.

In the area of the Vienna Basin, the main sedimentary succession overlying the crystalline basement is divided into three tectonostratigraphic units; the autochthonous Mesozoic unit, the allochthonous unit with different tectonic nappes, and the Miocene sedimentary rocks of piggy-back and pull-part basin systems. During the Middle Jurassic period, the region was located in a rifting zone of the Penninic Ocean, which transitioned to a passive margin basin setting with the deposition of post-rift sediments extending into the late Cretaceous. Across the Vienna Basin area, Austria, the rocks spanning from syn- to post-rift stages are closely linked with hydrocarbon formation and accumulation. In particular, the Mikulov Formation comprising deep marine marlstones deposited during the Late Jurassic is considered the major source rock pod for conventional hydrocarbons. However, due to the late Cretaceous to Paleogene structural deformations and the Miocene basin subsidence, the precursor rifting and passive margin strata preserve rarely the original configuration and remain largely underexplored. According to previous research, the passive margin phase is marked by notable age discrepancies attributed to varying onsets of syn-rift extension in the Alpine Tethys or Penninic oceanic realm along the peri-Tethyan margins. This study aims to investigate the extensional activity by evaluating the subsidence linked to the opening of Alpine Tethys beneath the Vienna Basin. Through utilizing drilling data and employing 1D basin modeling techniques, we quantify sedimentation rates and therefore place constraints on the effects of extensional faulting on rifted margin(s). The numerical 1D modeling method takes into account the pre-nappe-staked configuration (as well as Paleogene - Miocene sequences), whereby the thickness and properties of the 1D pseudo model layers are painstakingly collected from the available wealth of borehole and literature data. Although we were unable to apply the extensive organic geochemical database to 1D modeling calibration

(accounting for the tectonically displaced nappe-stacking geometry), our results demonstrate consistency between the various modeling scenarios. Our findings reveal that the Late Jurassic passive margin phase (during the period of Mikulov Formation) exhibits markedly lower subsidence rates (ranging from 140 to 170 m per myr) compared to both the underlying syn-rift phase and the subsequent thermal subsidence phase. This underscores the presence of significantly slower extensional trend including subsidence and faulting in the Late Jurassic beneath the Vienna Basin. The observation of elevated thicknesses exceeding 1.5 km indicates that sourcing materials underwent a considerably faster rate of accumulation compared to the computed post-rift subsidence.

Abstract

The Alpine Tethys originated during the Pangean breakup in the Early Jurassic. This oceanic system constituted the extension of the Atlantic system, so the Atlantic Tethys name was also being used. The rocks deposited in the North-Eastern Part of the Alpine Tethys realm are recently exposed mainly in the Pieniny Klippen Belt and Outer Carpathians in Austria, Czech Republic, Slovakia, Poland, Ukraine and Romania.

Several evolutionary stages could be distinguished in the Western Outer Carpathians development:

1/ The synrift–postrift stage is expressed by rifting of terranes off the major continent and opening of oceanic basins, formation of passive margins and basins with the attenuated crust. The opening of the Alpine Tethys and formation of two major basinal domains – the northern Magura and the southern Złatne/Pieniny basins occurred during this stage. These domains were separated by the intraoceanic submarine swell - Czorsztyn Ridge. The basins gathered deep water deposits, mainly radiolarites cherty limestones and synrift clastics, the shallow-water carbonates were deposited on the basin's margins and on the intraoceanic swell.

2/ The synorogenic, contractional, collisional stage that took place in Cenomanian–Eocene is characterized by development of subduction zones along the active margin, partial closure of oceanic basin, partial destruction of ridges, formation of deep-marine flysch basins, development of accretionary prism and partial closing of oceanic basins. At that time the flysch sedimentation occurred in the Alpine Tethys. Thick complexes of sandy-muddy and muddy-sandy turbidites were deposited within the shortening Magura and Złatne/Pieniny basins. The subaqual mass movements were characteristic for that stage of development. They were accompanied by the turbiditic sedimentation and as a result, the olistostromes were formed. Intense gravity mass sedimentation occurred in the Złatne/Pieniny Basin during the Late Cretaceous, producing chaotic sediments of mélange-type with olistoliths of Jurassic rocks. Slightly later, in the Late Cretaceous–Paleocene, olistostromes formations were frequently deposited in the southern part of Magura Basin, as an effect of accretionary prism overriding the Czorsztyn Ridge. The characteristic morphology of the Pieniny Klippen Belt is connected with the occurrence of the limestone klippen standing out in the landscape. These klippen are results of separation of olistoliths from the soft mélange matrix by erosion. The carbonate deposits developed also along the northwestern margin of the Alpine Tethys. These rocks are known from olistoliths occurring in

the mélanges of the Magura Nappe and Subsilesian-Ždanice-Waschberg units. The largest olistoliths occurs in the Kurovice in Czech Republic.
3/ The late orogenic stage, Eocene–Miocene in age, is characterized by further development of accretionary prism closing of oceanic basins, final destruction of ridges and development of remnant flysch basins. The Alpine Tethys ceased to exist during this stage. The remnant flysch basins became part of the Paratethys.

Abstract

Paleogeographic analysis has shown that the continents of Gondwana, Baltica, Laurentia, Siberia, South China and North China, as well as several smaller plates and other tectonic elements were present during Paleozoic times. These elements included Indochina and Sibumasu, presently in South-East Asia. The Prototethys (Paleoasian) Ocean extended between Siberia, Baltica and the Asiatic plates. This ocean originated perhaps during late Cambrian – Early Ordovician times. It separated Indochina and South China plates.

Paleotethys Ocean existed during Paleozoic and Early Mesozoic times. It was located between the Gondwana continent and Avalonian ribbon of terranes that broke-off Gondwana and moved north. Indochina belonged to this ribbon,

Indochina collided with South China along Song Ma – Truong Song – Ailaoshan suture during latest Silurian-earliest Devonian times. In northwestern Vietnam, the late Silurian Song Chay complex granitoid is connected to this event. This collision was followed by the subduction of the Paleotethys Ocean below Indochina and the formation of a new oceanic basin between Indochina and South China recorded by the ophiolite belt consisting of several complexes and formations. This basin was closed during Permian-Triassic times by the Indosinian Orogeny marked by magmatic, metamorphic, and deformation events in various structural zones.

The Sibumasu belonged to the Cimmerian Chin of microcontinents that was detached from Gonwana during late Paleozoic times opening the Neotethys Ocean. The collision of these microcontinents with Indochina trigger the Indosinian Orogeny. This orogeny was concluded at the Triassic-Jurassic boundary, leading to closure of Paleotethys and the consolidation of a new large Chinese-SE Asian plate. The Indosinian orogeny events are marked by ophiolites and related structural zones along Raub-Bentong, Sra Kaeo and Nan-Uttaradit suture between Sibumasu and Indochina and Song Ma- Ailaoshan suture between Indochina and South China.

This research was financially supported of the Vietnam Ministry of Education and Training (VMOET) under grant number B2023-MDA-08.

Study on coal-bearing deposits of the Lower Gosau Subgroup (Turonian to Campanian) in the Northern Calcareous Alps, Austria: High-resolution insights into the paleoenvironment

xinxuan Xiang[1]*, University of Vienna (xiangxxcumtb@hotmail.com)
Eun Young Lee[2], University of Vienna
Wagreich Michael[3], University of Vienna

Abstract

During the late Cretaceous, the southward subduction of the Penninic plate resulted in the formation of a series of basins at the front edge of the Austroalpine microplate. The sediments deposited in these basins, overlying the Northern Calcareous Alps, and forming a terrestrial to deep-water succession, are recognized as the Gosau Groups. The Gosau Group reflects the variation of paleoenvironment from the late Cretaceous until the Eocene. It has been divided into the Upper Gosau Subgroup and the Lower Gosau Subgroup according to the sedimentary facies. The Lower Gosau Subgroup indicates a transitional environment from terrestrial to shallow water, composed of fluvial, lacustrine, and shallow marine sediments deposited during Turonian to Santonian-Campanian times. The Upper Gosau Subgroup is characterized by deep water successions up to the Eocene in age. The shallow-to-deep environmental transition was derived from the subsidence of the continental margin, associated with the subduction movements. This study investigates environmental signals by analyzing coal-bearing deposits in the Lower Gosau Subgroup to reconstruct. We selected seven outcrop sites including coal seams ranging from the Turonian to Campanian in Austria, which showed fluvial and/or lacustrine depositional settings, and collected fine-grained sediment and coal samples. Based on industrial analysis and vitrinite reflectance, the coal samples were evaluated as low to medium ranks. Our results indicate a wide range of variations in siliciclastic, oxides, organic matters, and clay contents that are related to changes in the depositional environment and water energy. These correspond to occasional occurrences of pyrite and carbonates, which could have been caused by interaction with seawater intrusions. Changes in the maceral contents could also be influenced by varying (ground)water levels. Our study suggests that the coal-bearing sediments of the Lower Gosau Subgroup in Austria were deposited in unsteady environments and occasionally affected by seawater, which might correspond to the short-term sea-level fluctuations reconstructed for the Late Cretaceous.

Abstract

The Permian–Triassic tectonic setting is still controversial in the southern Altaids. Some studies have attributed it is post-orogenic and intracontinental setting (Han et al., 2014; Wang et al., 2016; Zhang et al., 2015); In contrast, many geologists have proposed that it was the far-distance effects of the northward subduction of the Paleo-Tethys (Zhang et al., 2015; Zhang et al., 2009; Zhu et al., 2012); Furthermore, some researchers suggest that multiple supra-subduction accretion to terminal closure of the Paleo-Asian Ocean (Mao et al., 2021; Windley et al., 2007; Xiao et al., 2018). The eastern Tianshan-Beishan orogen is an ideal region to address the final tectonic of the Altaids. To address this issue, systematic mapping, geochemical and geochronological studies are carried out on the Haluo ophiolitic mélange in the middle segment of the Kanguer accretionary complex in the eastern Tianshan and the Houhongquan ophiolitic mélange in Liuyuan accretionary complex in the southern Beishan orogen, respectively. The studies reveal that the Paleo-Asian Ocean closed during late Triassic in the eastern Tianshan to Beishan orogens, southern Altaids, NW China. The Haluo ophiolitic mélange consist of the blocks of gabbro, massive basalt, diabase dikes, chert and limestone that are embedded in the imbricated chlorite-phyllite schist and cleaved sandstone matrix, whereas the Houhongquan ophiolitic mélange are mainly composed of the gabbro, basalt and chert, and some blocks of cleaved sandstone. (1) The studies of the Haluo ophiolitic mélange determined that a basaltic fragment yields zircon U-Pb age of 257 Ma and owns normal-mid-ocean-ridge-basalt (N-MORB) geochemical signature; the other mafic fragments display N-MOR and supra-subduction zone (SSZ) types of oceanic lithosphere; the sandstone matrix display two different types of provenances, the first type in the northern part has maximum depositional ages ranging from 316 Ma to 234 Ma and the detrital zircon age patterns vary from a single peak to multiple peaks after ca. 244 Ma, and their zircon $\varepsilon Hf(t)$ values vary from uniquely high positive to some negative values; the second type in the southern part has maximum depositional ages of 271 Ma to 234 Ma and multiple-peak detrital zircon-age patterns, and positive to negative zircon $\varepsilon Hf(t)$ values. These data suggest the Kanguer Ocean / Northern Tianshan Ocean experienced double-sided subduction, the Dananhu intraoceanic arc and Japan-

type central Tianshan-Yamansu arc finally amalgamated timing after 234 Ma. (2) The studies of the Houhongquan ophiolitic mélange obtain the similar results that the mafic fragments are Permian (~ 286 Ma to 270 Ma) relics of N–MOR and SSZ types of oceanic lithosphere; the matrix samples yield the maximum depositional ages of 264 Ma to 222 Ma, also indicating that the youngest sandstones were tectonic emplaced in the Houhongquan ophiolitic mélange after ca. 222 Ma. Thus, complicated archipelago systems may have existed in eastern Tianshan-Beishan area during the Permian to early Triassic. Combining the previous regional data, we argue that the terminal amalgamation timing of the southern Altaids was probably during ca. 222 Ma to 217 Ma.

Abstract

The Paleozoic tectonic evolution of the Western Kunlun Orogen (WKO) plays an important role in deciphering the Tethyan tectonic evolution. The WKO, located along the northern periphery of the Tibetan plateau, extends over 1000 km from the Pamir syntaxis in the west to the Altyn–East Kunlun Orogen in the east. Occupying a key tectonic position between the Tarim block to the north and the Tethyan domain to the south, the WKO is thought to be an accretionary orogen, resulting from the subduction and closure of the Tethyan Ocean(s). The timing of the closure and tectonic evolution of the Proto- and Paleo-Tethys Oceans remain debated, with controversies persisting about the location and nature of tectonic boundaries, as well as the poorly understood active marginal and oceanic complexes and Precambrian basement within the WKO, which limits our understanding of its tectonic evolution from the Precambrian to the Paleozoic.

This study provides new geochemical and geochronological findings, complemented by Lu-Hf isotopic analysis, derived from an ophiolite complex in the eastern sector of the WKO. These insights shed light on the tectonic framework and source characteristics of the region. Based on these new data, combined with previous data, we propose a new tectonic model for the eastern section of the northern Western Kunlun Orogen, suggesting a continuous evolution process of multi-terrane subduction-accretion collage from the Early Ordovician to the Middle Devonian in the Paleo-Tethys Ocean, which evolved into an Andean-type active margin in the Early Permian, contributing to the substantial continental growth of the southern Tarim margin.

Andean-type orogenic plateau as a potential trigger for Permian aridification of North China in northeast Pangaea

Dongfang SONG[1]*, Institute of Geology and Geophysics, Chinese Academy of Sciences (dfsong@mail.iggcas.ac.cn)
Wenjiao Xiao[2], Institute of Geology and Geophysics, Chinese Academy of Sciences
Qigui Mao[3], Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

The relationship between Pangea assemblage and climate change during the late Paleozoic remains ambiguous. The Central Asian Orogenic Belt (CAOB), an accretionary orogen formed through closure of the Paleo-Asian Ocean (PAO), is significant for understanding the paleogeographic architecture and associated tectonic-climate interaction of northeast Pangea. The orogenic process of the southern CAOB and its role in Permian aridification of North China is highly controversial. We present new sedimentologic and provenance study of Permian-Early Triassic sediments and first estimate of crustal thickness of northern North China. The early-middle Permian coal-bearing sandstones/conglomerates gradually gave way to late Permian-Early Triassic fluvial redbeds. Sandstone compositions and detrital zircon U-Pb ages with pervasive negative εHf(t) values indicate that the Permian-Early Triassic sediments were sourced from Paleoproterozoic-Neoarchean (1600-2700 Ma) basement of the North China Block and associated late Paleozoic (260-410 Ma) continental arc, devoid of any input from the juvenile Altaid arcs. The Permian-Early Triassic sedimentation is interpreted as a retroarc foreland system due to southward subduction of the PAO prior to final collision between the Altaid arcs and North China. Crustal thickness estimated from whole-rock La/Yb yields an average value of 58 ± 11 km, which corresponds to a palaeoelevation of 3.8 ± 0.7 km, indicating the development of an orogenic plateau comparable to the Altiplano of Andes, which possibly blocked the moisture from the PAO. The Permian paleoclimate change as indicated by significant sedimentary facies shift from coal-bearing humid alluvial fan deposit to continental redbeds is therefore interpreted as a rain shadow effect due to the orographic barrier uplift of the northern margin of North China. Our study provides significant insights into the study of tectonic-climate interaction in ancient orogens.

Late Paleozoic and Triassic clastic rocks in the Changning-Menglian Belt: insights into paleogeography of the Paleo-Tethys in western Yunnan, China

Jianbin ZHENG[1]*, Institute of Geology, Chinese Academy of Geological Sciences (jianbinzheng_1990@126.com)
Xiaochi JIN[2], Institute of Geology, Chinese Academy of Geological Sciences
Hao HUANG[3], Institute of Geology and Geophysics, Chinese Academy of Sciences, China
Zhen YAN[4], Institute of Geology, Chinese Academy of Geological Sciences

Abstract

The Changning-Menglian Belt in western Yunnan, China, has been widely recognized as the remains of Paleo-Tethys in Southeast Asia. It extends north–south and divides the Simao Block of Cathaysia-affinity to the east and the Baoshan Block of Gondwana-affinity to the west. Many researchers considered it as the major Tethyan suture, representing a long-lived ocean from early Devonian to Late Triassic, based mainly on slices of Devonian-Triassic radiolarian-bearing cherts, some ophiolites and possible seamount limestones of Permo-Carboniferous age. Some researchers, on the other hand, have argued that this belt represents a passive continental margin, with a cryptic suture further east representing the now-vanished Tethys. We have been studying the late Paleozoic-Triassic clastic rocks in this belt, as a significant component of the Changning-Menglian belt, in order to investigate the structural patterns of this region and better understand its geological evolution. The identifiable clastic rock sequences within the belt are, respectively, the Lower Carboniferous Nan Duan Formation, the Late Devonian-Early Carboniferous Nanpihe Formation, and the Lower-Middle Triassic cherts with clastic interlayers.

Petrological and geochemical studies have identified two distinct types of rock sequences from the late Paleozoic clastic rocks: the early Carboniferous Nanduan Formation developed and the late Devonian-early Carboniferous Nanpihe Formation, developed in the east and west zone and of this belt respectively. Quartz sandstones of the Nanduan Formation preserved dominant age populations of ca. 950 Ma and ca. 550 Ma. Similar zircon age peaks are also shared by the early Paleozoic metasedimentary rock groups (the Ximeng, Mengtong and Lancang Groups) widely developed in this belt, and other Gondwana-derived blocks (e.g. Baoshan-Shan and Tengchong Blocks). These results let us consider that the Nanduan Formation and the Lancang, Ximeng and Mengtong Groups were deposited along the passive continental margin of Gondwana-derived blocks (most possibly the Baoshan Block). While detrital zircon age spectra of the lithic sandstones from the Nanpihe Formation show remarkable age clusters of ca. 435 Ma and ca. 950 Ma, which is similar to those sandstones from the Indochina-Simao Block. Namely, the Nanpihe Formation in the west zone of this belt is of Cathaysia origin. Taking all into consideration, it can be speculated that sometime in the Permian or Early Triassic, as the eastward subduction of the Paleo-Tethys progressed, the Nanpihe Formation was sheared off or collapsed from the overriding margin of the Simao Block and entered the accretionary wedge, which contained a significant amount of rock slices scraped off the subducting oceanic plate. During the closure of Paleo-Tethys in the Late Triassic, this formation and some other slices of the accretionary wedge were thrust

onto the east flank of the Baoshan Block.

Additionally, we have recently identified several new sequences of Early-Middle Triassic age, including clastic rocks and bedded cherts-clastic rocks. The petrological and sedimentological features indicate a sufficient detrital supply for these Triassic sequences. Specifically, these rocks suggest a continental margin environment during that time rather than a pelagic oceanic environment.

Zircon U-Pb age of an intermediate dike intruding into the Selenge igneous rock complex at the Jargalant Village, Northern Mongolia

Sukhbaatar PUREVDULAM[1]*, School of Environmental Studies, Nagoya University
(puujee.0@yahoo.com)

Abstract

Abstract
In northern Mongolia, the volcanic/plutonic rocks of the Permian-Triassic Selenge igneous rock complex (SIC) are widely exposed and its intruded by many intermediate dikes with clear chilled margins, in some places. Numerous studies have examined magmatism in the SIC, but little attention has been given to the intermediate dikes within it. Umeda et al. (2022) and others revealed that the SIC is a product of large-scale adakitic magmatism caused by the melting of subducted oceanic slab at ca. 250 Ma. They also mentioned that the intermediate dikes which have almost the same geochemical features with the SIC the evidence that the slab-melt-origin adakitic magmatism lasted after ca. 250 Ma. Therefore, clarifying the age of the dikes is necessary to confirm the span of the adakitic magmatism, i.e. magmatic history of the ancient volcanic arc along the “Siberian continent”. This study describes a zircon U-Pb age of the intermediate dike in the Jargalant area, northern Mongolia, and discusses the span of the adakitic magmatism along the “Siberian continent”.

Three samples of the comparatively coarse intermediate dike were examined. The zircons, colorless with about 200μm in the major axis, generally show clear oscillatory zoning in the cathodoluminescence image. A total of 17 grains (36-spots) were examined and the weighted mean age is 211 ± 5 Ma and MSWD is 2.9. Their Th/U ratio is from 0.61–1.27. Clear oscillatory zoning in the CL image evidences less alteration for the dated zircons. Furthermore, Th/U ratio of the dated zircons suggests their magmatic origin (e.g. Hartmann et al., 2000). Therefore, it is quite likely that the zircon U-Pb age of 211 ± 5 Ma from the intermediate dike points the age of its igneous activity.

Now, the age of the dikes intruding into the SIC is ca. 210 Ma was suggested by this study. That is, taking together with the geochemical data Umeda et al. (2022), the slab-melt-origin adakitic magmatism had occurred under the Siberian continental margin at Late Triassic. Umeda et al. (2022) pointed out the geochemical homogeneity of the 250 Ma SIC and dikes with inference that the adakitic magmatism had lasted after 250 Ma till the time of the dikes. Given that their view is correct, adakitic magmatism would have lasted from 250 Ma to 210 Ma for 40 m.y. Is this reasonable?

It is suggested that oblique subduction and slab-tearing along a L-shaped trench cause the slab-melt-origin adakitic magmatism in the Aleutian–Kamchatka region (Yogodzinski et al., 2001). It is assumed that the oceanic plate of the Mongol-Okostk ocean had subducted beneath the Siberian continental margin along a L-shaped trench in the Permian–Triassic time, similarly to the Aleutian–Kamchatka arc (Pan Zhao et al., 2023). Therefore, it might be possible to consider that

the "slab-melt-origin adakitic magmatism for 40 m.y." would be attributed to the long-lived L-shaped trench system and slab-tearing.

The geochemical signature of the mafic rocks in the accretionary complexes of the western Khangai-Daur belt, Central Asian Orogenic belt, central Mongolia

BAYART NADMID[1]*, Department of Earth and Environmental Sciences, Nagoya University, Japan (n.bayart@yahoo.com)

Abstract

The geochemistry of accreted oceanic mafic rocks is crucial for understanding volcanic activity and the evolution of ancient oceanic plates. Within the western Khangai-Daur belt, in central Mongolia, Late Paleozoic accretionary complexes of the Tsetserleg, Kharhorin, and Ulaanbaatar terranes are situated between the Siberian continent and the South Mongolian block, formed through the subduction of previous oceanic plate of the Mongol-Okhotsk Ocean (MOO). Previous studies of the mafic rocks have primarily focused on specific local areas and did not comprehensively address the past oceanic plate of the MOO. This study aims to provide new geochemical data of the mafic rocks in the Khangai-Daur belt, and a comprehensive discussion of the nature of the MOO plate by integrating data together with the previous studies.

Whole-rock chemical composition of 21 samples from 4 localities within the Khangai-Daur belt (Uubulan, Ikh-Oortsog, the Takhilt area in the Ulaanbaatar terrane, and the Burd area in the Kharhorin terrane) was determined. The samples can be divided into the following three major types in their geochemical characteristics: Type-1 (Uubulan and Ikh-Oortsog areas), Type-2 (Takhilt area), and Type-3 (Burd area). The geochemical nature of the mafic rocks, enriched in large ion lithophile elements and light rare-earth elements compared with high field-strength elements and heavy rare earth elements, suggest that they are alkaline basalts. The TiO2 vs. Zr/(P2O5*10000) diagram also supports that the samples have an alkaline signature, but, they differ in their concentrations of incompatible elements: Type-1 is highly enriched in incompatible elements, while Type-3 is less enriched and shows a gently reducing trend in the spidergrams and REE patterns, and the Type-2 is the moderate between them. Despite these differences, all three types show an affinity with Ocean Island Basalt (OIB) in TiO2/Yb vs. Nb/Yb diagram.

As a result of comparison to the previous studies, the following insights were led. In the Ulaanbaatar terrane, the Type-1 and Type-2 are included, and, the mafic rocks in the Tsetserleg terranes display Type-2 and Type-3. While the Type-3 mafic rock was recognized in the Kharhorin. In contrast, mid-ocean ridge basalt (MORB) (Type-4) is reported only in Tsetserleg terranes. Therefore, compositions in the (La/Sm)n vs. (Gd/Yb)n plot along the melting curve of garnet lherzolite with a primitive mantle composition, indicating a degree of partial melting ranging from 1–3% (Type-1), 3–5% (Type-2), and 10%–20% (Type-3 and 4), respectively. These observations suggest that varying magma sources and degrees of partial melting at different depths contribute to the production of alkaline OIB and MORB within the MOO plate.

Abstract

The Neo-Tethys is one of the most extensive subduction architectures on Earth with large-scale oceanic deep subduction occurred in the Jurassic-Cretaceous. Yet, when it lasted into Cenozoic and how the subduction interface behaved remain unclear due to no records of younger subduction milestones (i.e., blueschists). Herein, we present a comprehensive study for representative blueschist-facies rocks from Zeyarat metamorphic complex to uncover the time frame and metamorphic process affecting Neo-Tethys suture zone in the Makran area in Iran. Our new bulk-rock geochemical data show that Zeyarat Bs-facies metavolcanics are typical of oceanic protolith from depleted mantle. A counter-clockwise P-T trajectory, from burial along a typical warm subduction gradient (~15 °C/km) with moderate heating to peak temperature condition of 0.74-0.88 GPa, 510-550 ˚C at amphibolite-facies, subsequently reaching Bs-facies condition of 1.12-1.28 GPa, 370-400 ˚C with slightly cooling, is retrieved. Efforts are made to correlate the ages of dated amphibole, titanite, and zircon with their respective metamorphic and igneous origins. In detail, titanite U-Pb ages of 74.9 ± 1.80 Ma and metamorphic zircon rim U-Pb ages of 80.0 ± 5.84 Ma could constrain the timing of early-stage peak burial slightly after amphibolite-facies peak temperature metamorphism. The igneous core domain of zircon displays Concordia age of 117 ± 4.70 Ma, coinciding with comparable age of 118 ± 2.00 Ma obtained for igneous zircon and 117 ± 0.40 Ma age of hydrothermal zircon, echoing with the origin from oceanic protolith and seafloor hydrothermal setting during the subduction of Neo-tethys ocean. By comparison, step-heating 40Ar-39Ar radiometric dating of amphibole, with predominantly glaucophane composition, yields consistent weighted plateau ages at 49.7 ± 0.60, 46.1 ± 0.30, and 46.4 ± 0.60 Ma, disclosing, for the first time, a Neo-Tethys related Eocene Bs-facies metamorphism in the territory of Iran. An updated model for the still active Neo-Tethys subduction in the Makran area is thus proposed, highlighting the decrease of convergence rate with scarce reports of Eocene localized viscous coupling, between the plate interface, which would facilitate the rescue of LT-HP rocks in Zeyarat

(Makran, Iran), Tso Morari (India) and Kaghan Valley (Pakistan), compared with the large-scale Late Cretaceous interplate mechanical coupling across thousands of kilometers that affected the whole Neo-Tethys subduction zone beneath Eurasia.

SEDIMENTARY RECORD OF A BASIN MARGINAL TO THE TETHYS OCEAN: THE CERGOWA BEDS (OUTER CARPATHIANS; OLIGOCENE)

Marek WENDORFF[1]*, AGH University of Krakow (wendorff@agh.edu.pl)
Joanna PSZONKA[2], Polish Academy of Sciences, Mineral and Energy Economy Research Institute, Krakow, Poland
Paweł GODLEWSKI[3], AGH University of Kraków, Poland

Abstract

The eustatic sea level fall in the Eocene-Oligocene, crucial for the Paratethys isolation from the Tethys Ocean, was caused by global climate cooling. This change influenced the Carpathian basins located marginally to the ocean, resulting in reduced circulation and anoxic conditions recorded in the Outer/Flysch Carpathians by the Menilite Formation (Oligocene) characterised by dark shales. The Menilite Fm. contains arenaceous lenticular lithosome of the Cergowa Beds composed of sandstones and subordinate sandstone-mudstone associations deposited by sediment gravity-flows during two nannoplankton zones NP 23 and NP24. The older part of the Cergowa Beds, which originated during the NP23 zone, was deposited by mainly dense, sandy sediment gravity flows, including high-density turbidity currents. The associated nannoplankton species indicate brackish water conditions, which reflect a significant freshwater influx into the basin confined and isolated from the Tethys Ocean. A direct connection between the basin and the terrestrial source via a fluvial system and probably a shelf-edge delta is suggested by the abundance of coalified plant matter. Basin shallowing and the resulting isolation were caused by tectonic uplift during the Alpine orogenesis and eustatic sea-level fall induced by global cooling. The succeeding strata and nannoplankton representing the NP24 zone indicate an open sea environment and deposition by low-density turbidites declining with time and finally returning to the anoxic mudstone facies typical for the Menilite Fm. In general, continuing global cooling and eustatic sea-level fall did not prevent the Cergowa Basin from deepening. This relation shows that the local subsidence rate in the Cergowa Basin must have exceeded the sediment supply, and accumulation, rate. In effect, the marginal position of the Cergowa Basin relative to the Tethys Ocean and the Oligocene climate resulted in the stratigraphic record influenced by: (i) oscillations of coccolithophorid productivity reflecting the CCD fluctuations and recorded by the pelagic laminated Tylawa Limestone; (ii) local slope instability recorded by slumps and hybrid flows recording synsedimentary tectonic deformations of the sea bottom; (iii) salinity changes between open marine and restricted brackish basin; (iv) variations in subsidence and sediment supply rates.

Abstract

Describing the detailed propagation sequences of thrust imbrication is crucial for understanding orogenic architecture and orogenesis. In this study, we investigate the pressure-temperature-timing and deformation characteristics of a suite of metamorphic rocks within the Main Central Thrust Zone (MCTZ) in the eastern Nepalese Himalaya. Our data reveal a southwestward shearing pattern of the major thrusts within the MCTZ, following a piggyback-style propagation since approximately 17 Ma. At around 12.8 Ma, a significant event occurred when a thrust sheet moved southeastward over an allochthonous mica-schist in the hinterland via an out-of-sequence thrust (OOST), coinciding with the accretion of the Lesser Himalaya to the MCTZ. Subsequently, another phase of piggyback-style thrust propagation occurred until about 10.4 Ma. Notably, this OOST differs from an earlier identified OOST, the High Himalayan Thrust, suggesting the presence of at least two distinct OOST events within the metamorphic core of the Himalaya. The younger OOST is associated with a structural shift from northeast to northwest and appears to have occurred nearly simultaneously with changes in the velocity and rate of rotation of the Indian plate at around 13 Ma. This synchronization implies that the OOSTs responded to the anticlockwise rotation of the Indian plate, influencing and reconciling the regional geometric evolution.

Vandana Prasad[4], Birbal Sahni Institute of Palaeosciences, 53 University Road, Lucknow 226007, India

Abstract

The Cretaceous was the most recent, warmest period in the Phanerozoic Era. It was characterized by more elevated atmospheric CO2 levels and significantly higher global sea levels than today. The IGCP 679 project (Cretaceous Earth Dynamics and Climate in Asia) is based on the Earth system sciences to reveal the Cretaceous 'Greenhouse' Earth's oceanic and terrestrial climates and environmental conditions and their evolution, leading to an in-depth understanding of the existing characteristics of rapid climate and environmental changes and global warming. This project explores the processes and mechanisms of the rapid change in climate and environment under greenhouse conditions during the Cretaceous and the evolutionary responses of biodiversity on land and in the oceans of the Asian continent. The main goals of IGCP 679 will address: (1) high-resolution Cretaceous geological records of sea and land facies in Asia; (2) climate and environment; (3) the nature of linkages between major geological events and rapid climate and environmental changes, to understand biodiversity evolution under greenhouse climate conditions. These results will provide scientific evidence for human response to contemporary global warming trends. The project has played an important role in promoting geoscience communication among Asian countries, including some countries outside Asia. In the last year, our project have made exciting research results and received good achievement on palaeontology, sedimentology, palaeoecology and palaeoclimate. The discovery of Masstrichtian dinosaur egg shells and teeth from the high latitude Far East Russia suggests special nesting strategies. The mercury contents and isotope ratios in marine and terrestrial archives across the Cretaceous/Paleocene boundary suggest the end-Cretaceous mass extinction was a complex catastrophe caused by the Deccan volcanism driving climate fluctuations and oceanic acidification, and perhaps exacerbated by the Chicxulub impact.

Development of a new silicate weathering index (RW) and its application to the Early Cretaceous strata distributed in East Asia

Tenichi CHO[1]*, Waseda University (tianct@fuji.waseda.jp)
Tohru OHTA[2], Waseda University
Gang LI[3], Nanjing Institute of Geology and Palaeontology

Abstract

Quantification of past weathering intensity is crucial for understanding paleoclimate changes. Given that the chemical composition of sediments/ sedimentary rocks reflects the weathering environment in which they were generated, this can provide insights into the intensity and style of weathering in the past. Weathering indices calculated from the whole-rock geochemical compositions of sedimentary rocks are widely used, however, these indices have limitations. For example, the conventional indices like CIA, WIP, and W index can only be applied to deposits consisting mainly of silicates, with low concentrations of materials like biogenic calcite. To develop a weathering index applicable to sedimentary rocks formed under various source rocks and environmental conditions, we used multivariate statistics (Independent Component Analysis) to analyze a dataset consisting of igneous rocks and their weathering profiles. The chemical variations of the igneous rocks and weathering trends were independently extracted from the dataset, and a new weathering index (the robust weathering index; RW) was proposed. The performance of the RW index is assessed using modern sediments. The RW index shows robust results even for sediments containing a large amount of non-silicate materials, enabling the comparison of weathering intensity across a wide range of sedimentary rocks.

We applied the RW index to the mudstone of the Lower Cretaceous terrestrial strata in southeast Asia. The studied sites include the Gobi area in Mongolia, the Junggar basin in Western China, Heilongjiang and Liaoning Provinces in NE China, Shangdong Province in Eastern China, Sichuan Province in SW China, Iwate Prefecture in Northern Japan, Banhang area in NE Vietnam. The RW index showed a tendency to increase as latitude decreases from mid-latitude to low-latitude areas. In addition, the RW index showed higher values along the coastal areas and lower values in inland areas. This distribution pattern of the RW index reveals a more temperate and humid paleoclimate condition in low-latitude area and an arid paleoclimate condition in inland areas. This paleoclimate interpretation is obviously consistent with the geographical distribution of each site and confirm that the RW index is useful in terms of paleoclimate reconstructions. It is expected that an accumulation of more data at various points will enable a detailed spatial-temporal reconstruction of paleoclimate in Cretaceous Asia, and further chronostratigraphic studies and geochemical analyses are therefore essential.

[Keynote] A synthesis of provenance studies of the Cretaceous Gyeongsang Basin, SE Korea and its tectonic implications for active continental margin in East Asia

Yong Il LEE[1]*, Seoul National University (lee2602@snu.ac.kr)

Abstract

In the middle to late Mesozoic period, the Korean Peninsula was in an active continental margin with an accretionary complex developed in the direction of trench to the southeast. The Cretaceous Gyeongsang Basin is the largest nonmarine basin distributed in the southeastern part of the Korean Peninsula. The sedimentary succession of the Gyeongsang Basin is subdivided into the Sindong and Hayang groups with decreasing age, which are unconformably overlain by the Yucheon Group which is mainly composed of intermediate to acidic volcanic rocks that make up a volcanic arc ('Yucheon Arc'). This basin is considered a transtensional or extensional basin formed by oblique subduction of the Paleo-Pacific (Izanagi) Plate or Izanagi slab rollback. Because the Gyeongsang Basin developed geographically behind the Japanese Arc in the Cretaceous, and the Yucheon Arc was considered an extension of the Japanese Arc, the Gyeongsang Basin has been considered to be a back-arc basin, even though sedimentation within the basin occurred before the development of the Japanese Arc and Yucheon Arc. Here, the results of provenance studies of clastic/volcanogenic sediments in the early−middle depositional phases (the Sindong and Hayang groups) are synthesized to reinterpret the tectonic setting and basin formation mechanism of the Gyeongsang Basin. The sediments were mostly derived from western and northwestern sources (the Yeongnam Massif), which currently do not contain records of Early Cretaceous arc magmatism. The modal and geochemical compositions of these sediments and their detrital zircon U−Pb geochronology indicate that these sediments originated from arc-related crystalline basement rocks of the Yeongnam Massif with a record of arc magmatism from the Early Cretaceous Period (143−100 Ma). Additionally, the Sindong Group contains detrital chromian spinel grains derived from forearc peridotites or their equivalents, and the Hayang Group contains radiolaria-bearing chert pebbles derived from the Jurassic accretionary complex at several stratigraphic levels. Thus, the Gyeongsang Basin is proposed to be a forearc basin formed between the Yeongnam Massif (then arc) and the Jurassic accretionary complex on the seaside, and the basin may have been formed by extensional stresses related to the subduction of an oceanic plateau during the Early Cretaceous.

Interpretations from detrital zircon geochronology of Lesser Himalaya strata, Nepal, regarding the Paleozoic-Mesozoic dispersal of Gondwana

Upendra BARAL[1]*, Institute of Fundamental Research and Studies (upendrabaral@gmail.com)
Ding Lin[2], State Key Laboratory of Tibetan Plateau Earth System Science, Resources and Environment, Institute of Tibetan Plateau Research, Chinese Academy of Sciences

Abstract

The study of the breakup of Gondwana to the India-Asia collision is crucial for the study of plate tectonics. Detrital zircon U-Pb geochronology has quickly developed into an effective method for retracing the processes of supercontinent construction and dispersal. The ages of detrital zircon from the Gondwana (Kakaha Diamictite, Carboniferous-Permian, and Jurassic-Cretaceous SaptKoshi Formation) and post-Gondwana (Tamrang Formation, Miocene, and Lesser Himalaya, eastern Nepal) sequences give some insightful information on it. The zircon ages from the Carboniferous-Permian sequence peak at 544 Ma, 890 Ma, 1178 Ma, and 1752 Ma. In addition to this, there is a peak of ~123 Ma in the Jurassic–Cretaceous sequence. The Miocene strata yield the peaks at 526 Ma, 987 Ma, and 1740 Ma. By contrasting these recently discovered ages with those of neighboring places, the present study can verify that the Indian continent remained connected to Gondwana during the Carboniferous-Permian period. The Tethys Himalaya and the Kokaha Diamictite have similar U-Pb age dispersals which raises the hypothesis that this unit was recycled or shared a similar genesis with the Tethys Himalaya. Magmatism associated with the Triassic–Jurassic rift along the Indian continental margin provides evidence that the Indian plate rifted from Gondwana and migrated northward throughout the early Mesozoic. Surprisingly, the Rajmahal Basalt contributed significantly to the Jurassic–Cretaceous sequence's deposition. Furthermore, a significant number of zircons from the Miocene sequence bear a striking resemblance to those from the Greater Himalaya, suggesting that the latter may have previously undergone uplift.

A new Early Cretaceous bird shed new light on the evolution of avian cranial kinesis.

MIN WANG[1]*, Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Sciences (wangmin@ivpp.ac.cn)

Abstract

Cranial kinesis, referring the independent movements and flexibility of various parts of the skull, is an evolutionary innovation found in living vertebrates only in some squamates and crown birds, and considered to be a major factor underpinning much of the enormous phenotypical and ecological diversity of extant birds. Compared to the postcranium, our understanding of the evolutionary assemblage of the characteristic modern bird skull has been hampered by sparse fossil records of early cranial materials. Consequently, little is known about how the bulky and akinetic dinosaurian skull became transformed into the delicate, kinetic, and functionally diverse extant bird skull. Here we present digital three-dimensional reconstruction of the entire skull of the Early Cretaceous enantiornithine Yuanchuavis kompsosoura, including poorly known elements among early diverging birds but are central to deciphering the evolutionary pathways of modern avian cranial kinesis. Our reconstruction shows evolutionary and functional conservation of the temporal and palatal regions by retaining the ancestral theropod dinosaurian configuration within the skull of this otherwise derived and volant bird. Geometric morphometric analysis of the palatine suggests that loss of the jugal process represents the first step in the structural modifications of this element leading to the crown avialan condition. The mixture of plesiomorphic temporal and palatal regions and derived facial anatomies captured in this single enantiornithine skull vividly demonstrates how the avian cranium has been shaped deeply by evolutionary mosaicism—a hypothesis proposed by studies involving crown birds but still awaiting paleontological evidence.

The sedimentological characteristics of the intermontane desert system in the Jurong Basin, South China and its relationship with the Late Cretaceous hot climate

Shuo CAO[1]*, China University of Geosciences, Beijing (caoshuo@cugb.edu.cn)

Abstract

As a typical greenhouse period, the Late Cretaceous was characterized by an extremely warm and arid climate. In this period, intermontane deserts were widely distributed in South China, which can be used to inform the evolution of the palaeogeography and palaeo-wind patterns during the hot climate of the Late Cretaceous. The Jurong Basin is located at the eastern margin of South China and close to the palaeo-Pacific Ocean; it has typical aeolian deposits but is hitherto less studied. In this study, four sedimentary facies (aeolian dune, dry/damp/wet interdune, sandsheet, and desert lake facies) and three forms of aeolian dunes (simple, compound, and complex) are identified in the Upper Cretaceous Chishan Formation, confirming the development of an intermontane desert in the Jurong Basin. The dynamic evolution models show that the intermontane desert transitioned from a lacustrine-dominated to an aeolian-dominated system, which indicates a gradual drying trend. We suggest that the development of the Chishan intermontane desert was controlled by the Late Cretaceous greenhouse climate, the accelerated aridification of the subtropical high, and the rainshadow effect of the coastal mountains. Palaeowind directions in the Chishan desert show westerlies and possible palaeo-monsoon wind patterns. The input of palaeo-monsoon moisture led to the development of desert lake and damp/wet interdune deposits in the Chishan desert, which indicates that the Jurong Basin might have been on the windward side of the coastal mountains during the Late Cretaceous. Our study extends the eastern boundary of the South China intermontane desert system during the Late Cretaceous.

Vegetation response against environmental change during the Oceanic Anoxic Event 2 recorded by terrestrial plant biomarkers in sediments from the Tomamae (Hokkaido, Japan)

Masashi A. IKEDA[1]*, Faculty of Geosciences and civil Engineering, Institute of Science and Engineering, Kanazawa University (ma_ikeda@sci.hokudai.ac.jp)
Ken SAWADA[2], Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University
Takuto ANDO[3], Graduate School of International Resource Sciences, Akita University
Hideto NAKAMURA[4], Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University
Reishi TAKASHIMA[5], The Center for Academic Resources and Archives, Tohoku University Museum
Hiroshi NISHI[6], Institute of Dinosaur Research, Fukui Prefectural University

Abstract

The Cretaceous was one of the warmest periods in the Phanerozoic eon. Especially in the mid-Cretaceous, the Oceanic Anoxic Events (OAEs) occurred several times and had a significant impact on marine and terrestrial ecosystems. Although OAE2, which occurred across the Cenomanian/Turonian Boundary (CTB), was the most severe of the OAEs and was a global event, previous studies suggest that the impact on terrestrial ecosystems may have varied from region to region. In the present study, we analyzed biomarkers of terrestrial plants in the sediments deposited across the CTB from northern Hokkaido, Japan, to reconstruct paleovegetation changes and to evaluate for the plant paleoecology during the environmental disturbance event.

We analyzed sediments across the CTB in the Saku Formation, Yezo Group, collected from the Omagari-zawa sections of the Tomamae area, northern Hokkaido, Japan. The sediments used correspond to the OAE2 intervals (1st build-up, Trough, 2nd build-up, Plateau, and Recovery phases), determined by δ13C stratigraphy. For the biomarker analysis, the extractions of crashed sediments were fractionated using a silica-gel column and analyzed by GC-MS.

The higher plant parameter (HPP), which indicates the expansion of conifer vegetation, varied considerably during the environmental disturbance phases (1st to 2nd build-up phases) and was synchronous with the δ13C curve, suggesting that conifer vegetations were strongly affected by climate change due to strong perturbations in the carbon cycle at the study area. On the other hand, the compositions of higher plant-derived terpenoids differed significantly between the 1st and 2nd build-up phases. In the 1st build-up, the triterpenoids (angiosperm origin)/diterpenoids (gymnosperm origin) ratio (ar-AGI) varied wildly, suggesting that conifers expanded after the temporary expansion of angiosperms. In contrast, the predominance of sesquiterpenoids relative to diterpenoids and triterpenoids in the 2nd build-up suggested a temporary decline of seed plants (gymnosperms and angiosperms) among terrestrial plants followed by the expansion of coniferous vegetation. Vegetation response in each phase might be depended on the extent of environmental disturbances in the study area. These can help to understand the impact of the OAE2 period on the

terrestrial ecosystems of the eastern margin of the Asian continent.

Stratigraphic, sedimentary and basin evolution and its chronological constraints on the transition from Yanliao biota to Jehol biota during the Late Meosozoic in North China

Yongqing LIU[1]*, Institute of Geology, CAGS (liu_cags@126.com)
Hongwei Kuang[2], Institute of Geology, CAGS
Nan Peng[3], Institute of Geology, CAGS
Yuchong Wang[4], Institute of Geology, CAGS
Xiaoshuai Chen[5], Institute of Geology, CAGS

Abstract

1. During the transition from Yanliao biota to Jehol biota in Yanshan of the North China, depositional succession from the Jiulongshan and Tiaojishan formations of the Late Jurassic, Tuchengzi to Zhangjiakou formations of Late Jurassic to Early Cretaceous and Yixian Formation of the Early Cretaceous were deposited. In the same time, significant migration and evolution of sedimentary basins took place in both time and space, that is, during the Yanliao biota period, the depocenters of Jiulongshan and Tiaojishan formations were in the eastern region of Yanshan, Tuchengzi Formation to Zhangjiakou Formation were in the northwestern Hebei region of the middle-western region of Yanshan, and Yixian Formation migrated back to the eastern Yanshan region.
2. The sedimentary sequence within the basin of the Tuchengzi Formation can be divided into five members, exhibiting the most complete development in Xuanhua and Shangyi regions in the western Yanshan and northwestern Hebei. Conversely, in northern Hebei and western Liaoning, only the third and fourth members of the same Tuchengzi Formation are present, while the fifth member is confined to Chaoyang and Beipiao, which further reflects the basin's patterns and the migration of its depocenter.
3. The Zhangjiakou Formation can be divided into the lower member aged ~145-140Ma and the upper member aged ~139-130Ma. The former and the Tuchengzi Formation and the latter and the Dabeigou Formation all show obvious depositional facies variation relationship. At the same time, the acidic volcanics of Zhangjiakou Formation are present at the end of the 3rd member (~ 145Ma) of Tuchengzi Formation in western northern Hebei, and (~145Ma) regional thick rhyolite breccia tuff or volcanics developed at the top and bottom of the 3rd member and the 4th member, followed by (~145-140Ma) rhyolites and thick tuffaceous conglomerate rhythm. It continued to develop (~139-135Ma) and expand to the eastern part of northern Hebei and (~130Ma) western Liaoning. The tuffaceous conglomerate association on the bottom of the 4th member of Tuchengzi Formation may indicate a larger scale and range of extension and basin development across the North China.
4. The 3rd member of Tuchengzi Formation (~145Ma) represents an isochronous regional period or horizon marked by the presence of dinosaurs, birds, and other vertebrates, predominantly in the form of footprints. The assemblages of flora and fauna that show differences between Yanliao biota and Jeohe biota, the 3rd to 5th member of Tuchengzi Formation and Zhangjiakou/Dabeigou

Formation are characterized by dinosaurs, and birds (mainly footprints) in the 4th member of Tuchengzi Formation (~145Ma) and fly and fish fossils in Dabeigou Formation. It is believed that the Jeohe biota started from the upper part of the 3rd member of Tuchengzi Formation during the Jurassic/Cretaceous transition (from the end of Late Jurassic to the beginning of the Early Cretaceous) from ~150-145Ma.

5. More importantly, both the Yanliao and the Jehol biotas and their transitional ecological environments show close links with volcanism, and in particular, the three different ecological environments have extremely significant specific burial mechanisms related to volcanism.

This research was founded by NSFC (42288201,41688103,41672111).

Cretaceous stratigraphy, paleogeography and major geological events in eastern Neotethys

Dangpeng XI[1]*, China University of Geosciences (Beijing) (xdp1121@163.com)

Abstract

The Cretaceous period was important for understanding the evolution of the Neotethys. The Cretaceous stratigraphy, paleogeography, and major geological events of the eastern Neotethys are carried out in this study, to establish a new stratigraphic framework, recover the paleogeography of different periods, and explore the major geological events. The Cretaceous stratigraphy of the Qinghai-Tibetan Plateau and its surroundings is mainly marine, with a small amount of interbedded marine and terrestrial deposits. The Indus-Yarlung Tsangpo suture zone developed deep-sea sediments. To the south, the Tethys Himalayas and Indus Basin developed shallow to semi-deep to deep-sea sediments, whereas to the north, the Xigazê and Ladakh forearc basin developed marine sediments; the Lhasa Massif, Karakorum Massif, western Tarim Basin, and West Burma developed shallow marine, interbedded marine-terrestrial, and terrestrial deposits; the Qiangtang Basin and other areas are dominated by terrestrial sediments. Based on multiple stratigraphic divisions and correlations of the lithostratigraphy, biostratigraphy, geochronology, and isotope stratigraphy, a comprehensive stratigraphic framework for the Cretaceous of the eastern Neotethys was proposed. The Cretaceous paleogeographic evolution of the eastern Neotethys can be divided into three phases: 1) gradual breakup of the Indian Plate and the Australia-Antarctica continent, as well as the early collision phase of the Lhasa-Qiangtang Massif (145–125 Ma); 2) northward drift of the Indian Plate and the late collision phase of the Lhasa-Qiangtang Massif (125–100 Ma); 3) rapid northward drift of the Indian Plate, formation of the Tarim-Karakorum Bay and early uplift of the Gangdise Mountains (100–66 Ma). With the northward drift of the Indian Plate and subduction of the Neotethys, the eastern Neotethys experienced a series of major geological events, such as the Great Igneous Province, oceanic anoxia (OAE), and extinction event.

Abstract

The Lower Cretaceous vegetation changes during the Apt-Albian, their climatic and environmental alteration are poorly studied in Mongolia. In this study, large amount of work done on spore pollen changes in the plant community structure are reconstructed based on spore pollen records and geochemical analyses of the Khovil coal deposit, Choir-Nyalga basin of the Central Mongolia.

Palynological data, 30 of the 18 samples contain rich palynological fossils providing important information on paleovegetation, paleolandscape and paleoclimates.

A total of 150 palynomorph consisting of spores and pollen of *pteridophytes*, *bryophytes* and *coniferous* pollen grains, and very rare angiosperm pollen grains were recovered in the present study.

As a result of geochemical analysis of major oxides, SiO2 has the highest content with 50.58-63.38%. Following this Al2O3 (1.55-21.63%), K2O (0.2-4.38%) and TFe2O3 (total iron) (1.82-7.52%) are the second most abundant oxides. The rest of the oxides (MgO, Na2O, P2 O5, MnO, CaO and TiO2) have concentration of less than 3.01%. The Al/Si ratio was between 0.16-0.50, SiO2 is related with quartz. The chemical weathering parameter CIA varies 31.13-86.14, with an average of 68.56, showing intermediate chemical weathering. Also, the Zr/Rb ratio 0.93 can be seen the hydrodynamic force was weak. Generally, V/Cr:0.98, U/Th: 0.97, δU:2.23 implies oxidation environment. All weathering parameters show oxidation environment during sedimentation indicating that the paleoclimate is warm and humid.

This palynological and geochemical data indicates that the at Khovil's coal bearing sediments vegetation change dynamics were controlled probably by the regional tectonic palaeolandscape development within a very equable, warm-temperate, and humid climate.

Diverse microbially induced sedimentary structures (MISS) from the Cretaceous deposits of Korea: occurrences and paleoenvironmental implication

Hyun Joo KIM[1]*, Pukyong National University (sunstay@pknu.ac.kr)
In Sung Paik[2], Pukyong National University

Abstract

Diverse microbially induced sedimentary structures (MISS) occur from the Cretaceous nonmarine deposits (Haman, Jindong, and Sayeonri formations) of South Korea. Their occurrences are documented and paleoenvironmental implications are interpreted preliminarily. These formations are composed of siliciclast-dominated lithofacies that were deposited in alluvial plain and lake margin to shallow lake. MISS from the formations include roll-up structure, reticulated surface, wrinkle structure, kinneyia structure, honeycomb-like texture, knobby texture, sieve-like surface, and chipped mat which are related to microbial mat growth and destruction. FE-SEM and EDS analysis of their thin sections and surfaces show microbial traces such as filamental and coccoidal organic matters and chipped microbial mats. MISS are observed on mudstone layers of interlaminated fine-grained sandstone to siltstone and mudstone and planar- to cross-laminated fine-grained sandstone to siltstone covered with mudstone layer. These lithofacies are interpreted to have been formed by unconfined flows in alluvial plain and lake margin under semi-arid paleoclimatic conditions with alternating wetting and drying intervals. Evaporite mineral casts and pedogenic carbonates suggesting the semi-arid condition are occasionally associated with the alluvial plain and the lake margin to shallow lake deposits. The occurrences of MISS in these deposits imply that microbial ecosystem was thriving in the evaporitic and stressed terrestrial environments under semi-arid climate during the Cretaceous in Korean Peninsula. The diverse occurrences of MISS from the Cretaceous deposits suggest that ancient MISS may occur throughout wide stratigraphic and paleoenvironmental ranges, in spite that most of MISS have been documented in Precambrian shallow marine and tidal flat deposits.

Mineral magnetic variations across an inland sea-way excursion around Late Maastrichian/Danian deposition of the Jhilmili intertrappean in the Deccan Volcanic Province, Mandla lobe, Madhya Pradesh, India.

Jyotibala SINGH[1]*, savitribai Phule Pune university (balajyotisingh@gmail.com)
S.J. Sangode[2], Savitribai Phule Pune university
Bandana Samant [3], RTMNU , GEOLOGY DEPARTMENT

Abstract

The Late Maastrichtian-Danian sedimentary sequences associated with Deccan large continental flood volcanism are commonly associated with fluviatile, lacustrine and pedogenic environments. The discovery of Danian zone-P1a planktic-foraminifera (during the time of rapid global sea level fall) from a thin-horizon of an otherwise entirely lacustrine-palustrine section at Jhilmili in the Central India, makes it a unique inland marine incursion record. The ~66 cm thick unit comprising foraminifera and benthic calcareous algae is suggestive of the brief inland seaway and record anomalous peak in magnetic coercivity (B(0)CR). Close interval Magnetic mineralogy and clay mineral study offer robust semiquantitative estimates on the paleoenvironmental conditions with humid to warm arid fluctuations. The largely variegated shale-silt-marl intervals are dominated by antiferromagnetic mineralogy with phases of goethite/hematite predominance that are quantified here using new mineral magnetic proxies based on IRM field cancellation technique, into various degrees of oxidative/hydrous conditions within the profile. The anomalous peak in coercivity precisely match with the P1 zone depicting extremely humid depositional environments marked by the production of goethite. On the other hand, the topmost ~50 cm sequence contain the SD-MD detrital/insitu ferrimagnets depicting the complete withdrawal of marine conditions and reducing lacustrine environments. The mineral magnetic based paleoenvironmental analogue developed for the Jhilmili section is further integrated with biostratigraphic information and the quantification is achieved that is useful for inter-site correlation of such intertrappean sections within Deccan province. The sections with and without marine excursions may be identified with great implications on the K/Pg boundary in Deccan intertrappeans.

Evaluation of the hinterland paleoweathering during the mid- to late-Cretaceous in Northwestern Kyusyu, Japan

Arisa NAKANO[1]*, Waseda University (risa.arisa@ruri.waseda.jp)
Niko TODA[2], Waseda University
Tenichi CHO[3], Waseda University
Tohru OHTA[4], Waseda University

Abstract

Cretaceous is characterized by high atmospheric CO2 levels and the consequent elevation in paleotemperature. Therefore, reconstruction of the paleoclimate during this period is important for understanding the Earth system under super-greenhouse condition. However, Cretaceous paleoclimate studies of continental margin basins in eastern Asia are scarce than that of inland basins.

The present contribution aims to reconstruct hinterland paleoweathering during the mid- to late Cretaceous in Kyusyu, which is located in western part of Japan as an example of paleoclimate information on the mid-latitude continental margin. Mudstone samples were collected from the mid- to late Cretaceous strata distributed in the Amakusa-Mifune district, Northwestern Kyusyu, which were mostly deposited in marine to fluvial environments. The whole rock chemical composition and clay mineral composition were obtained by XRF and XRD, respectively. The degree of continental weathering was investigated using the geochemical weathering indices (RW index, W index, and Rb/Sr ratio) and clay mineralogy.

Geochemical weathering indices show relatively low values from upper Albian to lower Cenomanian (the Eboshi Formation), and then increase from lower Cenomanian to middle Cenomanian (the Enokuchi Formation). These values reach maximum during the Cenomanian-Turonian interval (the Mifune Group) and then decrease. RW index maintain low values from Santonian to Coniacian (the lower Himenoura Group), though W index and Rb/Sr ratio show large fluctuation. This discrepancy may be due to non-silicate input (carbonate minerals), and it suggests that RW index is more robust when carbonate mineral contamination are present. The values of RW index and W index obtained from this study range from 25 to 47 and from 24 to 76 respectively. These values are comparable to the RW and W indices obtained from modern soils developed under temperate climates. (Smectite+Kaolinite)/Illite ratio also increases during Cenomanian-Turonian interval. These lines of evidence suggest that the mid-latitude area of the east Asian continental margin became warmer and/or more humid climate condition during the Cenomanian-Turonian interval, which is consistent with the extremely high global temperatures during the mid-Cretaceous.

Interpretation of Cretaceous geomorphology in eastern China based on palynological data

Suping LI[1]*, Institute of Geology, Chinese Academy of Geological Sciences (lisuping@live.com)
Tianquan QU[2], Institute of Geology, Chinese Academy of Geological Sciences

Abstract

The uplift and collapse of the coastal mountains in East China has been a highly concerned and controversial topic in the geoscience aspect in recent years. Compared to the studies of the uplift of Tibetan Plateau, researches on the geomorphic evolution of the coastal mountains are still lacking. The uplift and collapse process is still unclear. It is necessary to provide more research clues and new thoughts from different aspects to understand the transformation process of geomorphic pattern in East China from “High-East, Low-West” to “High-West, Low-East” during Mesozoic-Cenozoic. Pollen and spores have incomparable advantages in the study of paleoclimate and paleoenvironment. Over the last few decades, sporopollen data have been applied to reconstruct the paleoelevation, and some remarkable Neogene paleoelevation works have been published. However, few efforts have been made concerning the Mesozoic-Cenozoic eras especially the critical Cretaceous, the potential in paleoelevation reconstruction has not been deeply explored. Based on large numbers of sporopollen data in Cretaceous and early Paleogene, we found that there might be a high-altitude landform in northeast China during the early Early Cretaceous. Additionally, it is likely that coastal mountains existed in the Fujian and Zhejiang regions during the Early Cretaceous. In early Late Cretaceous, the range of coastal mountains in eastern China reached its maximum. From the late Late Cretaceous to early Paleocene, the mountains in eastern China gradually collapsed, and by the early Paleocene, the mountains probably disappeared. Although supporting evidences from other aspects still necessary, this work providing paleontological interpretations for the solution of this scientific question from a new perspective.
This work was supported by the National Natural Science Foundation of China (Grant No. 42372041) and the China Geological Survey (Grant No. DD20221646).

Stable carbon isotope stratigraphy of the Tetori Group, Upper Jurassic to Lower Cretaceous siliciclastic shallow-marine to non-marine succession in central Japan: application for non-marine regional correlation

Mayuko KAMIMURA[1]*, Graduate School of Natural Science and Technology, Kanazawa University (f6ogtoad@gmail.com)
Koichi Hoyanagi[2], Department of Geology Institute of Science Shinshu University
Takuto Ando[3], Graduate School of International Resource Sciences, Akita University
Takashi Hasegawa[4], Faculty of Geoscience and Civil Engineering Institute of Science and Engineering Kanazawa University

Abstract

The Tetori Group is an Upper Jurassic to Lower Cretaceous siliciclastic shallow-marine to non-marine successions in central Japan. Understanding terrestrial environmental transitions in the eastern margin of East Asia from the Tetori Group requires crucial studies of the regional correlation. However, the correlation of non-marine strata is challenging due to lateral lithological variations and a lack of reliable index fossils. Carbon isotope stratigraphy would contribute to solve this problem.

The study measured stable carbon isotope ratios of organic matter (δ^{13}Corg) and total organic carbon contents in bulk sediments from three sections: The Tamodani section was selected because of its good stratigraphic continuity, the Itoshirogawa section as a type section, and the Shokawa section as it provided chronological anchors. To minimize local effects, multiple samples were collected and treated from each single horizon in the Tamodani and Itoshirogawa sections. Rock-eval pyrolysis was performed in the Tamodani and Itoshirogawa sections to evaluate origins of organic matter. Additionally, maceral components were examined in the Shokawa section.

In the Tamodani and Itoshirogawa sections, kerogens were recognized as over matured and identified as Type III or IV. In the Shokawa section, kerogens were largely composed of vitrinite. Therefore, the organic matter in these sections is believed to have originated from terrestrial higher plants. As a result, the fluctuations of δ^{13}Corg in this study is unlikely to be associated with mixing rate of organic matters from different sources.

Maximum intra-horizontal difference of δ^{13}Corg of these sections were as large as 1.56‰. The average value of each horizon was bracketed in the ranges of 3.08‰ and 4.92‰ in the Tamodani and Itoshirogawa sections, respectively. As this variation is larger than that in a single horizon, time stratigraphic trend of these sections are interpreted to be significant. The δ^{13}Corg fluctuation curves were tentatively employed for regional correlation.

The δ^{13}Corg curves are also correlated with regional curves from previous studies based on some datums and two isotopic correlative horizons showing higher (-22 to -20‰) and lower (~-25‰) were recognized. This stratigraphically correlative δ^{13}Corg stratigraphy is compared with Tethyan δ^{13}C stratigraphy established with carbonate carbon. The two key horizons could be correlated

with global Aptian and Hauterivian $\delta^{13}C$ events, respectively. The ranges of $\delta^{13}C$ fluctuation in the Tetori Group and Tethyan carbonate are almost identical or that of the Tetori Group is a little larger. It strongly supports our idea that the $\delta^{13}C$ stratigraphy from the Tetori Group reflects global $\delta^{13}C$ fluctuations and available for global correlation.

These two isotopic key beds can provide important datums for the Tetori Group and the Tamodani section will play an important role as a regional reference section. To compare the Tetori Group with East Asian non-marine sequences, the application of $\delta^{13}Corg$ stratigraphy there with similar technique is eagerly awaited.

Camille FRANÇOIS[7], Royal Museum for Central Africa and Commission for the Geological Map of the World
Manuel PUBELLIER[8], CNRS, Ecole Normale Supérieure de Paris and Commission for the Geological Map of the World

Abstract

The South America Map of Orogens is part of the project IGCP–667 The World Map of Orogens supported by Unesco and the International Union of Geological Sciences (IUGS). It is led by the Commission for the Geological Map of the World (CGMW). This project aims to design a digital and global map for geological time layers and which shows the mountain ranges formed through the Earth's geological history. The map then constitutes a tool to visualize the evolution of continents and, therefore, the distribution of Earth resources, seismic hazards, and global change.

Orogens develop in convergent settings and, generally, involve two or more continental or oceanic plates or blocks. For their representation on the global map, four types of orogenic systems were defined: (i) Type I, ocean–continent convergence accommodated by subduction (e.g., Andean Cordillera); (ii) Type II, accretion/collision of crustal elements derived from subduction (island arc or back–arc basin), a microcontinent, an oceanic shelf, or a ridge (e.g., North American Cordillera); (iii) Type III, continental collision, often after subduction (e.g., Himalayas), and (iv) Type IV, shortening of an intracontinental sedimentary basin and continental crustal material (inverted rift) (e.g., Atlas Mountains).

The South American Map of Orogens corresponds to one of the continental maps that make up the global map. It was carried out based on the Geological Map of South America 2019 and filtering the Tectonic Map of South America 2016 by orogenic tectonic setting and geological time. Also, sourcebooks on South American geology and scientific papers were reviewed. Databases and different CGMW maps allowed for identifying deformation features (folding, faulting), regional metamorphism indicators (high and ultra–high pressure rocks and high to ultra–high temperature rocks), magmatism, ophiolites, and molassic basins. All indicators of orogenic events.

The South American map is presented in 11 layers showing the orogens identified for the Paleoproterozoic, Mesoproterozoic, Neoproterozoic, Cambrian–Ordovician–Silurian, Devonian–Carboniferous, Permian–Triassic, Jurassic, Cretaceous, Paleogene, and

Neogene–Quaternary. Because the beginning for modern–style plate tectonics and therefore orogens (according to the defined typology) at or following 2.5 Ga is considered, for the Archean only cratons are presented. For South America, the Trans–Amazonian, Sunsás, Putumayo, Brasiliano, Famatinian, Alleghanian, Gondwanide, and Andean orogens were represented, among others.

One of the great challenges for the construction of the map in South America was the overlapping of orogenies from the Ordovician to the present, since the most recent events have masked the features of previous deformation. Another limitation was the deficiency in the characterization and period of activity of lineaments, folds, and faults that can be used as indicators for the boundaries of orogenic events and, therefore, limits of the polygons on the map.

This map of South America, along with the rest of the continents, was built with an educational approach. It was designed as a geoscientific knowledge product that can be explained simply to non–specialized audiences. It is expected to be an input for other world maps. The goal is that it can then be presented in paleogeographic reconstructions using 3D tools.

Continental migration does not conflict with the gyroscope

ZHAINA YERZHANOVA[1]*, IT Company Prime Source (zhaina.yerzhanova@gmail.com)

Abstract

The geological evolution of the Earth's crust, like the lithosphere, begins upon a single and unique (?) continent Pangea or probably the second variant - from Gondwana in terms of the rotating planets dynamics. A giant continent was naturally originated according to the laws of gravitational forces that are not yet controlled at the South Pole or very close to it. The residual magnetic field indicates only the drift of the Earth's crust, and not the mutation of the magnetic poles. Different plates have minerals in the rocks with primary paleomagnetism, which allows often to determine the interval of stratigraphic correlation on different continents. The changes in the pole position, both on the magnetic axis and the axis of rotation, are the motion of continents that move north along a spiral path, if you carefully look at the global map of any scale of with the plotted geographic objects. It can be assumed that there was such a unique island northward of Iceland with slowed-down subsidence of the Earth's crust, for example, the Atlantis civilization. It can be assumed that there was such a unique island northward of Iceland, which has already been drowned to the depths of the Greenland Sea on the edge of the North Pole swirl. With fading of activity the number of volcanoes increases mainly in the oceans, which allows framing large blocks within the oceanic crust. It’s amazing that areas of the Arctic Ocean (14756 mln), the Antarctic (14110 mln km2) are equal, which emphasizes the gravitational balance of the rotating planet and the shift of active volcanism to the northern hemisphere, where the continents collide on subsidence in the North Pole swirl.

Palynological variability within the Permian (Changhsingian) Umm Irna Formation (Jordan): implications for biostratigraphy and fluid flow character in alluvial formations

Michael H Stephenson[1]*, Stephenson Geoscience Consulting Ltd (mikepalyno@me.com)
B Bomfleur[2], Münster University
H Kerp[3], Münster University
P Blomenkemper[4], Münster University
R Bäumer[5], Münster University
J Schneider[6], Technische Universität Bergakademie Freiberg
A Abu Hamad[7], University of Jordan
P Jardine[8], Münster University

Abstract

The Permian (Changhsingian) Umm Irna Formation in Jordan contains one of the world's foremost Palaeozoic plant fossil localities which has influenced our understanding of the origin and early evolution of plant groups that later rose to dominate the vegetation of the Mesozoic. The formation was deposited in a transitional fluvial regime characterized by stacked small-scale braided channels and by larger channels with deposition on point bars. Between these channel-influenced areas were floodplain interfluves that were characterised by low-energy sheetflood deposits, shallow lakes and ponds, and peaty mires. Floodplain sediments, where not waterlogged, are generally pedogenically altered red-beds with ferralitic palaeosols, indicating a fluctuating groundwater table and humid to semi-arid climate. The three-dimensional structure of facies changes in the Umm Irna Formation indicates a flood plain in continual change with shifting channels and local depositional environments through a probable several million-year period. The result is a complex pattern of arenaceous and argillaceous sediments in a non-layer cake form, where arenaceous rocks may have several forms including channel sandstones, point bar sandstones, and braided channels; and where argillaceous rocks occur in the form of coaly lenses reflecting local peat accumulation, or in the form of abandoned-channel and oxbow-lake fills and of stacked crevasse-splay deposits. Unusually for an arid, hot desert environment, the argillaceous sediments exposed in outcrop yield well for palynology. A major project involving more than 150 palynology samples collected from different kinds of argillaceous unit across the formation's outcrop over around 2 km2, reveal the variation within single argillaceous units, both laterally and vertically, and between argillaceous units in the same sedimentary complex at similar stratigraphic levels.

When combined with fossil plant data, the results have implications for the palynological study of alluvial sequences of Mesozoic and Palaeozoic age, and for understanding the ability to identify mudstone units via palynological fingerprinting. Such individual units are of great importance as baffles to fluid flow in reservoirs that might be used for oil and gas, low temperature geothermal, carbon capture and storage, and hydrogen storage, in alluvial successions.

Expression of the Prague Event (Lochkovian-Pragian boundary) in the Carnic Alps (Italy and Austria)

Carlo CORRADINI[1]*, Università di Trieste (ccorradini@units.it)
Maria Giovanna Corriga[2], Università di Trieste
Monica Pondrelli[3], IRSPS - Università D'Annunzio
Thomas James Suttner[4], Czech Geological Survey

Abstract

In the late Lochkovian a regression is documented in several areas of the world, followed by a transgression in the early Pragian. Connected with the eustatic variation, a minor extinction event occurred (“Prague Event”), affecting several fossil groups, a strong reduction of carbonate production and sedimentary facies changes. The Carnic Alps are a key area for studying this event, because Lower Devonian rocks are widely exposed, representing diverse sedimentary environments from shallow water to relatively deep shelf. Six formations were discriminated in the upper Lochkovian and Pragian. Several sections were measured along the Carnic Alps across the Lochkovian-Pragian boundary. In the shallower part of the basin, both the Polinik and the Seekopf fms span the boundary, but evident erosional surfaces are observable in the field at the Lochkovian-Pragian boundary; unfortunately, up to date, it was not possible to constrain chronostratigrafically the hiatus in the Polinik Fm. due to the missing of stratigraphically useful fossils. In correspondence of the Seekopf Fm., above the unconformity, at places the so-called megaclast horizon is present. In intermediate settings the Rauchkofel Fm. is uncorfomably followed by the Kellerwand Fm., and different parts of the upper Lochkovian and the lower Pragian are missing in the various sections. In the deeper parts of the basin the transition from the La Valute Fm. to the Findenig Fm. is slightly diachronous from the latest Lochkovian to the earliest Pragian; however, conodonts and tentaculites are rare in the marly boundary beds, preventing a precise chronostratigraphic calibration of these levels. At places, evidence of subaerial exposure at the formational boundary are documented. In general, the hiatus seems to be larger in the western part of the Carnic Alps, in correspondence with the shallower parts of the succession, suggesting a sea level drop in the uppermost part of the Lochkovian, followed by a transgression in the lower part of the Pragian.

Integrating geochemical and geochronological methods to improve geological mapping in Aus, Southern Namibia

Claudia MUTONGOLUME[1]*, Geological Survey of Namibia
(claudia.mutongolume@mme.gov.na)
Ewereth Muvangua[2], Geological Survey of Namibia

Abstract

Geochemical and geochronological analyses have been employed to discern and characterize the prevalent granitoid intrusions of the Aus area, southern Namibia. Aim of the project was to enhance the understanding of the tectonic setting and stratigraphy of this part of the Namaqua-Natal Metamorphic Province, which straddles southern Africa from the Atlantic to Indian coasts. The oldest rocks in the area consist of slivers of the Palaeoproterozoic Garub Group, comprising marble, calc-silicates, metapelites, garnet-biotite quartz gneisses, amphibolites, mafic granulites, and serpentinites extensively intruded by granitoids displaying variable degrees of deformation (e. g. Tsirub, Aus and Kubub orthogneisses). Geochemical analyses indicate that all granitoids within the area exhibit acidic characteristics, are strongly peraluminous, and products of shoshonitic and high-K calc-alkaline magma sourced from an A-type origin. The A-type granites resulted from crustal contamination during a phase of continental extension, and subsequently underwent compressional deformation. Chondrite-normalized spider diagrams depict negative anomalies in Ta, Nb, P, and Ti, alongside enrichments in Th and LREE, indicative of an arc environment origin. Plots correlating K2O with SiO2 exhibit considerable scatter, possibly attributable to the influence of crustal contamination. Three distinct geotectonic settings have been established: syn-collisional Granite (syn-COLG), Volcanic Arc Granites (VAG), and Within Plate Granites (WPG). The erratic plots observed in samples may be ascribed to hydrothermal alteration and/or varying degrees of fractionation within multiple flows, supporting a model of crustal fragment collision. Geochronological analyses give emplacement ages for the Tsirub augen gneiss and the Aus granite gneiss of 1110 ± 7 Ma and 1085 ± 36 Ma, respectively.

Key findings of the geoscientific mapping in the Aukam Valley, Namaqua Metamorphic Complex, Southwestern Namibia

Ewereth MUVANGUA[1]*, GEOLOGICAL SURVEY OF NAMIBIA (emuvangua@gmail.com)
Jason Indongo[2], Geological Survey of Namibia
Claudia Mutongolume[3], Geological Survey of Namibia
Paul Macey[4], Council for Geoscience/University of Cape Town

Abstract

The Geological Survey of Namibia has embarked on a joint geological mapping programme with the Council for Geoscience of South Africa in the Namaqua Metamorphic Complex in southern Namibia, which commenced in 2013. The study of the 1: 50 000 scale geological mapping provides new aspects of the regional tectonostratigraphy of the various domains. The Paleoproterozoic Sperrgebiet Domain (~2.02 Ga) and Richtersveld Magmatic Arc (~1.9 Ga) and high grade ~1.3-1.1 Ga Mesoproterozoic rocks of the Kakamas and Aus Domains forms the Namaqua Metamorphic Complex in southern Namibia . The Aukam Valley basement rocks occur as an inlier of the Nama Group southeast of the Aus village. The mapping in this area was limited, with large parts shown as “Undifferentiated Namaqua” on the existing 1:250 000 geological survey map. Our mapping reveals the Aukam Valley geology consists of a variety of high-grade gneisses and granites. Cordierite-sillimanite-garnet-K-feldspar metapelite and associated garnet-quartz-feldspar leucosome bodies, that formed during granulite facies anatexis, are intruded by dykes of mafic granulite and voluminous sheets of coarse-grained and augen-textured leucogranite gneiss. The penetrative gneissic Namaqua fabric extends in the WNW direction and dips to the northeast. The metapelites resemble the ~1.22 Ga Garub and the Narries Groups in the Aus and Kakamas Domains, respectively. Similarly, the leucogranite gneisses are comparable with the ~1.2 Ga Aus Gneiss and Ham Suites of the Aus and Kakamas Domains. The high-grade rocks are intruded by late-tectonic ~1.1 Ga porphyritic enderbite and granodiorite of the Komsberg Suite and ~1.0 Ga pegmatites related to the terminal-Namaqua dextral shear event. The new mapping confirms that the Aukam Valley inlier forms part of the Aus-Kakamas granulite mega thrust sheet. The area is of economic significance as it hosts graphite mineralization at the Aukam graphite mine. Through this mapping programme coupled with detailed research, other potential mineral occurrences may be delineated within the Aukam Valley and surroundings.

U–Pb Geochronology of Detrital Zircons from San Carlos Basin, Costa Rica: Evidence of Miocene Volcanism and Implications for the Precambrian and Paleozoic History of the Central American Isthmus

Martin Rojas Barrantes[1]*, Directorate of Geology and Mines, Costa Rica (martinr@minae.go.cr)
Sofia Huapaya-Rodríguez Parra[2], Directorate of Geology and Mines, Costa Rica
Luigi A. Solari[3], UNAM, México
Vladimír Žáček[4], Czech Geological Survey, Czech Republic

Abstract

Central America encloses a variety of geological units whose evolution is related to six major tectonic plates (North American, Caribbean, Cocos, Nazca, South American) and Farallón during the Lower Miocene, as well as continental and oceanic slivers of tectonostratigraphic blocks (Maya, Chortís, Chorotega, and Chocó), and a possible series of other hidden terranes. The Maya and Chortís blocks are the continental crust, meanwhile, the Chorotega and Chocó blocks are composed of piles of accreted/collided oceanic crust sequences. Southern Central America is characterized by the absence of pre-Mesozoic rocks, in contrast, the northern region of Central America contains a variety of Precambrian/Paleozoic, Triassic metamorphic, and igneous rocks with a wide age range. The San Carlos Basin (SCB) is an extensional back-arc basin located in northwestern Costa Rica and southern Nicaragua (10°22′–11°08′) within the Central American back-arc region, a convergent margin of the Cocos oceanic plate beneath the Caribbean continental plate. The basement of the basin is composed of Middle Jurassic to Upper Cretaceous rocks, mainly mafic and ultramafic rocks and pelagic radiolarites. Likewise, it comprises Paleogene and Neogene volcano-sedimentary rocks. The objective and method were to sample clastic sediments (sandstones) in outcrops and borehole cuttings from the Middle Miocene to Pliocene age sedimentation of the SCB to date detrital zircons through U-Pb/LA-ICPMS standard analysis, in search for information about the geological and tectonic history of this area of southern Central America. The 206Pb/238U ages were considered for dates <1000 Ma, whereas 207Pb/206Pb ages were preferred above such a limit. The majority of the analyzed zircons in all the samples seem mainly to be dominantly of igneous origin, while some crystals may be related to metamorphism. The results show that there is a wide distribution of ages and generations of zircons in the SCB. Twelve per cent of the dated zircon grains are recycled from Paleozoic and Proterozoic sources, whereas 88% of the zircon grains are from the Cenozoic and Mesozoic arc magmatism and volcanism. The most frequent population is Cenozoic (79%), followed by Mesozoic (9%), Proterozoic (8%) and Paleozoic (4%). The Miocene population (66%) was constrained to a maximum depositional age of 6.9 ± 0.2 Ma of late Miocene-Pliocene basin sedimentation. According to the chondrite-normalized REE patterns and U/Yb–Y geochemistry the large majority of the analyzed zircons (96%) have a continental origin, while 6% of the Miocene population shows an oceanic origin probably associated with a MORB-type source arc volcanism. The Cenozoic and Mesozoic detrital zircon ages show the development and evolution

of the southern Central America volcanic arc, while the Proterozoic and Paleozoic detrital zircon ages indicate a possible connection with northern Central America or southern Mexico, or a possible Gondwanic or Laurentian origin. However, it could also indicate the presence of hidden continental crust fragments underneath southern Central America. These ancient detrital zircons ages constitute a new contribution to revealing the evolution of these continental complexes and provide a paradigm for future studies about the geologic and geotectonic evolution of the Central America isthmus.

Abstract

This report systematically sorts out the Meso-Neoproterozoic stratigraphic problems on the Stratigraphic Chart of China (2014), based on the achievements of relevant experts and the author's team in stratigraphic chronology in the past 10 years, and combining with the spatio-temporal development and correlation relationship of geological events, focuses on studying the definition of the bottom boundary of the Mesoproterozoic and the Mesoproterozoic Undefined System, the stratigraphic relationship in the Meso-Neoproterozoic transition period, and the division of the lower boundary of the Cryogenian, as well as the time age of the Ediacaran Luoquan glaciation. On this basis, a subdivision and correlation frame work of the Meso-Neoproterozoic strata of China, were presented and the similarities and differences among the North China, Yangtze, and Tarim Block are further discussed. The researches indicate that it is more reasonable to set 1800 Ma as the lower boundary of the Mesoproterozoic than 1600 Ma; Although the Mesoproterozoic Undefined System is developed in both the northern and southern margins of North China and South China Block, the Shennongjia Group in the northern margin of the Yangtze Block is favorable than others and as a result, suggests it as the temporary stratotype of the Undefined System in China and emphatically research on it; The proto-Qingbaikou System in Jiao-Liao-Xu-huai-Ji-Yu of North China Block, is probably older than 1000 Ma, i.e., parts of it belonging to the Mesoproterozoic; We proposal that the proto-Nanhuan System corresponds to the international Cryogenian (720~635 Ma); The Qingbaikou System is bounded by a tectonic plane

of 820 Ma, with the lower part is named as the Lower Series of the Qingbaikou System (1000~820 Ma), and the upper part is named as the Upper Series the Qingbaikou System (820~720 Ma), and the decision on whether to divide into two systems will be made when there are more evidences in the future; The Luoquan Formation and coeval strata in the southern margin of North China Block probably belong to the upper Sinian. Our researches provide data, evidence and the reference subdivision, to revise and improve for "the Meso-Neoproterozoic" division and correlation in the Stratigraphic Chart of China.

It is co-funded by the National Key Research and Development Program (No. 2022YFF0800302, 2016YFC0601001), the National Natural Science Foundation of China (No. 42072135), the project of China Geological Survey (No. DD20221649) and the International Innovation Resources Cooperation Project of the Beijing Science and Technology Commission (No Z201100008320007).

Meso-Neoproterozoic Simlipal Complex, Eastern India; an impact induced basin, post amalgamation of Singhbhum Craton and North Singhbhum Mobile Belt.

Jayaprakash Mohakul[1]*, Geological Survey of India (jayaprakash.mohakul@gsi.gov.in)
Maya Tripathi[2], Geological Survey of India
Itishree Chinara[3], Geological Survey of India

Abstract

The Simlipal Complex is located at the north eastern periphery of Singhbhum Craton, close to its interface with the Palaeo-Mesoproterozoic North Singhbhum Mobile Belt (NSMB). It is an ovoid basin consisting of three distinct horizons of inward dipping sandstone alternating with mafic volcanic, while the centre is occupied by the differentiated Amjori sill with dunite member at the base, which grades through peridotite, picrite, gabbro, diorite to dolerite at the top (Iyengar & Banerjee, 1964; Iyengar et al., 1981). The present study primarily focuses on the basement cover relationship of the lower most sandstone unit with that of the cratonic mass as well as NSMB, constrain its age based on available data of basement rocks and propose a theory of basin formation due to meteorite impact based on new evidences from the Bhuasuni Felsic Complex at the northern periphery of Simlipal Complex.

The north eastern part of Simlipal Complex is fringed by metamorphosed pelitic and psammopelitic assemblages of NSMB while in the rest of the part it clearly overlies the cratonic mass represented largely by Singhbhum Granite Complex, Mayurbhanj Granite and Gabbro. The basal sandstone layer occurs as a near continuous ring with strata consistently showing moderate dips towards the centre except at the north eastern part where dips are rather shallow. Near horizontal attitude of beds at this part has resulted in several outliers of sandstone clearly overlying the foliated grey phyllite of NSMB which gives a deceptive appearance of bifurcation of lower sandstone. Inclusion of this grey phyllite as a part of Simlipal Complex by many of the early workers is untenable as there is a clear angular unconformity between them. Sandstone is typically fine- to medium-grained, having herringbone stratification, tidal bundles, soft sediment deformation structures along with ubiquitous trough cross-stratification. Petrographic study suggests these sandstones as quartz arenites and reveals their high textural and mineralogical maturity. The Bhuasuni Felsic Complex occurs as a near circular body northeast of the Similipal Complex and west of the southern extension of Singhbhum Shear Zone across which the lithopackage of NSMB are thrusted upon the cratonic mass to the west. Recent work by authors clearly establishes it to be alkali feldspar granite, largely granophyric in nature, showing both plutonic and volcanic variants. Presence of deformational imprints of NSMB indicates it to be synkinematically emplaced during accretion of NSMB with Singhbhum Craton and can be correlated with the Arkasani granophyres. Planar deformation fabric (PDF) in quartz and suspected diapletic glass recorded in the aphanitic variant of Bhuasuni Felsic Complex suggests

that the Simlipal basin could have originated due to meteorite impact.

STRATIGRAPHIC REVISION OF AN EOCENE-MIOCENE CARBONATE-EVAPORITE SUCCESSION IN UAE-OMAN GUIDED BY SENTINEL-2 MULTISPECTRAL DATA ANALYSIS

Abdel-Rahman FOWLER[1]*, UAE University (afowler@uaeu.ac.ae)
Karim Abdelmalik[2], Ain Shams University, Egypt

Abdelaziz Al Azzani[4], UAE University, U.A.E.
Mahmoud Abu Saima[5], UAE University, U.A.E.

Abstract

The carbonate-evaporite sequence exposed at Jabal Hafit, south of Al-Ain, Abu Dhabi Emirate, is the most complete Eocene to Miocene succession in the UAE. Stratigraphic subdivision of this ~ 1200 m thick sequence began in the late 1970's as part of hydrocarbon exploration activities in the region. The currently accepted stratigraphic scheme for the Jabal Hafit sequence dates from 1984 and includes (from oldest to youngest) the Lower Eocene Rus Formation (nodular wackestone, marl, coralgal and gastropodal grainstones, foraminiferal stylonodular packstones, and dolomite), Middle to Upper Eocene Dammam Formation (brown marls, massive Nummulitic limestones, and brown coarse-grained calcarenites), the Oligocene Asmari Formation (green marls, Nummulitic wackestone-packstone and coralline reefal boundstone), and the Miocene Lower Fars Formation (gypsiferous mudstones and gypsite). Division of the formations into members has been suggested based mainly on mapping in the northern (UAE) part of Jabal Hafit. Mapping of the extent of the formations and members, and recognition of facies variations within each unit, in the southern (Omani) parts of Jabal Hafit, have been hampered by the mountainous terrain of Jabal Hafit, poor accessibility, international border restrictions and poor discrimination of the mainly carbonate rocks on unprocessed satellite images. In this work, remote sensing techniques, including Principal Component Analysis, improved by Decorrelation Stretching, have been applied to Sentinel-2 data for the Jabal Hafit area in UAE and Oman. The results provide excellent discrimination of the formations and members of the Hafit sequence, including the first mapping of the members of the Rus Formation that mainly occupy the crest of Jabal Hafit.

Are Ordovician ferruginous ooids and microbialites indicators of cool-water realms and upwelling-active zones?

Xiaocong LUAN[1]*, Nanjing institute of Geology and Palaeontology, CAS (xcluan@nigpas.ac.cn)
Jisuo JIN[2], Western University

Renbin ZHAN[4], Nanjing institute of Geology and Palaeontology, CAS

Abstract

The Phanerozoic Ooidal Ironstone (POI) is an important ore and usually considered as the result of warm climate, but POI in Ordovician, as one of the richest periods, mostly develops with cool-water faunas and sediments. It is also suggested by the distribution of most Ordovician POI in high-latitude Gondwana area. This study examines the Middle–Late Ordovician POI in South China, a unique warm-water anomaly, and coeval ferruginous deposits (iron ooidal limestone and ferruginous microbialites). These ferruginous deposits can be divided into ferruginous ooids (Types A and B) in warm-waters carbonate and microbialites (Types C and D) in cool-water sediments, controlled by depositional differentiation. Their similar structures and δ56Fe values suggest a shared iron source and formation pathway, in relation to dominant cool-water ramp with active upwelling background. This hypothesis is attested by the integrated summary of global distribution of Ordovician ferruginous deposits, revealing a consistent association with cool-water realms and upwelling-active zone. Along with global cooling, the unique ocean–land configurations contributed to the formation of Ordovician POI and other ferruginous deposits. The Darriwilian peak in POI abundance corresponds not only to intensified upwelling but also to the emergence of ice sheets, indicating the potential link between glaciation and the ocean-atmosphere circulations.

Abstract

Following the successful conclusion of the Southern Namibia Mapping Program (SNMP), a 10-year joint venture between the Council for Geoscience (CGS) and the Geological Survey of Namibia, we have embarked on an in-depth exploration of the Paleoproterozoic Richtersveld Subprovince/Magmatic Arc (RMA). The RMA, part of the Namaqua Metamorphic Province, spans southern Namibia and adjacent NW South Africa, and has been the subject of extensive study aiming to unravel its complex evolutionary history. Integrating recent findings with previous work from this study, has led to a comprehensive model for the evolution of the RMA, shedding light on its tectonic and magmatic processes.

The RMA was variably affected by the ~1 Ga Namaqua orogeny. In the west, low-grade metamorphic rocks (Vioolsdrif Domain) record a limited Namaqua imprint whereas in the east, the equivalent rocks were converted to amphibolite-facies gneisses (Pella Domain). Tectonic slivers of RMA rocks are also found in an imbricate thrust zone that forms the base of the over-riding Namaqua age Kakamas Domain further east.

The volcanic and equivalent plutonic rocks (Orange River Group (ORG) and Vioolsdrif Suite respectively) of the RMA form a coeval calc-alkaline magma series with characteristic island-arc geochemical signatures. The entire magmatic history took place between 1910 and 1865 Ma, contrary to the much longer timespans previously suggested.

Recent geological mapping, U-Pb LA-ICPMS zircon geochronology, and Sm-Nd isotopic studies conducted during the SNMP reveal older crustal "rafts" hosted within the RMA. These include inherited zircons in RMA plutonic rocks (~1.9 Ga Vioolsdrif Suite) and detrital zircons in coeval

RMA meta-sedimentary rocks (Orange River Group), indicating ages ranging from Neoarchaean to Paleoproterozoic (~3.3 to 2.0 Ga). Nd isotopic data further supports the presence of older crust within the source region of RMA magmas.

The SNMP has identified the ~2.02 Ga inheritance and detrital zircon peak in the RMA rocks as sourced from the Wasserkuppe Suite of the Sperrgebiet Domain, a pre-existing arc domain cannibalised by the RMA. Moreover, two older crustal rafts have been discovered, the Bankwasser Migmatite (~2.9 – 2.5 Ga detrital ages) and an even older Archaean crustal inclusion, the Blue Mountain Group (3.3 -2.7 Ga) on the NW margin of the RMA, providing further evidence of ancient crustal components within the RMA. U-Pb analyses of detrital zircons obtained from the nearby Neoproterozoic low-grade diamictite (Halifax Formation) of the Gariep Supergroup yield a broad range of ages from 3.3 to 1.0 Ga, with the older detritus affirming the presence of ancient crust in the vicinity, thereby underscoring the heterogeneous nature of the RMA.

These findings emphasize the importance of continued mapping and geochronology in resolving the complexities of geological terrains. The integrated approach employed in this study provides crucial insights into the evolution of the RMA and broader geological processes in the region, contributing to our understanding of crustal evolution and tectonic dynamics in Paleoproterozoic settings.

Abstract

To the east of the Ecuadorian Andes, the Cordillera Real represents a core of sedimentary and metamorphosed igneous rocks, which traditionally has been studied in terms of lithotectonic terranes: Guamote, Alao, Loja, Salado, Zamora. Previous research considered the Salado Terrane as a marginal basin of the Jurassic to Cretaceous age, which developed on the edge of the South American craton and within which the Upano, Cuyuja, Cerro Hermoso, and Azafrán units were deposited. Along the Cuyuja to Baeza route, the Cuyuja Unit extensively outcrops in the Yaguana Ravine (UTM: 833320E, 9954106N). The Cuyuja Unit unconformably overlies the Upano Unit. At the base of the Cuyuja Unit, meta-conglomerates are observed, matrix-supported, silicified, with sub-rounded quartz granules and clasts, intercalated with quartz ± graphite ± muscovite schists and black phyllites. The top of the Cuyuja Unit is dominated by phyllites, shales, graphite ± sericite schists, and meta-sediments. The meta-sediment levels consist of intercalations between metapsamites and metapelites where remnants of tidal structures are observed: wavy lamination, flaser bedding, and bidirectional ripples. The provenance and tectonic environment of the Cuyuja Unit in the Yaguana Ravine were evaluated through whole-rock geochemistry. The Cuyuja Unit exhibits SiO2 and Al2O3 contents comparable to the average composition of the upper continental crust (UCC). These rocks are strongly depleted in CaO and MgO and enriched in K2O, Ba, and Rb relative to UCC, reflecting the addition of K during diagenesis. Zr, Ti, and Ni ratios suggest that the Cuyuja Unit originated from a sedimentary protolith. The REE patterns normalized to PAAS are nearly flat, with a slight depletion of LREE relative to HREE and null or weakly positive Eu anomalies. Their REE patterns normalized to chondrites are parallel to sub-parallel, enriched with LREE, and show distinct negative Eu anomalies and weakly fractionated HREE segments. Overall, they are geochemically mature and have undergone sedimentary recycling. The La, Th, and Hf ratios indicate an increase in an ancient sedimentary component, probably from a cratonic source, deposited on a passive margin. U-Pb ages in detrital zircons results show the dominant influence of cratonic sources east of the basin, yielding prevailing age groups of 1550–1300 Ma (Rodonian-San Ignacio) and 1300–900 Ma (Sunsás) from the westernmost cratonic provinces. Secondary cratonic sources (~25%) include older eastern provinces such as Rio Negro-Juruena (1800–1550 Ma) and Ventuari-Tapajós (2150–1800 Ma). Minor Neoproterozoic-early Paleozoic populations suggest limited input from the Andean metasedimentary basement (200 –150 Ma).

When and how did the Sturtian glaciation begin? insights from the Shennongjia area, northern Yangtze Craton

Yuchong Wang[1]*, Institute of Geology, Chinese Academy of Geological Sciences (yuchongwang@Foxmail.com)
Hongwei KUANG[2], Institute of Geology, Chinese Academy of Geological Sciences
Yongqing LIU[3], Institute of Geology, Chinese Academy of Geological Sciences

Kening QI[7], Institute of Geology, Chinese Academy of Geological Sciences

Abstract

The two low-latitude glaciations, commonly referred to as the "snowball Earth", occurred during the Cryogenian, were periods of unprecedented frigidity in Earth's history that exerted a profound influence on the evolution of life and global environments. Supported by the National Key Research and Development Program of China (No. 2022YFF0800302 and No. 2016YFC0601001), this study analyses the sedimentary evolution of the northern Yangtze Craton from the late Tonian to the Early Cryogenian based on the continuous sedimentary record of the Shennongjia region in the northern Yangtze Craton, and explores the onset of the Sturtian snowball Earth. Initial deposition in the northern Yangtze Craton began around 767.3 ± 6.1 Ma and the sedimentary environment was dominated by terrestrial fluvial action with a provenance from the continental magmatic arc on the South Qinling Belt. Around 753.8 ± 2.9 Ma, a sedimentary translation from the fluvial-dominated terrestrial system to the transgressive tidal-influenced marine system, which coeval with the peak rifting related to the supercontinent Rodinia breakup. Approximately 722.5 ± 2.1 Ma, the northern Yangtze Craton experienced a period of intense chemical weathering and enhanced water cycle, followed by the distal glaciomarine ice-rafted deposits and then proximal glaciomarine subaqueous debris flows. The sedimentary sequences, isotopic ages, and geochemical data analyzed in this study suggest that the initiation of the Sturtian glaciation in the Shennongjia area of the northern Yangtze Craton occurred after 723 Ma, which aligns with the timing of the onset of glaciation in the Laurentian Craton. Furthermore, these results provide new insights and basic data for understanding the onset of the snowball Earth, thereby supporting the continental weathering hypothesis of the supercontinent Rodinia as a trigger for the Sturtian glaciation.

Factors affecting sequence structure and sequence-stratigraphic dynamics

Haoyuan LV[1]*, College of Energy Resources, Chengdu University of Technology
(lvhy97@qq.com)
Guoqiang XU[2], College of Energy Resources, Chengdu University of Technology

Abstract

The stratigraphic structure pattern and phase distribution in the third-order sequence are mainly controlled by three factors: periodic sea level change, tectonic uplift and decline, and sediment supply rate. Among them, periodic sea level change is the basic driving force of sequence structure change. Tectonic processes and sediment supply in different periods in different regions can affect the change of relative sea level or base level, which is the external driving force of stratigraphic structure change. Sequence-stratigraphic dynamics mainly investigate how the above three factors collectively drive variations in the sequence-stratigraphic architecture. The influence of three factors on the sequence structure can be summarized into the following three patterns: (1) When the basement subsidence and sediment supply rate are normal, a base-level cycle corresponds to four genetic stratigraphic units: transgression unit, highstand normal regression unit, forced regression unit and lowstand normal regression unit; (2) When the subsidence rate of the basin is high or the sediment supply rate is low, the scale of transgression unit will increase, the scale of forced regression unit will decrease, and the types of genetic unit in a single sequence will decrease. On the contrary, when the rate of tectonic uplift is high, the scale of regression unit will increase, and the transgression unit will decrease; (3) When the subsidence rate is particularly high and the sediment rate is normal, the relative sea level change of the third-order cycle shows a rapid rise, and the strata are all the genetic units of transgression, and the third-order sequence cannot be identified by the transgressive and regressive cycle. When the rate of tectonic uplift is particularly high, the strata all converted to forced regression units.

Provenance of Late Precambrian quartzite- schist sequences of the western Central Asian Orogenic Belt

Nadezhda KANYGINA[1]*, Geological Institute, Russian Academy of Sciences, Moscow, Russia (kanygina.nadia@gmail.com)
Andrey Tretyakov[2], Geological Institute, Russian Academy of Sciences, Moscow, Russia
Kirill Degtyarev[3], Geological Institute, Russian Academy of Sciences, Moscow, Russia
Anfisa Skoblenko[4], Geological Institute, Russian Academy of Sciences, Moscow, Russia

Abstract

The Central Asian Orogenic Belt (CAOB) is the largest accretionary orogen in the world formed during evolution of the Paleo-Asian Ocean through the accretion and collision processes of the late Precambrian to early Mesozoic age. The terranes with Precambrian continental crust play a significant role in the structure of the western segment of the CAOB. Meso- and Neoproterozoic igneous and metamorphic formations mostly comprise the Precambrian terranes in this part of the belt, whereas Early Precambrian complexes are extremely limited (Degtyarev et al., 2017).

Another characteristic feature of the Precambrian terranes is the presence of late Precambrian sedimentary and metasedimentary formations, which mostly include metaterrigenous schist, quartzite schist and quartzite. Their widest distribution is known from the Northern Kazakhstan (Kokchetav, Ishkeolmes, Erementau–Niyaz), Aktau–Yili (Aktau–Mointy, Junggar Alataw, Yili block), Chu–Kendyktas, Issyk–Kul and Chinese Central Tian Shan terranes (Degtyarev et al., 2017).

The accumulation of these units began approximately at ca. 1.1 Ga, and their sources were Mesoproterozoic, Paleoproterozoic and Neoarchean complexes (Kanygina et al., 2021). When comparing detrital zircon ages from the quartzite–schist sequences of the Aktau–Mointy, Junggar Alataw, Northern Kazakhstan and Issyk–Kul terranes, similarities in age distributions are observed. However, the Aktau–Mointy and Junggar Alataw terranes sequences are characterized by a significant predominance of early Mesoproterozoic–Paleoproterozoic (1400–1800 Ma) detrital zircon ages, while the Northern Kazakhstan and Issyk–Kul terranes exhibit the predominance of Mesoproterozoic (1200–1500 Ma) detrital zircon ages.

Quartzite-schist and quartzite-schist-carbonate sequence with similar structures and ages are developed within the Yili block and Chinese Central Tien Shan in the west CAOB. Detrital zircons here have similar age distributions and εHf(t) values. The accumulation of strata of these terranes began at ca. 1000 Ma, and the main sources were Mesoproterozoic, Paleoproterozoic and Neoarchean complexes. Quartzite- schist sequences are also developed in the structure of the Chu-Kendyktas terrane but their accumulation began around 1700 Ma and Paleoproterozoic and Neoarchean complexes prevailed in the provenance (Kanygina et al., 2021). The Early Neoproterozoic sedimentary strata of the northern part of the Tarim Craton also lacking detrital zircons aged 1200 - 1700 Ma.

The structural features of the stratigraphy and sedimentation environments and the age range and nature of the quartzite–schist sequence provenance areas of the Late Mesoproterozoic to Early

Neoproterozoic indicate the proximity of the Aktau–Yili, Chinese Central Tian Shan, Kokchetav, Ishkeolmes, Erementau–Niyaz and Issyk–Kul terranes that likely formed a single continental block during that period, while they show significant differences with the Late Precambrian formations of the Chu-Kendyktas terrane and Tarim Craton (Kanygina et al., 2021).

This study was financially supported by the Russian Science Foundation (Grant No. 22-77-00082) and was conducted following the plans of the scientific research of the Geological Institute of RAS.

Vanadium isotope reveals the interval of marine oxygenation during early Cambrian, South China

Hao RAN[1]*, Development Research Center, China Geological Survey (ranhao@mail.cgs.gov.cn)
Zhixun LIU[2], Development Research Center, China Geological Survey
Tao ZHANG[3], Development Research Center, China Geological Survey

Abstract

The early Cambrian is a key period to understand the co-evolution of the paleo-marine environment and biotic events. However, the process of marine oxygenation in the early Cambrian is still hotly debated. Vanadium isotope system in fine siliclastic sediments is widely used to investigate rapid marine redox fluctuations . In this study, we analyze V isotope composition (δ51V) of Liuchapo and Niutitang Formations deposited in the early Cambrian, from the Yangtze Block, western Hunan, South China. The isotope values (δ51Vauth) of authigenic V (from -0.72‰ to -0.38‰) from the upper Liuchapo and lower Niutitang Fromations indicate the anoxic depositional environment. The values of δ51Vauth (from -0.31‰ to -0.14‰) from the middle Niutitang Formation indicate the euxinic environment (presence of H2S). However, the low value of δ51Vauth (-0.66‰) from upper Niutitang Formation indicates that the depositional environment changes back to anoxic environment. It records the occurrence of euxinic environment of slope during the stage 3 of the early Cambrian. The low values of open-ocean seawater δ51V (δ51Vosw) (from -0.71‰ to -0.54‰) from middle Niutitang Formation are significantly lower than the modern δ51Vosw value (+0.20‰ ± 0.15‰). It suggests that the local redox environment is consistently oxygen-depleted during the deposition of Liuchapo and Niutitang Formations in South China. As one of the most pioneer representative area for biodiversification in early Cambrian, the presence of free oxygen in South China seems relatively restricted and the secular oxygenation process is not successive during early Cambrian, which is inconsistent from previous Mo and V isotopes studies.

40Ar/39Ar ages from rocks of the southern part of the Mozambique Belt

Umberto Giuseppe Cordani[1], University of São Paulo
Fátima Roberto Chaúque Nampete[2]*, National Institute of Mines (fchauque27@gmail.com)
Maria Helena Bezara Maia De Hollanda[3], University of São Paulo
Caetano Juliani[4], University of São Paulo

Abstract

Thirteen 40Ar/39Ar age determinations were made on ten rocks of central-western Mozambique, at the southernmost part of the Mozambique Belt. The study area includes the eastern tectonic contact of the Zimbabwe Craton with two nappes of Pan-African age, formed when the Kalahari and Antarctica continental blocks collided at about 520-500 Ma, during the Kuunga Orogeny. Peak metamorphism in that region is set at about 500 Ma by zircon overgrowth in granitoid rocks. The measurements included two biotites and one amphibole taken from two granitoid rocks of the northern Mungari Nappe, three biotites and two amphiboles taken from four medium-grade rocks near Chimoio at the southern part of the Chimoio-Macossa Nappe, as well as a biotite and a muscovite from a quartzite of the Gairezi Formation, located near the contact with the Zimbabwe Craton. With one exception, a biotite with 488 Ma of an orthogneiss near the town of Sussundenga, these 40Ar/39Ar ages were enclosed within the 455-475 Ma time interval, dating the regional cooling age related to the 300oC isotherm. However, a much younger cooling age was registered for biotites taken from three high-grade paragneisses with garnet, cordierite and sillimanite, located near Macossa. These Pan-African rocks presented detrital zircons with maximum ages close to 700 Ma. Their 40Ar/39Ar ages, as young as 400 Ma (lower Devonian), may indicate a thicker crust in the eastern part of the Chimoio-Macossa Nappe, where the material was subjected to high-pressure metamorphism and brought to the surface after a long lasted exhumation.

Tectonics and Geodynamics of Antarctica

German LEICHENKOV[1]*, Institute for Geology and Mineral Resources of the World Ocean (german_l@mail.ru)
Garrik E Grikurov[2], Retired

Abstract

Antarctic region extends from 60S to the South Pole and includes the Antarctic continent surrounded by the southern parts of Atlantic, Indian and Pacific Oceans. The continent is almost completely (over 14 million sq.km, by 99%) covered by ice with an average thickness of 1.9 km. Since the outbreak of scientific exploration of the continent, its tectonic interpretations have advanced from the earliest simplistic sketches to modern geodynamic models, which, however, still remain largely speculative due to shortage of direct geological evidence. Views developed prior to the 2007-2009 International Polar Year were synthesized in the first edition of the International Commission for Geological Map of The World (CGMW) 1:10,000,000 Tectonic Map of the Antarctic published in 2012. Subsequent accumulation of data required updating of this map and preparation of the second upgraded edition, which was published in 2023. The new map gives realistic presentation of actually mapped tectonic units against their inferred subglacial extrapolations; provides an advanced characterization of the East Antarctic crystalline basement complexes by showing the ages of protolith emplacement and subsequent reworking events; visualizes the polyphase magmatic arc history of the onshore part of the present-day Pacific margin; offers a more accurate structural image of Antarctica's continental margin, including the position of marginal rifts, the location of the continent-to-ocean boundary and the distribution of sediment thickness; displays the refined ages of oceanic crust based on revised identification of magnetic anomalies. Archean complexes are grouped in the legend in a separate block designating the continental protocrust that lacks clear plate tectonics markers. Protocrustal inheritance is found in many Proterozoic rocks previously viewed as the juvenile additions. With rare exceptions, most orogenic complexes reveal crustal residence considerably pre-dating the age of final stabilizing event. The Pacific margin of Antarctica represents the amalgamation of proximal para-autochthonous fragments of diachronous magmatic arcs that experienced transpressional displacements relative to the in situ Gondwana crust and were partly rimmed by the allochthonous accretionary wedges. A large part of Antarctic landmass and its sub-bottom margin is occupied by sedimentary basins formed on rifted (stretched and thinned) continental crust in the course of Gondwana breakup and opening of the Southern Ocean. The continental margin comprises magma-rich and magma-poor segments. Extreme crustal stretching of magma-poor margins is documented within the zones of dramatic seaward necking of continental crust and its substitution by the serpentinized and exhumed continental mantle material. Disengagement of the Antarctic continental fragment from Gondwana began in Middle Jurassic time in the Atlantic sector of the present-day Southern Ocean. It progressed with seafloor spreading in a clock-wise direction, until completed in the Cenozoic by separation of landmasses in the Indian and Pacific sectors.

Generalized view of Antarctic tectonic structures, including their inferred distribution under ice, is provided in a smaller-scale inset. It also shows the rates of sea-floor spreading and areas with thickened oceanic crust. The map is accompanied by extended Explanatory Notes booklet with illustrations and references. The Map and Explanatory Notes can be found at https://ccgm.org/en/catalogue/.

Discovering Remnants of the Earliest Continents: 3.4 Ga Basement in the South West Terrane of the Yilgarn Craton and Implications for Archean Geodynamics

Catherine GILL[1]*, University of Western Australia (cat.gill@research.uwa.edu.au)
Nico Thébaud[2], University of Western Australia
Naomi Tucker[3], University of Western Australia
Tony Kemp[4], University of Western Australia
Raphael Quentin de Gromard[5], Geological Survey of Western Australia
Tim Ivanic[6], Geological Survey of Western Australia

Abstract

Our geochronological study documents previously unrecognised 3.4 Ga migmatitic gneisses forming the basement of 3.3 – 3.2 Ga supracrustal successions in the South West Terrane of the Archean Yilgarn Craton in Western Australia. Our results do not match any other magmatic or gneissic units within the Yilgarn craton, returning older ages than adjacent terranes to the east but generally younger ages than the Narryer Terrane in the north. Combined with detrital spectra in derived from quartzites belonging to the overlying greenstone sequence, our data suggests that the South West Terrane did not share the same history with the rest of the Yilgarn and may be an exotic component appended to the craton later in its evolution.

This study builds off recent work by the Geological Survey of Western Australia, who have rearranged the boundary between the South West and Youanmi Terranes (Quentin de Gromard et al., 2021) of the Yilgarn Craton which were initially outlined in Cassidy et al., (2006). The terrane boundary now aligns with a highly deformed and metamorphosed belt known as the Corrigin Tectonic Zone. In the context of Cassidy et al., (2006), terranes are defined as fault-bounded bodies of rock, characterized by a geologic history different from that of contiguous terranes. Meaning that the boundaries between the terranes must be tectonically significant, preserving evidence relating to early-earth continent assembly. Accordingly, the recent changes and data presented in this study suggest that the Corrigin Tectonic Zone could represent a suture zone of two unrelated crustal blocks or Terranes. This preliminary conclusion provides an opportunity to discuss early earth continental assembly with specific reference to the Yilgarn Craton.

Picture Perfect Photogrammetry: mapping the remnants of long-gone glaciers in northern Namibia in unprecedented resolution

Ricarda WOHLSCHLÄGL[1]*, University of Vienna (ricarda.wohlschlaegl@univie.ac.at)
Christoph KETTLER[2], Geosphere Austria

Daniel LE HERON[4], University of Vienna
Andreas NDUUTEPO[5], Geological Survey of Namibia

Abstract

Extensive research is continuously improving our picture of the penultimate and most widespread icehouse interval of the Phanerozoic – the Late Paleozoic Ice Age (LPIA). As a result, the blank spots on reconstructed paleo-maps are gradually filling in, but entire regions of the former supercontinent Gondwana have still been neglected. Today's northern Namibia is one of them.

The glacial features of the LPIA in northern Namibia have been disproportionately understudied compared to the southern part of the country.

The initial insights gained from mid-20th century expeditions (e.g. Martin & Schalk, 1959) form the basis for the long-overdue reinvigoration of research in this remote region (e.g. Fedorchuk et al., 2023) – but this time equipped with the rapid technological progress of the 21st century.

Utilizing advanced techniques of aerial and close-range photogrammetry, we have conducted a thorough mapping of former glacier beds at an unprecedented resolution. Quantitative analyses of macroscale ice flow features, including over 16,000 measurements of striae and crescentic markings, allow us to determine the directions of ice flow with great precision and to correlate the results with the suggested local flow directions of a large-scale paleo-fjord network (Dietrich et al., 2021). This approach enables previous issues of conflict in the literature, specifically confusion over ice-flow directions, to be resolved. In turn, it has major implications for accurate paleo-glacial reconstructions.

By examining specific regions of potential subglacial bedrock failure using high-resolution outcrop photos and detailed 3D models, we have investigated the impact of meltwater and overlying ice masses on erosional features like crescentic markings and joint-bounded scars. Our discoveries raise significant questions regarding the conditions beneath the glacier, including the different glaciation phases evident in the exposed bedrock, subglacial bedrock failure, and the extent and influence of meltwater activity.

In summary, deploying a photogrammetric approach to the former glaciated landscapes of Namibia greatly improves our understanding of the behavior of LPIA ice masses on Gondwana.

Modern ocean island basalt–like 182W signature in Paleoarchean mafic rocks: A negative μ182W endmember in the lower mantle

Qing-Feng MEI[1]*, Institute of Geology and Geophysics, Chinese Academy of Sciences (meiqingfeng@mail.iggcas.ac.cn)
Jin-Hui YANG[2], Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

Komatiites and picrites generated by high degrees of mantle partial melting serve as potential probes of Earth's deep mantle. Tungsten (W) isotopes in these rocks offer a rare chance to better understand early differentiation, late accretion, core-mantle interaction, and subsequent evolution of Earth's mantle. We present new W isotope data for Archean komatiites and basalts from the Barberton (South Africa) and Suomussalmi (Finland) Greenstone Belts and Permian picrites from the Emeishan large igneous province (China). The Paleoarchean samples from the Barberton Greenstone Belt have modern ocean island basalt (OIB)–like μ182W values ranging from –20.4 to +5.6, whereas the Mesoarchean komatiites from the Suomussalmi Greenstone Belt show μ182W values of –2.2 to +11.3. The Permian Emeishan picrites give μ182W values of –7.1 to +3.1. Notably, our Paleoarchean Kromberg sample has a μ182W value of –19.1 ± 4.3 (2SE), identical to the most negative μ182W value observed in modern OIBs (–22.7 ± 3.3, 2SE). The negative μ182W values of Paleoarchean samples in the Barberton Greenstone Belt and modern OIBs likely result from either early differentiation or core-mantle interaction and indicate the long-term preservation of a negative μ182W endmember in the Earth's lower mantle. Moreover, Phanerozoic plume-derived rocks (e.g., Emeis- han picrites in this study) indicate that recycling of crustal materials and mantle mixing would have partially homogenized W isotopes in the lower mantle since the onset of plate tectonics on Earth.

Sequence biostratigraphy of early Paleogene lignite-shale succession of western India: A case study on an integrated approach to Hydrocarbon Exploration

Shalini PARMAR[1]*, Banaras Hindu University (shalinigary02@gmail.com)
Vandana Prasad[2], Birbal Sahni Institute of Palaeosciences

Abstract

Hydrocarbon exploration in a sedimentary basin requires an understanding of the superposition and lateral arrangements of the depositional sequences to delineate the spatial and temporal distribution of coal/lignite beds and potential reservoirs within a stratigraphic window. In a coastal setting, the vertical and lateral deposition of these sequences are controlled by the ratio of the rate at which accommodation space is being created below the depositional base level to the rate at which the space is being filled with sediment supply following the marine transgression and regression. Over the last few decades, sequence stratigraphy has been an efficient tool in discovering the good quality hydrocarbons as it enables to describe, analyse, and categorize the genetically related strata of the depositional sequences. In hydrocarbon exploration, microfossils are another crucial tool since they provide correlation of strata, age determination and paleoenvironmental interpretation of contemporaneously deposited sequences. Although sequence stratigraphy is frequently employed in exploration, very few studies consider microfossils which typically offers more detailed interpretations. With the integration of biostratigraphic data (microfossils) to sequence stratigraphy, the sequence biostratigraphy technique has evolved, allowing the estimation of age of the flooding surfaces as well as depositional cycles based on the distribution of microfossils in the sedimentary succession. The sequence biostratigraphy can offer more precise data for defining the 3rd order sea level fluctuations during the deposition of sedimentary successions.

Palynomorphs (dinoflagellate cysts, foraminifera, nannofossils and, spores and pollen) are among the most important microfossil groups that helps in developing the precise sequence biostratigraphy of sedimentary succession. The organic walled microfossils (dinoflagellate cysts, pollen and spores) with high abundance in the sedimentary deposits of a shallow marine region are useful owing to their microscopic size and resistance to acidic treatments. The study of palynomorphs (palynology) has considerably strengthened the system tracts models by offering more reliable assessments of bounding surfaces and categorization of genetically related strata. Within the depositional sequences, palynomorphs assemblage characterized by fluctuating relative abundance and diversity of marine (dinoflagellate cysts) and terrestrial palynomorphs (spores and pollen) reflect the changes in sea level. An increase in the abundance and diversity of marine palynomorphs represents the maximum flooding surfaces (MFS) during the marine transgression. On the other hand, the richness of terrestrial palynomorphs suggests high sediment supply during the still stand or slowly falling sea level (regression). Other than that, a coastal region associated with paralic mires exhibits distinctive facies in coal and lignite bearing sedimentary sequences following the transgressive-regressive cycles.

With a combined sedimentological and palynological data, shallowing and deepening upward facies have been demarcated precisely by observing the variations in facies pattern and palynomorphs assemblage in early Paleogene lignite-shale succession of the Barmer Basin, Rajasthan, India. Along the western continental margin of India, the succession shows the 2nd and 3rd order sea level changes, with parasequences and hemicycles corresponding to transient marine invasions (higher order) during early Paleogene period. Thus, the sequence biostratigraphy provides a more accurate framework of transgressive-regressive cycles in a basin which is extremely important in hydrocarbon exploration.

Abstract

The Iberian Massif offers the most extensive exposure of Variscan and pre-Variscan rocks across Europe. It has been partitioned into various tectonometamorphic zones, namely the Cantabrian, West-Asturian-Leonese, Galicia-Trás-os-Montes, Central Iberian, Ossa-Morena, and South-Portuguese Zones, arranged from north to south. The Central Iberian Zone (CIZ) is distinguished by the presence of numerous Variscan granitoids that have intruded into autochthonous Neoproterozoic to Paleozoic metasedimentary and igneous rocks. These rocks are part of the continental margin of Gondwana and provide evidence of both the Cadomian orogeny and the Cambrian-Ordovician rifting. Another feature is the unconformity of Lower Ordovician rocks (Armorican Quartzite) over Ediacaran - lower Cambrian rocks (Schist-Greywacke Domain). This study aims to provide a stratigraphic synthesis of this sequence in Portugal, namely in the Ediacaran sequence (Beiras sector) and its correlation with Spanish sequences recently described.
In Portugal the "Schist-Greywacke Domain" sequence has been recently reviewed into Douro Group (Ediacaran to lower Cambrian), and Beiras Supergoup (Ediacaran). The latter is composed of two separate metasedimentary sequences, namely the Fróia and Lousã groups, which are separated by an intra-Cadomian (Alcudian) unconformity. A correlation is made with the Spanish sequences of the lower and upper Alcudian, respectively.
The cartographic and structural evidence of this unconformity is presented and a critical analysis of the lithostratigraphic proposals currently under discussion is made.

Zircon U-Pb-Hf isotopic age of gneissic inlier of Aravalli Fold Belt, Rajasthan, India: evidences of Protracted crustal building events from Archean to Mesoproterozoic.

Krishnapriya BASAK[1]*, Geological Survey of India (kbasak.gsi@gmail.com)
Siladitya Sengupta[2], Geological Survey of India

Abstract

Aravalli Fold Belt (AFB) represents a Proterozoic accretionary fold belt bordering the cratons of Aravalli of north western India. Sarara inlier is one of the few orthogneissic bodies that occur within AFB as basement inlier. The lithological contact between the ASG and gneisses of inlier is highly sheared with the formation of mylonitic foliation, shear bands and stretching lineation in both the rock groups. The field observations suggest that gneisses of inliers and supracrustals of AFB have participated in major deformation events during evolution of the belt.

The geochemistry of the gneisses dominantly corresponds to more evolved, calc-alkaline, crustal melt with volcanic-arc granitic signature.

One of the orthogneisses of Sarara yielded euhedral zircons with homogeneous core and fine concentric zoning at rim. Often the cores are full of inclusions. Th/U ratios of zircons vary between 0.40 and 1.15. Th/U ratio is indistinguishable from zircons of different ages. Interestingly, homogeneous core and rim with concentric zoning yield similar age. Zircons of this Gneiss yield two dominant clusters of age with minor Archaean population. The dominant and concordant age clusters are at 1847.7 Ma and 2550 Ma. Few zircon analyses yield slightly discordant Archaean age of 3100 Ma.

These zircons are characterized by homogeneous Hf isotopic composition having 176Hf/177Hf isotopic ratio of 0.2815-0.2816 with εHf (t) of -2.9 to -8.6. The εHf (t) values of 2550 Ma zircon are dominantly negative and Archaean grains show positive values. The negative and unimodal distribution of εHf (t) values for 2550 Ma, imply involvement of crustal component at source. The Archaean xenocrystic zircons and 1850 Ma zircons have high positive εHf (t) value of + 11.2 implying their derivation from a depleted mantle source.

The 3100-3063Ma xenocrystic zircons indicate crustal growth and cratonization of this part of the Aravalli Craton of India during Archaean. The two dominant populations of zircon age may reflect crystallization of the orthogneiss during 2550 Ma that experienced extensive remelting or modification during later orogenic event at 1850 Ma. The age 3100 Ma is considered to be the oldest magmatic event to form the initial crust followed by 2500 and 1850 Ma events. Another possible interpretation is that orthogneiss is a 1880 Ma igneous rock with inheritance of 2550 Ma and some minor inheritance of ca. 3100 Ma xenocrystic zircons.

Lithostratigraphy, structure and metamorphic evolution of Naga Metamorphics, Nagaland, India

NEIPEKREIZO KESIEZIE[1]*, GEOLOGICAL SURVEY OF INDIA
(neipekreizo.kesiezie@gsi.gov.in)
Dileepkumar Reddy[2], GEOLOGICAL SURVEY OF INDIA
Ranjit Gangadhar Khangar[3], GEOLOGICAL SURVEY OF INDIA

Abstract

The Naga Metamorphic Group in Naga-Arakan Orogeny of North-East India on the Indian plate are parts of the over-riding Burmese tectonic plate with wedge remnants of dismembered Ophiolite units in between. The lithostratigraphy, structural and metamorphic evolution of these rocks are not well established till date. This study intends to solve this conundrum based on field evidences, petrography and geochemistry. The study area exposes serpentinized peridotite, parts of the dismembered Ophiolite units, phyllite, arkosic quartzite and schist intercalations with limestone and marble which are part of the Nimi Formation whereas schists and phyllite intercalations with arenitic quartzites and micaceous quartzite with ptygmatically folded quartz veins belonging to the Saramati Formation.The regional strike of the area is NE-SW. Two phases of deformation are observed with intense first phase deformation evidenced by parallel secondary and primary foliation. Foliation boudins, large scale recumbent folds and other structural evidences defines second deformation event. The younger Nimi Formation is less deformed and metamorphosed than the older Saramati Formation. The quartz piezometric study of these rocks indicates that there is a gradual transition from primary to advanced quartz recrystallization stages, from younger to older units implying gradual increase in temperature. Oldest lithounit in SaramatiFormation have undergone very high temperatures resulting in complete grain size reduction and in the verge of remelting. Schists, phyllites, and slates of Nimi Formation have narrow ranges of major oxide concentrations with SiO2 (49.96-76.33%), TiO2 (0.37-1.54%), Al2O3 (15.96-23%), MgO (0.47-2.59%) and CaO (0.1-5.96%) are considered as high-Al metapelites. Meta arenites comprises quartzites having wide ranges of major oxide concentrations in comparison with meta-pelites such as SiO2 (43.48-85.51%), TiO2 (0.08-2.58%), Al2O3 (5.23-15.35%), MgO (0.11-4.67%) and CaO (0.09-9.2%) are present in Saramati Formation and as intercalations in Nimi Formation. The low values of SiO2/Al2O3 (2.22-4.78) in meta-pellites analogous to igneous rocks (3-5) indicates a lesser mature nature of the metasediments whereas meta-arenites show high values of SiO2/ Al2O3 (3.2-16.35). The high-Al meta-pellites are controlled by aluminous minerals (Biotite and clay minerals) in composition compared to meta-arenites indicating higher grade of metamorphism in Saramati formation.

In situ Rb–Sr age mapping of micas, feldspars, and clay minerals

DARWINAJI SUBARKAH[1]*, UNIVERSITY OF ADELAIDE
(darwinaji.subarkah@adelaide.edu.au)
Sarah Gilbert[2], ADELAIDE MICROSCOPY
Angus Nixon[3], UNIVERSITY OF ADELAIDE
Alan Collins[4], UNIVERSITY OF ADELAIDE
Juraj Farkas[5], UNIVERSITY OF ADELAIDE
Jarred Lloyd[6], UNIVERSITY OF ADELAIDE
Morgan Blades[7], UNIVERSITY OF ADELAIDE

Abstract

Micas, feldspars, and clay minerals are commonly found in metamorphic, igneous, and sedimentary rocks. They can also form as byproducts of potassic alteration in mineral deposits, hydrothermal systems, and fault zones. As such, dating these minerals can help constrain a number of intricate geological processes. Recent advancements in laser ablation mass spectrometer technology has allowed these K-rich (and therefore Rb-rich) phases to be dated in situ via Rb–Sr geochronology. Consequently, samples can be analysed with high spatial resolution. Nevertheless, dating these minerals can still prove to be challenging. The Rb–Sr isotopic system in K-bearing aluminosilicates can readily be disturbed by secondary processes. Notably, these perturbations can be difficult to detect through simple petrography. Another issue is a potential lack of spread between radiogenic Rb and stable Sr isotopes within the sample. These predicaments can result in mixed ages and/or large uncertainties making the method unsuccessful.

Here, we have adopted a novel approach to date micas, feldspars, and clay minerals through in situ Rb–Sr age mapping in order to address these issues. Our case study looks to test the technique by dating mica from Li-mineralized pegmatites in the Minas Gerais region of Brazil and from the Tabba Tabba pegmatite in Western Australia, feldspar and glauconite from the Ediacaran Amadeus Basin, an altered vein system from the Cambrian Delamerian Orogen and illite from a pepperite contact in the Neoproterozoic Adelaide Superbasin. Consecutive laser rasters are combined into isotopic maps where spatial and geochemical criteria can be triaged to define subdomains within the sample. These subdomains can be mm-scale and range from zones within a singular crystal or multiple generations of minerals. Pixels within these subdomains can be treated separately and pooled into analytical points which may highlight different age populations. The spread of data on an isochron can be maximized using this approach, resulting in improved precision and accuracy.

Archean continental crustal growth and reworking of the North China Craton: Constraints from zircon U-Pb age and Hf isotopic composition

Chunrong DIWU[1]*, Northwest University (diwuchunrong@nwu.edu.cn)

Abstract

Crust growth curves of the North China Craton (NCC), based on U-Pb age and Hf isotopic composition of zircons from a global database, reveal that more than 70% of the present crustal volume of the NCC had been generated by the end of the Neoarchean. The NCC nearly reached its present volume of continental crust by the Neoproterozoic. The oldest rocks, dating to ca. 3.8 Ga, have been identified in trondhjemite-dominated gneiss complexes in the Anshan and eastern Hebei areas of northeastern NCC. Hf isotopic compositions in zircons reveal that the Eoarchean continental crust in the NCC was derived from depleted mantle reservoirs. Hf isotope data in zircons from the 3.6–2.9 Ga rocks in NCC indicate that the relative proportion of juvenile material added to the crust gradually decreased during the Paleoarchean to early Mesoarchean period. Crustal reworking/recycling from older crustal reservoirs has in turn gradually dominated, with the proportion increasing from 5% to 45%. This suggests that long-term reworking of continental crust has previously occurred in the NCC during the Mesoarchean. The NCC shows relatively high net rates of continental growth during the late Mesoarchean to the end of the Neoarchean period, with at least 50–60% of the present volume of continental crust established in the time interval. Juvenile material extracted from the mantle input to continental crust has dominated in the NCC, and the proportion of newly generated crust significantly exceeds that of reworked ancient crust, with an estimated cumulative juvenile proportion over 85%. The strongly episodic distribution of U-Pb ages based on mineral systems is tightly linked to tectonothermal events of the continental crust, with peak clusters at around 2.92 Ga, 2.72 Ga, and 2.51 Ga, which is also a characteristic of crustal growth of the NCC during the late Mesoarchean to Neoarchean. The rock associations from circa 2.6–2.5 Ga were widely distributed in the NCC, occupying more than 80-90% of the Archean basement. The late Neoarchean is dominated by a large volume of juvenile material extracted from the mantle with an estimated cumulative proportion of about 85%. Meanwhile, approximately 15% of the continental crust has been reworked or recycled from older crustal reservoirs.

Updating the Cambrian Time Scale: A Bayesian approach

Valentin Jamart[1]*, Institute of Earth Sciences (ISTE), University of Lausanne, CH-1015 Lausanne, Switzerland (vjamart.phd@gmail.com)
Linda A. Hinnov[2], Atmospheric, Oceanic & Earth Sciences Department, George Mason University, 4400 University Drive Fairfax, Virginia (USA)
Damien Pas[3], Institute of Earth Sciences (ISTE), University of Lausanne, CH-1015 Lausanne, Switzerland
Allison C. Daley[4], Institute of Earth Sciences (ISTE), University of Lausanne, CH-1015 Lausanne, Switzerland

Abstract

The Cambrian Period recorded numerous fundamental events in the history of life on Earth, including the Cambrian Explosion, the Cambrian Substrate Revolution, and the onset of the Ordovician Planktonic Revolution. Despite the importance of these evolutionary milestones, a thorough understanding of the timing and driving mechanisms of these events has been impeded by relatively limited time constraints coupled with widespread endemism, leading to unclear biostratigraphic correlations among key localities.

In the Geologic Time Scale 2020 (GTS2020), the time calibration of the Cambrian Period relies on 16 radioisotope ages (Peng et al., 2020). Information about age uncertainties is not included in GTS2020 or the International Chronostratigraphic Chart v. 2023/09 (ICC 2023/09), with the exception of the Ediacaran/Cambrian and Cambrian/Ordovician boundaries. Since 2020, an additional 31 radioisotope ages and 5 cyclostratigraphic sections providing astrochronology for 15 biozones have been identified. Integrating these new age data with the existing GTS2020 and adopting a Bayesian approach for the age model substantially refines and improves the Cambrian Time Scale, and provides uncertainty estimates at all points along the time scale.

The compilation of all data into a single dataset is accomplished by assigning each of the 10 Cambrian stages a stratigraphic “thickness” of 1, starting with a value of 1 for the Ediacaran/Cambrian boundary and 11 for the Cambrian/Ordovician boundary. Biozones defined in GTS2020 are assigned fractional thicknesses within the stages. The age model for this dataset was obtained with the R package ModifiedBchron (Trayler et al., 2020), which yields an updated and improved Bayesian Cambrian Time Scale in which the stage boundaries (and any time point between boundaries) are presented with their associated uncertainties.

This new Bayesian Cambrian Time Scale aligns closely with GTS2020 and ICC 2023/09 except for the base of the Wuliuan Stage (equal to the base of the Miaolingian Series), which is approximately 3 million years younger than in GTS2020 or ICC 2023/09 (506.474±0.62 Ma vs. 509 Ma). This difference is attributed to the integration of the new radioisotope ages from Sundberg et al. (2020) and Landing et al. (2023), which are precisely located in the biozones

defining the base of the Wuliuan Stage. The new time scale also clearly identifies stratigraphic intervals with limited or no numerical age constraints, i.e., key intervals needing additional age information (e.g., the middle Fortunian to Stage 3, and Wuliuan to Jiangshanian).

PROTEROZOIC CARBONATITES IN THE SUL-RIOGRANDENSE SHIELD (SRS), SOUTH BRAZIL

Cimara Francisca MONTEIRO[1]*, Geological Survey of Brazil (cimara.monteiro@sgb.gov.br)
Ítalo Lopes de Oliveira[2], Brasília University
José Affonso Brod[3], Goiás Federal University
Érico Natal Pedro Zacchi[4], Brasília University
Carlos Eduardo Ganade[5], Brazil Geological Survey
Elton Luiz Dantas[6], Brasília University
Reinhardt Adolf Fuck[7], Brasília University

Abstract

The SRS, located in southern Brazil, was formed during the Brasiliano orogeny from the closure of the Charrua ocean (900-680 Ma), followed by a collision between the Rio de la Plata and Kalahari cratons, marked by granitogenesis, volcanism and sediment deposition at the end of the orogenesis (650-550 Ma) (Chemale Jr., 2000; Hartmann et al., 2008). Seven carbonatite intrusions were identified within the SRS, the first discovery being made in 2010. In terms of degree of deformation and texture, it is possible to separate these intrusions into at least two groups: foliated carbonatites with the occurrence of gneiss banding and non-foliated carbonatites or with incipient foliation (Bogo, 2020). This study has as its main object the four intrusions that were part of the deformed carbonatites, namely Três Estradas, Santa Clara, Picada dos Tocos and Passo Feio, which present similar textural, mineralogical and geochemical features. The remaining ones, Joca Tavares, Santa Inês and Porteira exhibit similar characteristics and weak or incipient deformation. The Três Estradas and Santa Clara metacarbonatites are contiguous and approximately 4 km apart. Both have a linear shape along the NE direction with a preferential subvertical dip to the NW and intrude paleoproterozoic/archaean rocks from the Santa Maria-Chico complex, in the Taquarembó terrane, in the vicinity of the Ibaré lineament, on the northeaster limit of the Rio de la Plata Craton. They range from incipient foliation to gneiss banding with alternating bands of biotite and actinolite and bands calcitic, containing dolomite and apatite, and are metamorphosed into greenschist to amphibolite facies. Age estimates obtained by U/Pb in zircon (Monteiro et al., 2020) in the Três Estradas metacarbonatites provide 1,110±4.8Ma, considered coherent for the Santa Clara body as well, although it does not have specific age estimations yet. The Picada dos Tocos and Passo Feio carbonatites, 12 km a part, are located in the Passo Feio complex inside of the São Gabriel terrane and both bear Neoproterozoic ages. Despite laying 140km northeast of the Três Estradas and Santa Clara bodies, they exhibit textural, mineralogical, geochemical features and types of deformation similar to the latter two. The Picada dos Tocos intrusion was dated at 603.2±4.5Ma using U/Pb in zircon (Cerva-Alves et al., 2017). It is estimated that neighbouring Passo Feio intrusion presents this same age. Based on the Sm/Nd, Sr/Sr, Lu/Hf isotopic signatures of Três Estradas (Monteiro et al., 2020), the different intrusion ages and similar geochemical signatures among the Três Estradas (Bogo, 2020), Picada dos Tocos (Cerva-Alves et al., 2017) and Passo Feio (Morales et al., 2019) bodies, it is possible to suggest that carbonatite magmatism

occurred in pulses over time, and that these intrusions, subjected to similar petrogenetic processes, were originated from the melting of the same asthenospheric mantle enriched with REE (Monteiro et al., 2020).

Abstract

Iron formations are geological records exclusive to the Precambrian era and hold significance not only in economic terms, associated with vast iron deposits, but also as valuable geochemical and paleoenvironmental archives. Despite their significance, the mechanisms driving their formation remain unclear, primarily due to the absence of modern analogues. This study delves into the temporal aspects of Fe- and Si-layer genesis through a multiscale rheological approach. Our investigation focus on from the ice-rafted debris-bearing iron formation samples from the Brazil's Cryogenian Banda Alta Formation (Urucum District). This geological context provides an instructive example for this research, due to its persistent parallel laminations and minimum post-depositional thermal influence. Employing macroscopic, microscopic, and crystallographic analyses (Raman and EBSD methodologies), we explore two hypotheses: a depositional and a diagenetic origin for the layer alternations. Examination of impact structures beneath clasts in both macro and microscopic analyses reveals deviation and deformation of the expected parallel lamination, suggesting discernible layering predating clast impacts. This challenges the proposed diagenetic layering formation, which posits a homogeneous Fe-Si gel coprecipitation mechanism with band separation during diagenesis. Exploring the depositional hypothesis, we identify two possibilities: separated compositional precipitation or a greenalite-rich proto-layering mechanism. To discuss the latter, we question whether the estimated depositional timeframe allows sufficient time for diagenesis to achieve proper layering through silica cementation and to imprint syndepositional ice-rafted debris deformation. Considering these findings, we argue for a primary alternating iron and silica depositions as the most plausible depositional mechanism for iron formation genesis.

Patrícia Moreira[4], Fundação/Universidade Fernando Pessoa, Portugal; MARE - Centro de Ciência do Mar e Ambiente/URI Coimbra, Portugal
Cristina F.A. Rodrigues[5], Academia das Ciências de Lisboa, Portugal; Fundação/Universidade Fernando Pessoa, Portugal; MARE - Centro de Ciência do Mar e Ambiente/URI Coimbra, Portugal
Ana Salgado[6], Academia das Ciências de Lisboa, Portugal; CLUNL - Centro de Linguística da Universidade NOVA de Lisboa, Portugal

Abstract

The Academy of Sciences of Lisbon conducted an extensive study to establish an updated Portuguese (PT) terminology for chronostratigraphic/geochronologic units of selected Geological Timetables.

The study, coordinated by M.J. Lemos de Sousa and Ana Salgado, was developed by a joint task force between the Earth and Space Sciences section of the Class of Sciences and the Institute of Lexicology and Lexicography of the Academy.

In addition to establishing an updated terminology in the subdomain of Stratigraphy, the study should also be regarded as a valuable contribution to the Academy’s newly developed Dictionary and Vocabulary, which is currently available online.

In pursuit of this objective, the authors considered the mandatory rules of both the International Stratigraphic Guide (Salvador 1994, reapproved 2013), and the erudite norm of the Portuguese language variety.

The following Geological Timetables were considered in the study:

• International Geological Timetable, usually referred to as the “standard” or “global” table, published by the International Union of Geological Sciences/International Commission on Stratigraphy as the “International Chronostratigraphic Chart”.

• Detailed Geological Timetable of the Quaternary, traditionally considered as a complementary chart of the global one.

• Geologic Timetable of the Bohemo-Iberian Ordovician regional chronostratigraphic units, specifically needed for the classification of Portuguese Ordovician units.

• Geologic Timetable of the West European Carboniferous regional chronostratigraphic units, specifically needed for the classification of Iberian terrestrial Carboniferous units.

In this poster, the authors present the “International Chronostratigraphic Chart” in both English

and its corresponding new version in Portuguese (PT). In cases where linguistic rules allowed for the validation of various Portuguese orthographic variants, the variant used in the general table corresponds to the preferred form.

Note: The coordinators and other authors have been listed alphabetically on purpose, as each has contributed an equal amount of time and expertise in the development of the present research.

Study on high-precision sequence stratigraphic characteristics and lake level variation trend: A case study of the lower part of the fourth Member of the Paleogene Shahejie Formation (Es4x) in the Niuzhuang Sub-sag

Zhaoxiang CHEN[1]*, China University of Petroleum (East China) (1132349254@qq.com)
Yanzhong Wang[2], 18253266698
Yingchang Cao[3], 18243526548
Rongkun Li[4], 17682506984

Abstract

Through exploration and development, Es4x in the Niuzhuang Sub-sag is primarily composed of reddish-toned clastic deposits formed in a continental depositional environment, commonly known as the red bed. However, the period of red bed formation was unfavorable for biological survival, resulting in a scarcity of fossil remains and unstable lithology, which poses significant challenges for traditional biostratigraphic and lithostratigraphic classification methods. This, in turn, has hampered the progress of deep oil and gas exploration efforts in the region. Therefore, the focus of this study is on the high-resolution sequence stratigraphic division of Es4x in the Niuzhuang Sub-sag, aiming to provide geological evidence for oil and gas exploration and development. Guided by the theoretical frameworks of the Vail sequence stratigraphy and Cross's high-resolution sequence stratigraphy, this study comprehensively utilizes a range of data, including 3D seismic data, drilling core samples, well logging data, and well testing data, through techniques such as well logging wavelet transformation, stratigraphic stacking patterns, and Δlog(R) analysis, the study successfully identifies the top and bottom interfaces, T7x and T7, of the third-order sequence within Es4x in the Niuzhuang Sub-sag. Within this framework, two fourth-order sequences and nine fifth-order sequences are further delineated. The results indicate that the overall sedimentary strata of Es4x are relatively thin, with the thickness varying gradually from south to north and from east to west. The fourth-order sequence interfaces within Es4x gradually overlie the base interface towards the south and approach the top interface towards the east, potentially culminating in truncation or overlap onto the top interface. The fifth-order sequence T7w-1 gradually disappears towards the south, while T7w-4 disappears towards the east. The fifth-order sequence T7w-9 is only present in certain regions of the central and western parts of the study area. Based on the analysis of the third-order sequence, it is observed that during the initial stages of deposition in Es4x, the lake level was on a rising trend, peaking during the fifth-order sequence T7w-3, when the maximum lake flooding surface was reached. Subsequently, the lake level began to decline, a trend that persisted until the deposition of Es4x came to an end. On the other hand, when considering the fourth-order sequences, the lake level initially rose, peaked during the T7w-3 period, and then declined. It subsequently rose again during the T7w-5 period and began to decline during the T7w-6 period, persisting until the boundary of that particular fourth-order sequence. This study holds positive implications for subsequent research on deposition and exploration in Es4x in the Niuzhuang Sub-sag. It also serves as a valuable

reference for sequence stratigraphic classification in similar strata in other regions.

Abstract

The conversion of basaltic crust into a thick, buoyant felsic crust of tonalite-trondhjemite-granodiorite (TTG) composition has been a fundamental process in the Earth's evolution during the Archaean Eon (4.0–2.5 Ga). The proposition that TTGs have formed because of melting of hydrated mafic rocks is now well established by geochemical modelling and experimental methods, although these processes have only rarely been tested or documented by field studies. Here, we investigate the migmatite structures and major and trace element geochemistry of the Neoarchaean Lake Inari TTG-amphibolite terrain in northern Finland, in the Lapland-Kola Province of Arctic Fennoscandia. The Lake Inari amphibolites comprise basalts that have flat or slightly LREE-enriched REE patterns, geochemically resembling younger flood basalts. The TTGs have two coeval and intermingled geochemical endmembers, namely low- and high-HREE types, which differ in their garnet-compatible trace element abundances (HREE, Mg, Sc, Y, Co, and Zn), which is attributed to the presence or absence of garnet in their respective sources. The TTG-metabasalt association shows various migmatite structures such as metatexites, metatexite-diatexite transitions and massive diatexites that have formed in response to weakening of the crust, melt SEMR (Segregation, Extraction, Migration, and Redistribution) processes, and syn-anatectic strain. The Lake Inari terrain was a melt-rich crustal horizon with widespread migmatization instigated by partial melting of a basaltic plateau generated over a mantle plume, consistent with a stagnant to sluggish lid tectonic setting for their formation. The Lake Inari terrain formed by migmatization of a basaltic source. Overall, the present denudation level of the terrain mostly corresponds to the metatexite-diatexite transition and diatexite zones. Plateau basalts were converted to buoyant TTGs through mid-crustal migmatization that set off the evolution of continents.

Abstract

In Ecuador, the tectonic evolution of the Subandean zone has sparked interest from both academia and industry due to the region's economic potential. Several authors have devoted their efforts to characterizing the area's lithostratigraphy, which includes a crystalline basement covered by mega-sequences of volcanic, volcaniclastic, and sedimentary rocks spanning from the Carboniferous to the Quaternary.

The Upper Cretaceous sedimentary mega-sequence of the Oriente Basin, composed of the Hollín, Napo, and Tena formations, has been extensively studied due to its economic significance in the petroleum industry. However, the lack of information about the petrographic and geochemical characteristics of the source rocks of the Tena Formation in the central and southern Subandean zone has created uncertainty in the regional geological evolution model, particularly in the Maastrichtian to Paleocene interval. The Anzu River section, northwest of Puyo, provides the opportunity to analyze the provenance of the Tena Formation, exposing its stratigraphic sequence comprehensively and continuously. This research details the lithostratigraphy, petrography, geochemistry, heavy mineral assemblages, and U-Pb ages in detrital zircons of the Tena Formation in the Anzu River section to define the detrital source of the Tena Formation. Petrographic analysis reveals that the sandstones of the Tena Formation consist of feldspathic litharenites, lithic arkoses, and sublitharenites, originating from sources rich in quartz and mixing zones. Heavy mineral assemblages and concentrations of major oxides, trace elements, and rare earth elements indicate that these sandstones are sourced from recycled sedimentary provinces and felsic igneous provinces deposited on a passive margin. U-Pb ages in detrital zircons show a major U-Pb age concentration at 1550–1300 Ma (Rondonian-San Ignacio) and subsidiary peaks in 1800–1550 Ma (Rio Negro Juruena) and 1300–900 Ma (Sunsás); additionally, a peak age is observed at 110 - 70 Ma (Andes). These sources would be linked to Andean regions that assimilated blocks or tectonic wedges from the Oriente Basin during orogeny, where the erosion of these blocks has controlled the available detritus for the sedimentation of the Tena Formation in the study area.

LYNDON NAWANAO[6], University of the Philippines

Abstract

In this study, we investigate the geology of northern Luzon and the geomorphological evidence associated with the active deformation and development of the three stratigraphic terranes in the region: Ilocos Basin, Central Cordillera (CC), and Cagayan Valley Basin (CVB). From Ilocos Sur on the west to Kalinga on the east, ten geological formations ranging from Cretaceous to Quaternary were recognized. 1) The Cretaceous to Eocene Pugo Formation serves as the basement unit of CC and consists of jointed, columnar, and massive andesite and andesite porphyry. 2) The Eocene Abuan Formation forms the basement unit of the CVB and consists of basalt and porphyritic andesite with epidote and plagioclase phenocrysts. 3) The Early Oligocene Dibuluan Formation which unconformably overlies the Abuan Formation, consists of massive pyroclastic deposits and agglomerates with clasts of andesite, gabbro, and diorite. 4) The Late Oligocene to Early Miocene Zigzag Formation, overlying the Pugo Formation, consists of interbedded indurated mudstone and sandstone that are intercalated with tuffaceous clastics. 5) The Late Oligocene to Middle Miocene Central Cordillera Diorite Complex (CCDC), which intruded both the Pugo and Zigzag formations consists mainly of diorite and andesite porphyry. 6) The Late Oligocene to Early Miocene Lubuagan Formation that unconformably overlies the Dibuluan Formation is composed of steeply dipping and highly deformed interbedded sandstone and mudstone. 7) The Late Middle Miocene to Late Miocene Batac Formation consists of a thick sequence of interbedded fissile mudstone and lithic sandstone. 8) The Late Pliocene to Early Pleistocene Ilagan Formation that conformably overlies the Lubuagan Formation is composed of interbedded sandstone, mudstone, and conglomerate with fossils of leaves, ferns, and mollusks. 9) The Early Pliocene to Pleistocene Laoag Formation is distinctly composed of reefal limestone, fossiliferous sandstone, and conglomerate. 10) The Middle to Late Pleistocene Awiden Mesa Formation, which consists of dacitic welded tuffs, tuffaceous clastics, and indurated lahar deposits, unconformably overlie the Ilagan Formation. Faults, lineaments, offset streams, and other geomorphic features, including the Tabuk Plateau and Pangul Anticline, were delineated using red-relief image maps (RRIM). The Tabuk Plateau consists of pyroclastic and fluvial sediments that were deposited along the footslopes of the Central Cordillera. The Pangul Anticline, which forms part of the CVB anticlinal belt, is characterized by overturned folds caused by oversteepening and accelerated uplift. Lineaments are generally NW trending, while the

majority of the faults are strike-slip as inferred from offset streams. These geological units, along with the delineated geomorphological features, provide additional insights into the geotectonic development and deformation of northern Luzon during the Cenozoic.

New data on the stratigraphy of the Middle and Upper Jurassic strata of northeastern Iran

Niki MAJIDIFARD[1]*, Student of the University of Science and Technology (nikimajidifard.mfa@gmail.com)
MAHMOUDREZA MAJIDIFARD[2], Research Institute for Earth Sciences in Geological Survey of Iran

Abstract

The Middle and Upper Jurassic rocks of the Alborz Mts. (northern Iran) and Koppeh Dagh (northeastern Iran) are chiefly represented by the Shal, Dalichai, Lar, Bashkalateh, Kashafrud, Chaman Bid and Mozduran formations. They are distributed over a large area and reach a maximum thickness of nearly 1600 m at the type locality of the Chaman Bid Formation . In North Iran, the Jurassic system consists of two distinct Sedimentary- Tectonic megacycles. The first started after the closure of the Palaeo-Tethys (in the Late Triassic). From the early Norian onward, widespread transgression of the Shemshak sea led to deposition of siliciclastic rocks of the Shemshak Group (Norian-Middle Bajocian). This cycle ended in the early Bajocian with the Mid-Cimmerian tectonic event. The second megacycle began in the late Bajocian. The transgression gave rise to an epicontinental sea subdivided into basinal and platform area in north-central and north-eastern Iran. This situation continued into the Cretaceous when, in the Neocomian, the Late Cimmerian tectonic event terminated the second sedimentary cycle. The similarity of the sediments and faunas with those of the same age in Afghanistan and Armenia indicates that north and central Iran were situated at the southern margin of Laurasia. The second sedimentary megacycle consists mostly of marl and limestones Dalichai Formation (= Chaman Bid Formation of earlier authors) and limestones (Lar Formation, Mozduran Formation) indicative of basinal and carbonate platform environments. These sediments began to form from the end of the Mid Cimmerian tectonic phase until the Late Jurassic and in some place continued into the “Neocomian”. For example, in some areas of the Alborz and Koppeh-Dagh, the same style of sedimentation continued from the Late Jurassic (Tithonian) to the Early Cretaceous (Berriasian). At some localities, such as Minodasht, Firouzkouh and Jam the sedimentary basin was not only deep but also pelagic in nature. Therefore, the Middle and Upper Jurassic rocks of northeastern Iran consist seven formations; Dalichai, Lar and Shal (Alborz) and Chaman Bid, Mozduran, Kashafrud, and Bash Kalateh (Koppeh Dagh). However there is no difference with respect to lithology and depositional environment between the Dalichai, Chaman Bid and Shal formations, nor between the Lar and Mozduran formations or between the Bashkalateh and Kashafrud formations. For this reason it is proposed to discontinue the usage of the lithostratigraphic terms Shal Formation, Chaman Bid Formation, Mozduran Formation, and Bashkalateh Formation.
Based on ammonites, the Dalichai Formation is strongly diachronous: If many strata in the Upper Bajocian until the Late Jurassic. The Lar Formation ranges from the Oxfordian to the Neocomian, the Shal Formation from the Late Bajocian to the Neocomian and the Kashafrud Formation from

the Late Bajocian to the Late Bathonian.

New insight into crustal exhumation induced by granitic intrusion following intracontinental contractional deformation: a possible model for Hohhot thermal upwelling-extensional structure, Inner Mongolia, north China

Yu ZHANG[1]*, Chinese Academy of Geological Sciences (yuzhang000@126.com)
Shuwen Dong[2], Chinese Academy of Geological Sciences
Wei Shi[3], Chinese Academy of Geological Sciences

Abstract

Contemporaneous A-type granites, mylonitic shear zones, and low-angle normal faults are the first-order features of the “metamorphic core complexes (MCC)” in the North China Craton (NCC). Strongly deformed middle-lower crustal rocks exposed in the ancient orogenic belt of NCC, whether these rocks were exhumed via diapiric upwelling or low-angle detachment faulting is debated. The Hohhot “MCC”, located at north NCC, records top-to-southeast normal-sense exhumation of the deformed Archean-Proterozoic metamorphic basement that was intruded by Jurassic-Cretaceous complex granite mass. We conducted geological mapping of the Hohhot extensional structures, with integrated structural, the quartz lattice preferred orientation (LPO), geochemical, and thermo-/geochronological analyses to characterize the geometry and kinematics of extension and exhumation of the mylonitized footwall. The basement was intruded by deformed Jurassic adakitic and undeformed Cretaceous A-type intrusions in the footwall. The mylonitic shear zone (S1) located between undeformed Cretaceous granite and low-angle detachment faults was separated from the doming system, characterized by pervasively top-to-SE simple shearing (ca. 146–141 Ma). Based on this, we defined the three units composed Hohhot “MCC” and reestablished Hohhot thermal upwelling-extensional structure (TUES) model: (a) the core-granite composed of Early Cretaceous (136–127 Ma) A-type granites; (b) the pure-shear-dominated shear zone (S21) distributed in the core-granite periphery, with foliation (no lineation), characterized by high-temperature (>500℃) deformation; (c) the low-angle detachment system (S22) characterized by low-angle normal faults separating the footwall top-to-the-SE ductile structures and microbreccia zone from the hanging-wall Cretaceous supra-detachment basin along the flank of domal S1, with the deformation temperature decreasing from high-temperature (>500℃) to low temperature (ca. 300°C) as away from the core-granite, characterized by simple shear sense. We propose that the Early Cretaceous mantle-derived magmatism led to coeval diapiric upwelling of the lower crust, exhumated the footwall, and overprinted previous compressional structures with the generation of pure shear zone and low-angle detachment system. Therefore, the exhumation of footwall rocks of Hohhot TUES was not driven by low-angle detachment faulting.

Late Cretaceous rapid uplift and denudation of northern Tibet and its climatic effects

Hao WU[1]*, Guilin University of Technology (wuhaojlu@126.com)

Abstract

The Tibetan Plateau is the broadest and highest elevated surface on Earth and is thought to have formed in response to the collision between India and Asia during the Cenozoic. Formation of the plateau had a significant effect on Asian climate and may have been responsible for gradual cooling of the global climate. However, an increasing number of studies have suggested that growth of the Tibetan Plateau was a complex process due to a series of accretionary events involving several Gondwana-derived terranes in Asia that began in northern Tibet during the Mesozoic. These pre-Cenozoic subduction and collision events provided favorable preconditions for the formation of a proto-plateau prior to the India–Asia collision. Therefore, any hypotheses involving the formation of the modern Tibetan Plateau during the Cenozoic should include the Mesozoic contribution to crustal thickness and topographic relief.

We present a combined geochronological and geochemical study of terrestrial molasse deposits and interlayered volcanic rocks in northern Tibet that, along with regional geological data, reveal that rapid uplift and denudation occurred during the Late Cretaceous (105–75 Ma) and formed the p-TP. We propose that this rapid uplift event was a result of isostatic rebound in response to post-collisional lithospheric foundering, which was controlled mainly by the nature of the overthickened lithosphere beneath the Lhasa–Qiangtang collisional zone. Provenance analysis of the molasse sediments defines a newly revised paleo-topographical framework for the collisional zone, which reached a high elevation (~4000 m) with a narrow Bangong–Nujiang paleo-valley (<2000 m) inside the suture zone. This Late Cretaceous uplift-related erosion contributed to lower atmospheric pCO2 levels, which probably caused global cooling.

When did the Mongol-Okhotsk Ocean close?

Zhiyu YI[1]*, SUN YAT-SEN UNIVERSITY (yizhy5@mail.sysu.edu.cn)
Yushu Liu[2], SUN YAT-SEN UNIVERSITY
Yongqing Liu[3], Institute of Geology, Chinese Academy of Geological Sciences
Joseph Meert[4], University of Florida
Pengfei Wang[5], SUN YAT-SEN UNIVERSITY

Abstract

The Mongol-Okhotsk Ocean (MOO) suture, which separates the Siberia Craton to the north and North China-Amuria Block to the south, play a critical role in understanding the Mesozoic tectonics of East Asia. However, there exists a significant discrepancy between the timing of MOO closure based on paleomagnetic data and geological evidence, ranging from the Late Triassic to Early Cretaceous. We analyze paleomagnetic data from Mongolia, Siberia and North China, incorporating a refined geochronology for the key Siberian poles, we argue that previously published apparent polar wander paths (APWPs) for North China and Siberia are insufficient to precisely constrain the timing of MOO closure. We present a set of high-quality paleomagnetic poles derived from the late Triassic and Jurassic igneous rocks (including lavas, dykes and sills) from the North China craton in an effort to refine the timing of the MOO closure. The late Jurassic pole, obtained from volcanic rocks of the Tiaojishan Formation (at 51 sites), indicates a paleolatitude of 36.6 ± 5.1° N for North China during ~152-161 Ma, using Beijing as the reference site. The late Jurassic pole, derived from dykes and sills intruding the Nandaling Formation (at 19 sites), defines a paleolatitude of 36.8 ± 7.4° N for North China at 155 ± 3.4 Ma, which is in agreement with that derived from the Tiaojishan Formation. The middle Jurassic pole, based on volcanic lavas of the Nandaling Formation (24 sites), places North China at ~61.7 ± 9.1° N during ~168-180 Ma. The late Triassic paleopole, obtained from dykes and sills, positions North China at 75.6° ± 6.8° N at ~220 Ma. The paleogeographic reconstructions, based on the new poles and the updated global APWPs, support the idea that the North China-Amuria Block and Siberia had already amalgamated prior to ~220 Ma. In contrast, our reconstruction conflicts with previous interpretations based on paleomagnetic evidence, which predominantly suggest a late Jurassic-early Cretaceous closure of the MOO. Furthermore, the late Triassic (~220 Ma) reconstruction implies that the East Asian blocks were already part of Pangea long before its eventual break-up at ~170 Ma, indicating that Pangea comprises ~99% of available continental crust and was perhaps the largest of all known supercontinents.

Extensional Tectonics and North China Craton Destruction — insights from the Magnetic Susceptibility Anisotropy (AMS) of granite and Metamorphic Core Complex

Wei LIN[1]*, State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences (linwei@mail.iggcas.ac.cn)
Lingtong Meng[2], State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

The craton is long-lived and stable on the Earth surface. However, since the Mesozoic, the North China Craton (NCC) was characterized by large-scale lithospheric removal, the fundamental change of physical and chemical characteristics of the lithospheric mantle, widely distributed crustal deformation, and extensive magmatism. This complex evolution contrary to other cratons has been called the NCC destruction. The widespread magmatism in the eastern NCC was an important response to the lithospheric removal in-depth and crustal deformation on the surface geology. The plutons were emplaced under a tectonic context and therefore recorded the information of the tectonics, especially, the Magnetic Susceptibility Anisotropy (AMS) pattern of the pluton which was acquired with the influence of regional stress. In the past fifteen years, about 22 plutons, intruding during the different periods from the Late Triassic to the late stage of the Early Cretaceous, have been studied with AMS. The emplacement mechanism of plutons, and the contemporary tectonic setting were discussed to constrain their relationship with the NCC destruction in different stages of magmatism. As a result, the Late Triassic, Early Jurassic, and Late Jurassic plutons exhibit consistent N(E)-S(W) trending magnetic lineation. The early stage of Early Cretaceous plutons displays NW-SE trending magnetic lineation while the late stage of Early Cretaceous plutons shows magnetic lineation with various orientations. Combined with the previous studies, it is concluded that the emplacement of the plutons, intruding in the three stages were controlled by the weak N(E)-S(W) orientated extension, regional NW-SE trending extension, and a weak extension in the shallow, respectively. The transformation of regional extension from the N(E)-S(W) to the NW-SE direction was accompanied by a strain-increasing tendency. The extensional tectonics in the eastern NCC was interpreted to represent the interaction between the Mongol-Okhotsk belt, the Paleo-Pacific plate, and eastern Eurasian continent.

The Central Asian fold belt (CAOB): granite domes of the Erguna Massif as indicator of Mesozoic extension (evidence from the Trans-Baikal geotransect and parametric borehole of 2 600 m depth)

Ivan KUDRIAVTCEV[1]*, VSEGEI (ivan_kudryavtsev@yahoo.com)
Juliia Golysheva[2], VSEGEI

Abstract

The Trans-Baikal geotransect crosses fold framing of the Siberian Craton, including Erguna Massif of CAOB, south of the Mongol–Okhotsk suture zone. Due to geophysical data several dome structures were distinguished within the Erguna Massif, on the surface these structures are presented by granites domes.

The nearest to the Mongol–Okhotsk suture Borshchovochnyi dome, having features of metamorphic core complex, was drilled by the Trans-Baikal parametric borehole of 2 600 m depth. The objective of this borehole was to study the geological nature of the dome structure and to obtain the parametric information on the section based on study of the sampled core and the results of geological and geophysical studies of the borehole. The uniqueness of this project is that the metamorphic core complex as the target for deep geophysical data verification by deep drilling was never before.

Metamorphic core complexes belts have been identified and studied in Northern Mongolia and the Trans-Baikal region where it's traced at a distance of more than 900 km. These processes recorded the global intracontinental extension in the Asian region during the Early Cretaceous.

The borehole section is characterized by continuous core sampling, a wide range of geophysical surveys in the borehole (logging), and analytical studies of the rock's samples. Within the section three main structural elements of metamorphic core complexe were identified: the upper plate, detachment, and the lower plate. The upper plate (slightly metamorphosed rocks) is represented by a serpentinite mélange separated from the underlying rocks of the lower plate by a zone of chlorite breccias (detachment). The lower plate comprises of granites, schists and plagiogneisses. The upper part of the lower plate is composed of mafic and intermediate schists with amphibolites and quartzites. Biotite granite is widespread in the section as layered veins with synkinematic signs, the age of biotite granite is about 130 Ma. Schists are characterized by a mylonite structures at intervals of interbedding with biotite granites. The geophysical logging data and the petrophysical characteristics of cored rocks confirms that the mylonite zone is the provenance of a series of inclined reflectors in the seismic section, which can be traced to a depth of at least 10 km.

Below the schists the section is composed of plagiogneisses, leucogranites and gneissic granites. The protolith of plagiogneisses is monzodiorite-granite series of Permian-Triassic age. The age of amphibolite facies metamorphism is about 140-150 Ma. The Borshchovochnyi dome sections demonstrates signs of the cordilleran metamorphic core complex, which was formed due to crust detachment evolution as the result of extension.

The other domes within the geotransect are characterized by similar morphology. According to the

geophysical data these structures are also related to detachments having a northern dip. All identified detachments are connected with the crust basal detachment on the 15-20 km depth. The detachments and domes system are the indicator of the global extension, which reworked the Erguna Massif crust.

Decoding the link between magmatic cyclicity and episodic extensional and contractional tectonics: insights from the Late Mesozoic granites of the eastern China

Lingtong MENG[1]*, State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences (tone18@mail.iggcas.ac.cn)
Wei Lin[2], State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences
Yang Chu[3], State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

The cyclical change in subduction style is the favorable mechanism to elucidate the cyclicity of continental arc magmatism, however, the role of episodic tectonics and variation of the lithosphere in overriding plates is much underestimated. Here we focus on the Late Jurassic to Early Cretaceous granites related to Paleo-Pacific Ocean subduction in the Jiaodong Peninsula, eastern China. Based on our structural analysis, magnetic fabric measurement, and gravity modeling, polyphase deformation and magma emplacement have been recognized within the Late Mesozoic granites.

Late Jurassic (160-150 Ma) NE-SW extension was expressed by a high-temperature, top-to-the-NE normal shearing. Accompanied by this extension, the Late Jurassic granite has concentric magnetic foliations with NE-SW magnetic lineations, and several NW-SE trending feeder zones at depth. The Latest Jurassic-Earliest Cretaceous (150-135 Ma) NE-SW contraction resulted in a lower-temperature, top-to-the-SW ductile shearing with magmatic lulls. Early Cretaceous (130-120 Ma) NW-SE extension is characterized by detachment faults with either top-to-the-SE or top-to-the-NW kinematics around the Late Jurassic granites, leading to their exhumations. Meanwhile, the Early Cretaceous (130-120 Ma) granite is “syn-kinematic”, which has NW-SE mineral/magnetic lineations, top-to-the-NW kinematics, and wedge-shaped geometry at depth. Finally, with the space opened by regional extension, isotropic pluton is permissively emplaced at the upper crust during the late stage of the Early Cretaceous (120-110 Ma).

By summarizing previous geological records and our new data, we build the feedback mechanism among magmatic cyclicity and episodic tectonics in the overriding plate. We show that (a) the magmatic flare-ups correspond to extensional tectonics, while the magmatic lulls are coeval with regional contraction; (b) a multi-feeder model of granite emplacement is dominated at the Late Jurassic weak extension, while changes to extensional structure controlling at the Early Cretaceous intensive extension; (c) with the increasing regional extension of the overriding plate, the magmatic flux is enhanced. Our model emphasizes episodic the deformation of the lithosphere and associated crustal thickness variation in controlling magma production, which may shed new light on understanding the magmatic cyclicity under continuous subduction.

The Lateral Accretionary Orogenic Process at Pangea's Conveyable Zone: Insights from the Borneo's Oldest Granitoids in Southeast Asia

Shan Li[1]*, University of Chinese Academy of Sciences (lishan@ucas.ac.cn)
Long Xiang Quek[2], University of Chinese Academy of Sciences

Abstract

Pangea stands as the last known supercontinent of the Phanerozoic era, its gradual reorganization around 250 Ma ultimately leading to the formation of the present-day continental edifices. Our research delves into the emergence of juvenile magmatism in tandem with autochthonous orogenesis, which challenges allochthonous ancient blocks across the Tethyan Realm—the only conveyable zone of Pangea. Our investigation centers on the oldest (Permo-Triassic) granitoids in Borneo, once considered ancient basement rocks. The Permian-Triassic granitoids from West Malaya, East Malaya, Bangka-Belitung, and Sumatra show ilmenite series granitoids, owing to contributions from recycled sediments related to the Tethys system, whereas North Borneo shows magnetite series granitoids related to the Paleo-Pacific system. However, the geochemical patterns of West Borneo Permian-Triassic granitoids seem to show superimposed imprinting in both systems. Our comprehensive analyses of geochemical data in southeast Tethyside, reveal contrasting (ancient vs. juvenile) sources for Borneo Permian-Triassic granitoids. Importantly, this study finds two distinctive periods of juvenile additions at ~240 Ma and ~210 Ma, characterized by positive zircon εHf(t) values and mantle-like zircon δ18O values. These findings provide crucial evidence for the initiation of juvenile magmatic "flare-up" events and the crustal growth in the Triassic during Pangea's reorganization. A combination of the sideway drift towards Pangea's subduction girdle and heat release from Pangean Eurasia during Sibumasu's final approach at ~240 Ma may have caused the Paleo-Pacific subduction system to retreat, contributing to the autochthonous growth of the southeast Tethyside edge. The later juvenile addition at ~210 Ma may not originate from the Paleo-Pacific system, as it is conceivable that Neo-Tethys subduction-induced magmatic "flare-ups" with zircon εHf(t) values in Sumatra could extend their influence to Borneo. This study sheds new light on the Borneo continent that hosts much of the juvenile crust added to the Pangean Eurasia continents since the Triassic via accretionary orogenesis. This study thus substantiates the central role of accretionary orogens in making and shaping southeast Tethyside continents.

Middle-Late Jurassic crustal shortening in the central–western North China craton in response to multi-plate convergence in the East Asia

Wei SHI[1]*, Chinese Academy of Geological Sciences (shiweinmg@163.com)
Shuwen Dong[2], SinoProbe Lab, Chinese Academy of Geological Sciences
Yueqiao Zhang[3], Nanjing University

Abstract

The Jurassic multi-plate convergence in East Asia led to the intra-continental deformation in the North China craton. However, much controversy is highlighted in the intra-continental deformation style and timing, and unanimous kinematics. The central–western North China craton is marked by the Ordos block surrounded by a number of Mesozoic structural belts, containing Lvliangshan–Taihangshan belt to the east, Yinshan belt to the north, Helanshan–Liupanshan belt to the north, and by Jurassic basins grow in the structural belts, comprising Ningwu–Jingle, Yungang basins in the Lvliangshan belt, Shiguai basin in the Yinshan belt, Ruqigou, Tujuan basins in Helanshan belt, recording inter-continental deformation due to multi-plate convergence in East Asia. Here, using new structural analysis, the definition of Jurassic growth strata, and paleo-stress inversion, grouping with our previous work on the North China craton, we reconstructed a multi-directional shortening pattern in the central–western North China craton during the Middle–Late Jurassic (170–160 Ma), which is characterized by N–S shortening along the northern margin of the North China craton, by NW–SE shortening in the western margin and along the central zone of the North China craton. In combination with regional structural analysis, we propose that the central–western North China craton is roughly situated at the center of the multi-plate convergence during the Middle–Late Jurassic, and the southward compression was caused by the closing of the Mongolia–Okhotsk Ocean in the north, the northwestward compression by the subduction of paleo-Pacific plate beneath the East Asia continent in the east, and southeastward compression by the closure of the Meso-Tethys in the west.

Gondwanan Flood Basalts Linked Seismically to Plume-Induced Lithosphere Instability

Yanan SHI[1]*, Southern University of Science and Technology (shiyn@sustech.edu.cn)
Jason Morgan[2], Southern University of Science and Technology

Abstract

Delamination of continental lithospheric mantle is well-recorded beneath several continents. However, the fate of the removed continental lithosphere has been rarely noted, unlike subducted slabs reasonably well imaged in the upper and mid mantle. Beneath former Gondwana, recent seismic tomographic models indicate the presence of at least 5 horizontal fast-wavespeed anomalies at ~600 km depths that do not appear to be related to slab subduction, including fast structures in locations consistent with delamination associated with the Paraná Flood Basalt event at ~134 Ma and the Deccan Traps event at ~66 Ma. These fast-wavespeed anomalies often lie above broad slow seismic wavespeed trunks at 500-700 km depths beneath former Gondwana, with the slow wavespeed anomalies branching around them. Numerical experiments indicate that delaminated lithosphere tends to stagnate in the transition zone and mid-mantle above a mantle plume where it shapes subsequent plume upwelling. For hot plumes, the melt volume generated during plume-influenced delamination can easily reach ~2-4×106 km3, consistent with the basalt eruption volume at the Deccan Traps. This seismic and numerical evidence suggests that observed high wavespeed mid-mantle anomalies beneath the locations of former flood basalts are delaminated fragments of former continental lithosphere, and that lithospheric delamination events in the presence of subcontinental plumes induced several of the continental flood basalts associated with the multiple breakup stages of Gondwanaland. Continued upwelling in these plumes can also have entrained subcontinental lithosphere in the mid-mantle to bring its distinctive geochemical signal to the modern mid-ocean spreading centers that surround southern and western Africa.

Late Jurassic true polar event revealed by paleomagnetic study in North China and its implication for regional tectonics and biota evolution in East Asia

Yifei Hou[1], Insititute of geology and geophysics, Chinese Academy of Sciences
PAN ZHAO[2]*, Insititute of geology and geophysics, Chinese Academy of Sciences
(panzhao@mail.iggcas.ac.cn)
Huafeng Qin[3], Insititute of geology and geophysics, Chinese Academy of Sciences

Abstract

The reorientation of Earth through rotation of its solid shell relative to its spin axis is known as True polar wander (TPW). It is well-documented at present, but the occurrence of TPW in the geologic past remains controversial. This is especially so for Late Jurassic TPW, where the veracity and dynamics of a particularly large shift remain debated. Here, we report three palaeomagnetic poles at 153, 147, and 141 million years (Myr) ago from the North China craton that document an ~12° southward shift in palaeolatitude from 155–147 Myr ago (~1.5° Myr-1), immediately followed by an ~10° northward displacement between 147–141 Myr ago (~1.6° Myr-1). Our data support a large round-trip TPW oscillation in the past 200 Myr. By comparison of Jurassic paleomagnetic poles of the NCC and SIB, we suggest that the Late Jurassic true polar wander event may have biased paleomagnetic results and thereby affected the interpretation of the final closure of the Mongol-Okhotsk Ocean. Combining paleomagnetic data with regional geological evidence, we propose that the Mongol-Okhotsk Ocean was closed in its eastern segment in the Late Jurassic, marking the formation of the central Asian continent. We suggest that the shifting back-and-forth of the continents may contribute to the biota evolution in East Asia and the global Jurassic–Cretaceous extinction and endemism.

Cyclical and progressive destruction of the cratonic lithosphere of South China

Yang CHU[1]*, Institute of Geology and Geophysics, Chinese Academy of Sciences
(chuyang@mail.iggcas.ac.cn)
Wei Lin[2], Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

Continents with cratonic cores can resist deformation, and thus survive billions of years in the geological record. Tectono-thermal reworking is a key process in continental evolution because it alters composition and structure of some continents, weakens, and finally destructs or even dismembers them.

In western Pacific, East Asian continental margins suffered extensive continental reworking and lost part of their continental lithosphere and developed a wide extensional province. Across the South China Block, Mesozoic cyclical tectonics destructed a large portion of its cratonic lithosphere. We analyzed and synthesized the structural evolution of the extensional structures and illustrated the process of lithospheric thinning of Mesozoic South China.

Unlike the previous rapid, one-cycle delamination model occurred in the North China Craton, the destruction process of South China operates in a cyclical, progressive manner in which compression destabilized the edge of the cratonic lithosphere and the following extension destructs the unstable part to thin the lithosphere. This process, as an endmember of lithospheric destruction mechanisms, requires cyclical tectonics of the subduction zone and the overriding plate, which has been widely reported in the Cordilleras of the eastern Pacific margin. The progressive lithosphere destruction model may also explain how ancient cratons shrink by subduction-related tectonics.

Discussion on the Metallogenic Geological Body of the Qixiashan Pb-Zn Polymetallic Deposit in Jiangsu Province, China

Mingchao ZHANG[1]*, China University of Geosciences, Beijing (cgszhangmc@foxmail.com)

Abstract

Chinese mineral exploration expert Mr. Ye Tianzhu proposed the "Theory and Method of Prospecting and Prediction of Metallogenic Geological Body" since 2007. This theoretical framework systematizes large-scale mineral prediction techniques, focusing on Metallogenic geological body, Metallogenic structural planes and Metallogenic characteristics. In practical mineral exploration, this framework plays a pivotal role, contributing significantly to China's mineral exploration endeavors in the past two decades and yielding commendable results.

The Qixiashan Pb-Zn polymetallic deposit, situated within the Nanjing-Zhenjiang area of Jiangsu Province. Through the analysis of metallogenic geological characteristics, fluid inclusions, and isotopic compositions, the mineralization of the Qixiashan deposit is a magmatic hydrothermal deposit primarily influenced by the Calcium-Silicon Interface between Carboniferous limestone of the Huanglong Formation and sandstone of the Gaolishan Formation, the absence of an identified intrusive rock body linked to mineralization within the mining area has sparked controversy regarding the determination of the Metallogenic geological body. Metallogenic Geological Body pertains to geological bodies intricately linked to mineral deposit formation concerning time, space, and genesis. The physical carrier of Metallogenic geological processes is the Metallogenic geological body, specifically referring to the structural characteristics and rock combination types. Identifying Metallogenic geological bodies facilitates precise prediction of deep mineral deposit locations, thus providing crucial insights for further exploration efforts.

Through comparative studies encompassing geological phenomena, geochronology, isotopic geochemistry of this mining area, and rare earth element geochemistry of relevant intrusive rock bodies, we infer the Metallogenic geological body of the Qixiashan deposit to be a moderately acidic concealed intrusive rock body formed by magmatic activity within the Tangshan-Zhenjiang rock foundation. Our assertions are supported by the following observations: 1) To date, Although no intrusive rock formations are directly observable within the mining area, scattered occurrences of diorite porphyrite veins have been identified on the surface of Ganjiaxiang and within boreholes.Such vein formations typically develop in the vicinity of intrusive rock bodies and serve as significant indicators for the potential existence of concealed intrusive formations. And alongside the presence of Yanshanian granodiorite and pyroxene diorite in neighboring regions. 2) The genesis of the Qixiashan deposit ore and the emplacement of the principal acidic intrusive rock body within this locale are governed by nearly east-west (northeast) trending faults of this area, suggesting a spatial correlation between the two phenomena. This alignment hints at a potential synchronicity in their formation epochs and tectonic dynamic processes. 3) The Qixiashan mining area exhibits subtle gravitational and magnetic anomalies characterized by a gentle and low magnitude. Studies propose that the underlying magnetic source responsible for

these anomalies likely corresponds to a concealed intrusive rock body situated at the core of the Da-Ao Mountain anticline. This hidden intrusive body is estimated to be shallowly buried, with depths ranging approximately 1300 meters and extending over a width of around 2300 meters.
In mineral exploration and prediction endeavors, the identification of metallogenic geological body is paramount for determining deep mineral exploration spaces. We suggest that future exploration efforts at the Qixiashan deposit should prioritize the search for hidden metallogenic geological.

Mesozoic Uplift of the Dabashan and the Micangshan-Hannan Dome in the South Qinling Orogenic Belt determined by analysis of lithospheric flexure

Xiong XIONG[1]*, China University of Geosciences (xxiong@cug.edu.cn)
Yongdong Li[2], China University of Geosciences

Abstract

The knowledge of the evolution of topography in continental orogeny is vital for understanding continental orogenic processes, geodynamic mechanisms, and climate and environmental changes. The Qinling orogen is a major orogenic belt in mainland China, and its uplift history is key to the tectonic configuration and geodynamics of China and East Asia. Previous studies have shown that the Dabashan and the Micangshan-Hannan Dome in the South Qinling orogen were uplifted during the Mesozoic, however, the amplitude of the uplift remains unresolved. In this study, based on the sedimentary records of the northern Sichuan Basin and using lithospheric flexural modeling, we have estimated the scale of Mesozoic uplift of the Dabashan and the Micangshan-Hannan Dome, and the effective elastic thickness (Te) of the Sichuan Basin. The results show that the Dabashan and the Micangshan-Hannan Dome were uplifted approximately 1220 and 880 m during the Middle Jurassic and Early Cretaceous, respectively. On this basis, we propose that the present-day elevation of the Dabashan and the Micangshan-Hannan Dome is primarily the result of Mesozoic uplift. The differences in uplift duration and amplitude of different tectonic units indicate that the uplift processes and driving mechanisms of the South Qinling orogen were different in the Mesozoic and Cenozoic. While Mesozoic uplift was a result of the convergence of the North China and the South China Blocks from east to west, Cenozoic uplift was driven by ongoing indentation of the Indian plate into Eurasia from southwest to northeast. The lithospheric strength of the northern Sichuan Basin weakened from the Middle Jurassic to the Early Cretaceous, and Te decreased from 73 to 57 km, which may have been caused by the bending stresses developed in the lithosphere beneath large topographic loads due to flexure.

Young-Seog Kim[6], PUKYONG NATIONAL UNIVERSITY

Abstract

Deformed soft-sediment deformation structures (SSDS) may reveal multiple phases of deformation, offering crucial clues about the inversion mechanisms in a basin. In this study, we detail the deformation inversion history from the Miocene to the Holocene (phases 1–4) within the Bomun sub-basin, located in the Gyeongju area of southeastern Korea. The consistent direction of the WNW-trending folds that plunge westward across different sites suggests they were formed by tectonic forces. Our analysis of paleostress in reverse faults that have shifted Miocene deposits and SSDS identified an ENE compression direction (σ_Hmax) that aligns with the current stress orientation. The presence of distinct liquefaction features, their widespread distribution, and the repeated vertical occurrence of SSDS point to significant seismic influence. The brittle deformation seen in outcrop and microscopic analyses near reverse faults, including the formation of clastic dikes within SSDS, suggests seismic triggers. Evaluating the Environmental Seismic Intensity (ESI-07) scale with SSDS data indicates that the area around the Bomun sub-basin likely experienced seismic events ranging in intensity from IX to X, which contributed to the noted deformation characteristics. The investigation into SSDS not only sheds light on the area's dynamic processes but also aids in advancing research on seismic risks and the mechanisms of basin inversion.

This research was supported by a grant(2022-MOIS62-001(RS-2022-ND640011)) of National Disaster Risk Analysis and Management Technology in Earthquake funded by Ministry of Interior and Safety(MOIS, Korea).

Intraplate neotectonics and activity of thrust segment in the Ulsan fault, SE Korea

Kiwoong PARK[1]*, Pukyong National University (pko8108@naver.com)
Sambit Prasanajit Naik[2], Pukyong National University
Young-Seog Kim[3], Pukyong National University

Abstract

Challenging the traditional perception of seismic stability in the Korean Peninsula despite its distance from major plate boundaries, recent moderate earthquakes near the Yangsan and Ulsan faults in the southeastern region, notably the 2016 Mw 5.5 Gyeongju earthquake and the 2017 Mw 5.4 Pohang earthquake, have underscored the imperative of comprehending regional seismic activity, thus prompting heightened interest in paleoseismological research focusing on these fault systems. The Ulsan fault zone, which extends approximately 60 km from Ulsan to Gyeongju city, represents a significant reverse-dominant fault system trending NNW-SSE in the region. Direct evidence of Quaternary reactivation along the Ulsan fault zone remains scarce despite inference from geological mapping, geomorphological features linked to the eastern mountain range uplift, and geophysical surveys, primarily due to extensive sediment cover in urbanized zones. Additionally, the presence of numerous continuous active faults along the mountain front area, situated approximately 4 to 5 km east of the Ulsan fault, not only manifestation ongoing activity in the region but also emphasizes the importance of comprehending the intricate nature of fault development. Therefore, this study aims to comprehensively investigate the Ulsan fault zone by examining both geomorphological thrust segmentation and paleoseismic parameters, such as slip rate and recurrence interval. Furthermore, we propose a systematic method of examining deformation activity of thrust segment in Ulsan fault, integrating kinematic fault behavior, structural characteristics, and geomorphological features of the mountain front. This comprehensive approach seeks to provide a detailed understanding of fault characteristics within the intraplate region.

Long-term patterns of paleo-earthquakes influenced by climate change on the Korean Peninsula

Man-Jae KIM[1]*, Pusan National University (amond0314@pusan.ac.kr)
Moon Son[2], Pusan National University
Hee-Kwon Lee[3], Kangwon National University

Abstract

The periodicity of earthquakes, whether time-dependent or time-independent, has been a focal point in fault research across various tectonic settings. Moreover, recent studies highlight an intriguing connection between climate change and its influence on tectonic activity. In this study, paleo-earthquake records were established by utilizing electron spin resonance (ESR) age data to conduct a statistical analysis of Quaternary fault activity patterns in four fault zones (Keumwang, Wangsukcheon, Yangsan, and Ulsan) on the Korean Peninsula. The primary objective of this analysis is to distinguish between competing models of earthquake periodicity. By employing 454 ESR data, we identified four active paleo-seismic phases for the Keumwang fault zone, four for the Wangsukcheon fault zone, eight for the Yangsan fault zone, and seven for the Ulsan fault zone. The calculated COVs and p-values indicate that the distribution of active paleo-seismic phases within each fault zone shows a quasiperiodic pattern over an extended timeline. Both the Keumwang fault zone (COV: 0.129 ± 0.076; p-value: 0.018) and the Wangsukcheon fault zone (COV: 0.143 ± 0.120; p-value: 0.028) demonstrate quasiperiodic patterns of active paleo-seismic phases. Similarly, the Yangsan fault zone (COV: 0.258 ± 0.106; p-value: 0.005) and the Ulsan fault zone (COV: 0.270 ± 0.121; p-value: 0.012) exhibit quasiperiodic patterns of active paleo-seismic phases. These observed patterns align with a time-dependent earthquake recurrence model, suggesting a regional baseline for fault activity with a periodicity of approximately 100 kyr.

We further correlated the distribution of active paleo-seismic phases from four distinct fault zones with the δ18O record from the LR04 marine benthic stack. This record serves as a reliable proxy for marine isotope stages (MIS), offering insights into the frequency of fault activities within the context of climatic variations. Over the past 650 kyr, the periodicity of active paleo-seismic phases has aligned with the interglacial periods of MIS 15, 13, 11, 9, and 7. On the Korean Peninsula, we hypothesize that long-term differential stress changes, resulting from sea-level rises in the Pacific Ocean, have played a significant role in driving Quaternary fault activities during these interglacial stages. As a result, this study proposes that the ongoing global warming might lead to a potential increase in earthquake frequency on the Korean Peninsula.

Abstract

The Western Anatolian Extensional Province features E–W trending graben systems formed under Aegean N–S extension. Tectonics along the Aegean coast of Western Anatolia involve a mix of extension and strike-slip faulting, leading to frequent earthquakes due to seismically active normal faults. The 30 October 2020, Mw 7.0 Samos earthquake ruptured an east–west normal fault located offshore the northern coast of Samos Island, Greece, near the Gulf of Kusadası, Western Turkey. Analysis of the main shock and aftershocks revealed an east-west trending, north-dipping normal fault, with aftershocks exhibiting strike-slip and normal faulting component. However, the unknown continuation of onshore faults from Kuşadası to the Gulf of Kusadası complicates interpretation of the interaction between the ruptured Samos fault and neighboring active faults. To address this, TÜBİTAK organized extensive offshore surveys in 2021 and 2022 to characterize submarine faults in the Gulf of Kusadasi and assess the future earthquake risk of the region. R/V TÜBİTAK Marmara conducted two surveys, collecting bathymetry, CHIRP, and Sparker data to map offshore faults, and recover sediment gravity cores to evaluate submarine paleoseismology. Multi-beam bathymetry and seismic reflection data from the Gulf of Kuşadası show morphologic and sub-bottom traces of numerous normal faults within a deformation zone widening westward. Most of these faults cut the basin fill and the sea bottom with vertical throws ranging from ~7-18 m. Faults mapped within the Gulf of Kuşadası exhibit typical graben and horst structures consistent with the regional extensional tectonics. North of the Gulf, several N-S striking strike-slip faults i.e. Seferihisar and Tuzla Faults extend offshore. However, based on seismic reflection data, these faults appear to dissipate towards the south. Several normal faults are mapped between Samos Island and the southern part of Kuşadası. Interestingly, some of these faults seems to be the extension of unmapped onland faults in Western Turkey.

The Late Pleistocene-Holocene sediment stratigraphy within the Gulf of Kuşadası was analyzed by CHIRP data and multi-parameter analysis of sediment gravity cores. CHIRP data show

evidence of syn-tectonic sedimentation during the Last Glacial Maximum and the later post-glacial transgressive periods that are marked by the prominent reflection surfaces. Correlation of the sediment cores with high-resolution seismic data allow us to calculate vertical throw rates ranging between ~0,5 mm/yr to ~2.2 mm/yr. Multi-parameter analysis based on geochemical and physical proxies of the gravity cores reveal evidence of earthquake triggered mass flow deposits (seismo-turbidites). The gravity cores also yield sedimentary evidence of the 2020 Mw 7.0 Samos earthquake, along with records of past seismic events dating back to 2500 yrs BP, 3700 yrs BP, 4300 yrs BP.

There is ongoing aftershock activity along the Samos Earthquake rupture zone and neighboring extensional faults controlling the Gulf of Kuşadası, which overlaps with 20 years of persistent earthquake activity. Following the 2020 earthquake, triggering events (Mw>4) were observed both in the Ikeria basin and in the eastern part of the Gulf of Kuşadası. This activity pattern, together with the dataset obtained during the surveys, suggest potential seismic risk for future earthquakes within this region.

Abstract

Volcanic hazard assessment has been extensively studied all over the world by considering active volcanoes, but little concern was given to the dormant volcanoes. However, these dormant volcanoes can be reactivated by stress changes as well as fluid pressure in the substrate. Therefore, the analysis of fracture patterns and stress conditions is crucial for determining the possibility of the occurrence of volcanic eruption in the area. The study of volcanic morphology has revealed its importance in understanding subsurface fractures, substrate stress, and volcano-tectonic processes within the area. The change in substrate stress greatly controls the opening of fractures and thus affects the activity of volcanoes and earthquakes in the region. This study focuses on discerning the volcanic activity dependencies on the orientation of stress within the Kivu Rift, the western branch of the East African Rift. Several parameters, such as ellipticity, crater diameter, breaching azimuth, and volcanic cone alignment, were measured on 150 volcanoes within the Virunga Volcanic Complex. An intriguing pattern emerges, highlighting that volcanoes, such as Nyiragongo and Nyamuragira aligned along the N-S-striking faults, exhibit active behavior, correlating with the prevalent regional extensional stress directed in the E-W orientation. In contrast, most of the volcanoes following E-W, NE, and NW trends portray dormant characteristics, possibly related to the rotation of the extensional stress in the area. This study underscores the critical interplay between structural factors and volcanic activity, suggesting a potential predictive model for volcanic hazards based on stress orientation. Furthermore, it could offer significant implications to their potential reactivation with stress change for volcanic hazard assessment and proactive risk management strategies in the Kivu Rift region especially in countries such as Rwanda, the Democratic Republic of Congo, and Uganda.

Abstract

At Shallow crustal depths, crystals compensate for strain through brittle deformation; however, as depth increases, the grain scale deformation mechanism turns into ductile through the migration of lattice defects. Even though these dislocations may not be observed under an optical microscope, other microscopic features like twinning, kinking etc. may indicate their effects in a crystal lattice. In addition to the primary constituent minerals such as quartz, and feldspar, the secondarily formed clay minerals may also accommodate strain in such a manner which can have control over the recurrence and magnitude of the earthquakes. The subsurface faults (0.9 to 3 km depth) in the granitoid basement rocks of the Koyna-Warna intraplate Seismogenic Region in Western India are highly stressed due to the combined action of the plate tectonic forces transmitted from the boundaries and impoundment of the reservoirs. The major elemental geochemistry on the core samples collected from 0.9 to 3 km depths, as a part of the Continental Scientific Drilling Program, suggests that fluid percolated through the permeable faults and interconnected fractures has caused the fluid interaction with primary constituent minerals like biotite and plagioclase and resulted in the formation of several secondary minerals with a predominance of chlorite which the XRD studies have also reaffirmed. In addition, the in-depth petrologic investigation has revealed kinking in the neoformed chlorites which demonstrates the intracrystalline ductile deformation in response to immense stress. Actually, the talc-like T-O-T sheets and brucite-like octahedral sheets that make up the chlorite crystal are bonded together by weak hydrogen bonds. Stress buildup in the fault zones causes the shortening of the hydrogen bonds which makes it stronger. Hence, in order to accommodate strain, the chlorite crystal forms a number of atomic scale ripples on its basal plane. Later, the bonds become weaker owing to the bond angle reduction when the imposed stress reaches a threshold. However, the bonds are not broken, as the small-scale ripples formed earlier begin to migrate with the energy gained and merge into kink bands. Thus, the yield strength of chlorite increases with an increase in stress keeping the hydrogen bonds intact which makes its crystal capable of withstanding most of the stress, through visco-elastic intracrystalline

deformation. This type of ripplocations mechanism brought on by chlorite is far more favourable for fault creep, which could be a cause of recurrence of small magnitude earthquakes rather than a large and destructive one, as also seen over the past 50 years in the Koyna-Warna Seismogenic region.

Earthquake Geology of the Mogod Fault, Mongolia

Hankyung Bae[1], Korea Institute of Geoscience and Mineral Resources
Jin-Hyuck CHOI[2]*, Korea Institute of Geoscience and Mineral Resources (cjh9521@kigam.re.kr)
Dong-Eun Kim[3], Korea Institute of Geoscience and Mineral Resources

Abstract

The 1967 Mw 7.0 Mogod earthquake is the largest earthquake in the central Mongolia, one of the slow-deforming yet active regions. The earthquake rupture occurred on the complex fault system composed on the strike-slip and reverse-slip dominant inherited geologic structures. Here, together with rupture mapping using high-resolution satellite/drone images, we conduct geological surveys and geophysical explorations to understand the segment geometry of the fault system and its roles on rupture behaviors. As results, the ~47-km-long ruptures used five fault geometric segments; four strike-slip segments and one reverse-slip segments, as the pathway of the rupture propagation. We estimate an average horizontal slip of 1.9 ± 1.4 m and a vertical component of ~0.7 m from the 1967 event, and cumulative offsets larger than a few meters suggesting multiple seismic events. We test the rupture history for each fault segment by paleoseismological excavations. The results imply that strike-slip segments have ruptured more with a shorter recurrence time rather than the reverse-slip segments. This suggests that the 1967 earthquake was unusually large in scale. Also, we estimate the long-term slip-rate based on 3D trench survey and a grand cumulative offset aged by cosmogenic dating. Along-fault complexity of rupture geometry, variations in offset and rupture history imply that rupture behaviors and recurrence are strongly controlled by inherited fault structure.

Paleoseismic event timing and surface rupture scenarios on the Yangsan Fault, SE Korea

Taehyung KIM[1]*, Korea Institute of Geoscience and Mineral Resources (adrian0305@kigam.re.kr)
Jin-Hyuck CHOI[2], Korea Institute of Geoscience and Mineral Resources

Abstract

Understanding the spatiotemporal behavior of faults from a seismic hazard assessment perspective is crucial. However, deriving paleoseismic information in regions with slow deformation, such as intraplate areas, is challenging. This study synthesizes the results of multiple trench surveys conducted on a section of the Yangsan Fault (YF) within the intraplate environment, presenting paleoseismic surface rupture scenarios. These are discussed in conjunction with previous studies. The YF, having undergone multiple deformations since the Cretaceous, has developed over 200 km as a long-lived fault. In the current tectonic stress environment, it is an active dextral strike-slip fault. This fault merges with the large reverse Ulsan Fault (UF) in a NW-SE direction near Gyeongju City, delineating the northern Yangsan Fault (NYF) and Southern Yangsan Fault (SYF). Paleoseismic trench surveys conducted over approximately 10 km of the SYF suggest that the most recent earthquake (MRE) occurred between 28-16 ka. Penultimate seismic events took place between 39-35 ka, with earlier ones occurring between 74-49 ka. The trench-derived paleoseismic records indicate two possible scenarios: (1) a complete rupture across the entire studied segment during each seismic event, or (2) multiple partial ruptures affecting the two structurally distinct parts of the studied fault segment, namely the Wolsan–Miho and Inbo north–Inbo sections. While the NYF and UF indicate MRE in the Holocene, the SYF may not have experienced a paleoearthquake during this period. However, this suggests the possibility of undiscovered paleoseismic records at these locations, necessitating further investigation.

The silent and slow active faults of Germany: results from paleoseismological trenching

Klaus REICHERTER[1]*, RWTH Aachen University, Inst. of Neotectonics and Natural Hazards (k.reicherter@nug.rwth-aachen.de)

Abstract

The phenomenon of silent and slow faults presents a particularly intriguing challenge in the study of active tectonics, especially in regions classified as Stable Continental Regions (SCR) or Active Intraplate Regions (AIR), such as Central Europe. The term "silent faults" encompasses various meanings, either indicating a lack of seismic activity, absence of faulting that generates earthquakes (though possibly exhibiting creep), or referring to faults with minimal geomorphic and geological visibility.

Slow active faults typically exhibit slip rates of ≤ 0.1 mm/yr, often lacking significant topographic features in regions with humid to moderate climates. The slip rate of a fault is a critical parameter governing earthquake occurrence and seismic hazard, with decreasing slip rates extending the average recurrence intervals of earthquakes of a particular magnitude. Consequently, earthquakes on low slip-rate faults are frequently absent from historical records and standard seismic hazard assessments due to their lengthy recurrence intervals.

New fault data from several AIR, specifically the Rhine Graben rifts, and SCR regions in Germany, particularly the Lower and Upper Rhine Grabens, are presented based on seismological, geophysical, and trenching investigations. Holocene surface rupturing events are uncommon, with recurrence intervals typically spanning 1,000-10,000 years, and associated slip rates remaining below 0.5 mm/yr, or even ≤ 0.1 mm/yr. While secondary earthquake effects are observed more widely, some faults exhibit distinct linear scarps and topographic features, as evidenced by highresolution Digital Elevation Models (DEMs) and field surveys.

The preservation of minor scarps in agricultural areas poses an enigma, with scarps as low as approximately 50 cm from a single event being preserved for 1,000-10,000 years. However, recurring paleo-earthquakes are documented in surface deposits, as demonstrated by trenching in the Upper Rhine Graben. Geodetic techniques such as GPS and Differential Synthetic Aperture Radar Interferometry (DInSAR) offer means for detecting silent faults, although signals may be influenced by factors such as groundwater extraction and vegetation. Moreover, some normal faults in the Lower Rhine Graben exhibit evidence of "Clustering and Quiescence" earthquake occurrence, potentially explaining the persistence of scarps over time and contrasting the "One Shot" hypothesis sometimes proposed for SCR faults.

The integration of high-resolution geodetic techniques with classical paleoseismological

investigations offers a promising approach for uncovering the history of silent and slow faults. Despite challenges posed by environmental factors, these methods hold potential for enhancing our understanding of fault activity in such regions.

The Evaluation and Morphometric analysis of Active Tectonics in Zagros Folded Belt (ZSFB), West of Iran

Reza Mansouri[1], Department of Physical Geography, Faculty of Geography and Environmental Planning, University of Sistan and Baluchestan, Zahedan, 98167-45845, Iran
SAMBIT PRASANAJIT NAIK[2]*, PUKYONG NATIONAL UNIVERSITY (sambitnaik@gmail.com)
Swakangkha Ghosh[3], NIIT University, NH-8, Neemrana, Rajasthan, India

Abstract

Geomorphic indices are useful tools in the evaluation of active tectonics because they can provide rapid insight concerning specific areas within a region that is undergoing adjustment to relatively rapid, and even slow, rates of active tectonics. Thus, Tectonic geomorphology, due to its rapid, low-cost, and easy-to-perform techniques, can be an excellent tool to improve the understanding of the development of fold belts such as the Zagros that contain some 49% of the global fold and thrust belt-related hydrocarbons. Zagros orogenic belt is one of the best examples of active orogeny in the world, arising from deformation caused by Neogene continental collision between the Arabian and Eurasian plates. The study area is geographically located in the west of Iran and geologically in the northwestern part of the Zagros Simply Folded Belt (ZSFB). The aim of this study is the assessment of active tectonics and neotectonics movements in three selected anticlines in west of Iran (north of Ilam province) using Geomorphic indices, GIS, RS, and fieldworks. Morphometric analysis in this study involve 8 geomorphic indices such as: Mountain front facet (FMF), Mountain front sinuosity (SMF), Aspect Ratio (AR), Ratio of Valley Floor Width to Valley Height (VF), Fold Front Sinuosity (FFS), Fold Symmetry Index (FSI), Percentage undissected escarpments (EU), Percentage dissected mountain fronts (FD). These Morphometric indices were integrated together to obtain the Relative Tectonic Activity Index (Iat) using the GIS and RS approach. These three anticlines are: Bayeh, Bankoul and Keteh Pifak anticlines, that are stretched parallel with the main direction of the Zagros folded belt from northwest-southeast. The pressure direction of the Arabian plate in the study area is N30-40E. In terms of structural geomorphology, the general landscape of the study area has anticline-syncline structures. The morphometric features of these anticlines were determined using topographical and geological maps, Landsat 9 and Sentinel 2 satellite imageries, Google Earth, DEM 12.5 m, GIS and RS and several fieldworks. The findings obtained for the investigated indices in these anticlines showed that the structure of them is young and the neotectonics movements are still continuing; Therefore, they are in an active state in terms of tectonics. The high values of the FMF, EU, AR indices and the low values of the FD, VF, FFS, FSI, SMF indices show the young and asymmetry of the anticlines, the continuation of the effect of neotectonics movements and uplifting, and less erosion in them. In addition to the calculated quantitative values for these indices, the geomorphological evidences in the study area including straight and faulted mountain fronts, faulted escarpments, V-shaped valleys, asymmetric fold, larger triangular facets with longer base length, shorter and steeper limb, more Percentage Undissected Escarpments and lesser Percentage Dissected

Mountain Fronts in the southwest limb, indicates the more active tectonic condition in this section compared to the northeast limb of the anticlines. The output of this study shows the importance of using several datasets with different origins and their overlay in a GIS platform for evaluating the neotectonics activities in these anticlines or elsewhere.

Numerical modelling of tectonic stress and deformation of the Andaman Subduction Zone

Radheshyam YADAV[1]*, CSIR-National Geophysical Research Institute, Hyderabad (shamgpbhu@gmail.com)
Virendra M Tiwari[2], CSIR – National Geophysical Research Institute, Hyderabad, India

Abstract

The Sumatra-Andaman subducting zone evolved from the Indo-Australian plate's oblique subduction beneath the Eurasian overriding plate. Due to oblique subduction, variations of age and convergence velocities of Indo-Australian make the Andaman subduction zone complex and active seismic region. Therefore, a three-dimensional (3D) numerical simulation model of the Andaman subduction region (88 to 980E & 5 to 140N) was developed to investigate the tectonic process and model parameters which were mainly responsible for the observed surface deformation and stress in the interaction boundary of the subducting and overriding plate. The geometry of the numerical simulation model was derived from the 3D density model that was derived from the joint modelling of satellite free air anomalies and geoid undulation with accessible other geophysical and geological constraints. The boundary condition is taken from the plate velocity of the subducting plate and material properties from the seismic velocities and density. The results (stress, strain and velocities) are calculated for different rheologies (elastic and viscous). The calculated velocities of the numerical simulation model show a good correlation with the observed Global Positioning System (GPS) velocity component (East-West and North-South). The stress of this FEM is fit with the hypocenter of the earthquakes at the interaction of the subducting and overriding.

The Eastern English Channel (North of France) : Some examples of intraplate tectonics and seismicity

Virginie GAULLIER[1]*, LOG - Université de Lille - France (virginie.gaullier@univ-lille.fr)
Olivier AVERBUCH[2], LOG - Université de Lille
Aboubacar DIBOUSSE[3], LOG - Université de Lille
François Guillaume SCHMITT[4], LOG - Université de Lille

Abstract

The Eastern English Channel, between SE of England and the French coast, is a complex domain, resulting from the major tectonic deformations that affected the West European margin at the Late Jurassic-Early Cretaceous (extension and subsidence due to the propagation of the opening of the North Atlantic Ocean) and during the Cenozoic (compression causing the inversion of basins linked to the African-Eurasian convergence). Both extensional and compressional deformations involve the reactivation of older major regional structures, inherited from the Variscan Orogeny. However, the detailed structural development of this domain still remains poorly constrained, as well as the detailed stratigraphic framework of Cenozoic series, notably in terms of sequence stratigraphy. Since 2014, an intensive exploration has been carried out to acquire approximatively 4500 km of very high-resolution seismic data (Sparker) during several oceanographic cruises (TREMOR 1, 2014; TREMOR 2, 2017, GEOBAS 2016-2023; MARCOPALE, 2023), onboard the R/V “Côtes de la Manche”, “ANTEA” and “SEPIA II”. The interpretation of these new data allowed to precisely map many tectonic features, as faults, folds and monoclinal flexures, especially in the Dieppe-Hampshire Basin. We especially imaged the complexity of the deformation within the highest tectonized zones of the region, along the North-Bay of Seine Basin and offshore the Boulonnais coast with an unprecedented resolution. This deformation pattern illustrates two major structural trends, respectively E-W and NW-SE directed, both syn- to post-Bartonian in age. The first one is consistent in age and orientation with a late Pyrenean or early Alpine de-formation phase, while the second one appears to have a different origin, in regards to the overall geodynamic framework. We suggest that the major heterogeneities of crustal blocks underlying the basin played an important role on the development and orientations of these deformations. In the framework of these offshore works, we undertaken onshore study, along the Boulonnais coast, especially in front of the Dover Strait. Gris-Nez Cape is one of the most striking features of the fault system bordering the inverted Weald-Boulonnais basin. The Sirène beach, which has been heavily cleared of sand over the past 20 years, reveals the complexity of the folded and faulted geological structures. Over the last few years, detailed structural surveys have been carried out onshore, using GNSS layer-to-layer mapping. This mapping has been recently completed by photogrammetric surveys by drone at very high spatial resolution (5 cm) allowing to obtain an ortho-mosaic and a digital terrain model of the foreshore and cliffs of Cape Gris Nez. The interpretation of these very high-resolution images leads to a better understanding of the geometry and kinematics of the deformations of this complex area. Since the Eastern English

Channel is affected by a moderate but regular seismicity (up to 5-6 in magnitude) et considering the presence of numerous human infrastructures such as Seveso sites, nuclear power plants and the Channel Tunnel, we aim to characterize the fault pattern in order to better define the alea and therefore the seismic risk.

A study on petrofabrics of garnet in calc-silicate rocks in the Yeongnam Massif, South Korea

Seokyoung HAN[1]*, School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea (hs04111@snu.ac.kr)
Ji-Hoon KANG[2], Department of Earth and Environmental Sciences, Andong National University, Andong, Republic of Korea
Haemyeong JUNG[3], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea

Abstract

Garnet, a prevalent mineral in metamorphic rocks, is found across various lithologies within the continental basement, subducted crustal slab, and upper mantle. Quartz is also an important constituent mineral which occurs widely in most rock types in both upper and middle crust. Understanding the deformation mechanism of quartz and garnet in nature is essential, as they potentially influence rheological properties of rocks forming major tectonic structures. The Cheongsong area in South Korea is the region where Precambrian gneiss and Paleozoic calc-silicate rock, gneiss, and amphibolite are exposed. These metamorphic complexes are situated close to the granite suites associated with the Permo-Triassic tectonic event, and structures formed in several stages of ductile and brittle deformations, and intrusion of felsic dykes are preserved in outcrops. It is expected that petrofabric analysis of deformed garnet, along with highly deformed and recrystallized quartz, can contribute to understanding the deformation conditions of garnet and quartz. For this purpose, samples of calc-silicate rocks and metasedimentary rocks in the Cheongsong area were collected and the lattice-preferred orientations (LPOs) of constituent minerals were analyzed using the electron backscattered diffraction (EBSD) technique. The analyzed samples consist mainly of quartz and feldspar, with minerals formed by contact metamorphism such as garnet, wollastonite, and diopside, as well as minor titanite, apatite, prehnite, and pumpellyite. Our EBSD data of samples for the c-axis distribution of totally recrystallized quartz showed an activation of prism<c> slip system of quartz, indicating the deformation of quartz at high temperature. In the EBSD maps (grain reference orientation deviation) of these samples, garnet showed deformation microstructures indicating plastic deformation by dislocation creep. Based on plastic deformation of garnet and large c-axis opening angle of quartz LPO, it is inferred that the deformation temperature of the calc-silicate rock was relatively high (above 600 ℃). Additionally, four-grain junctions in the other area of sample were observed in the clusters of small garnet grains, indicating grain boundary sliding of garnet.

Preliminary results of the deformation texture of diopside in serpentinite

Jungjin LEE[1]*, Seoul National University, Seoul, Republic of Korea (ljj2718@snu.ac.kr)
Haemyeong Jung[2], Seoul National University, Seoul, Republic of Korea

Abstract

Seismic anisotropy has been ubiquitously observed in worldwide subduction zones, and the strong crystallographic preferred orientation (CPO) of composite minerals in subduction-related rocks, especially serpentinites in hydrated forearc mantle, has been regarded to strongly influence the seismic anisotropy in subduction zones. Diopside is an important pyroxene group mineral present in serpentinites. However, the CPO of diopside and its deformation mechanism in serpentinites are poorly understood. In this study, a new CPO type of diopside was observed in diopside aggregates in the foliated serpentinites from Monte San Petrone in Alpine Corsica (France). CPOs of diopside and antigorite were analyzed using the SEM-EBSD technique. The diopside CPOs showed a strong alignment of the (100) poles subnormal to the foliation and a girdle distribution of [010] and [001] axes subparallel to the foliation, which have been rarely reported in previous studies. The antigorite CPOs showed strong maxima of the (001) poles subnormal to the foliation and a girdle of [100] and [010] axes subparallel to the foliation. Seismic anisotropies induced by the new CPO type of diopside were also calculated. The results indicate that the new CPO of diopside influences trench-normal seismic anisotropy of S-wave, lower Vp/Vs ratios, and negative radial anisotropy in anhydrous portion of subducting lithosphere. Future research is needed to understand the effect of the diopside CPO on the formation of the CPOs of other major minerals in subduction zones.

Seismic anisotropy of slaty rocks: Unveiling the effect of the CPO on seismic properties

Victor CARDENES[1]*, Department of Geology, University of Oviedo (cardenesvictor@uniovi.es)
Marco A. López-Sanchez[2], University of Oviedo
Sergio LLana-Fúnez[3], University of Oviedo

Abstract

Slaty rocks form a group belonging to the greenschist facies which have in common a deep and penetrative structure formed by the alignment of mica minerals, the slaty cleavage. There are four rocks displaying different degrees of this structure: metapelites, slates, phyllites and mica-schists. These rocks are also a major component of the continental crust and sedimentary basins, playing a crucial role in seismic-wave propagation and fluid flow within the middle and upper continental crust. Their pronounced seismic anisotropy and low permeability make them particularly significant. Despite their volumetric significance, most seismic property studies on phyllosilicate-rich rocks have been predominantly focused on shales, a sedimentary rock displaying an incipient slaty cleavage, driven by their economic relevance in the petroleum industry. This has led to a notable imbalance in the research conducted on the seismic properties of shales compared to slaty rocks, and it remains unclear whether the seismic properties of shale can be directly extrapolated to metamorphic rocks. We aim to address this gap by establishing the average and variance of seismic properties of slaty rocks with different degrees of metamorphism. We have used state-of-the-art Voigt-Reuss-Hill (VRH) averaging schemes based on wide-coverage Electron Backscatter Diffraction (EBSD) maps. Our data allows us to discuss the validity of different models of polar seismic anisotropy in slaty rocks and identify cases where these models break down. We also explore whether mica content and Crystallographic Preferred Orientation (CPO) intensity are reliable predictors of seismic properties

Deformation microstructures and seismic anisotropy of Yeoncheon amphibolites in the Imjingang Belt, South Korea

Sejin JUNG[1]*, School of Earth and Environmental Sciences, Seoul National University, Seoul (shazabi7@snu.ac.kr)
Junha Kim[2], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea
Haemyeong Jung[3], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea

Abstract

The Imjingang Belt preserved the deformation and metamorphism of rocks related to the Permo-Triassic continental collision between the North and South China Cratons. To understand the microstructural evolution of amphibolites, microstructures of amphiboles in Yeoncheon amphibolites and psammitic schists were analyzed using electron back-scattered diffraction mapping and transmission electron microscopy. Two different types of lattice preferred orientations (LPOs) of amphibole were observed: type-II and type-IV. The subgrain boundaries of amphibole, misorientation axes distribution of amphibole, and existence of relict clinopyroxenes inside the amphibole indicate that the type-IV LPO of amphibole resulted from deformation by dislocation creep and topotactic growth of amphibole. Type-IV LPOs of amphibole can be interpreted as a fabric developed at the peak metamorphic condition. The low-angle boundaries of amphibole associated with cracks and fractures in some samples indicate that type-II LPO of amphibole resulted from cataclastic flow associated with rigid body rotation during retrogression. The seismic velocity and anisotropy of the Yeoncheon amphibolites showed that the seismic anisotropy of the amphibolites followed that of the amphibole. Seismic anisotropy of the amphibolites with the type-IV LPO of amphibole was significantly weaker than that of the amphibolites with the type-II LPO, suggesting that the fabric transition from type-IV to type-II LPO of amphibole may significantly strengthen the seismic anisotropy of the amphibolite.

Chlorite dehydration in chlorite peridotite and implications for intermediate-depth earthquakes in subducting slabs

Haemyeong JUNG[1]*, Seoul National University (hjung@snu.ac.kr)
Dohyun KIM[2], Seoul National University
jungjin LEE[3], Seoul National University

Abstract

Intermediate-depth earthquakes are common in the double seismic structures of many subduction zones under high pressures (~1–4 GPa). Serpentine dehydration exhibits well-established links with double seismic zone earthquakes. Additionally, dehydration of several hydrous minerals including lawsonite and chlorite underlying the upper and lower layers, respectively, may be responsible for intermediate-depth earthquakes. Chlorite exhibits a wide stability range in subduction zones under high P-T conditions. Chlorite peridotite is stable in the lower layer of double seismic zones. Based on previous laboratory experiments and seismicity correlation studies, researchers have inferred that seismicity in the lower plane of double seismic zones could be linked to the dehydration of hydrous minerals, including serpentine and chlorite. Here, we present experimental evidence suggesting that chlorite dehydration can trigger intermediate-depth earthquakes at the lower plane (~700 °C). We conducted deformation experiments on chlorite peridotite under high-pressure (0.5–2.5 GPa) and high-temperature (500–750 °C) using a modified Griggs apparatus. Experiments revealed the presence of faults in samples that had undergone partial chlorite dehydration with the presence of the dehydration product Ca-amphibole along these faults. Our findings confirm, together with correlation studies between seismicity and mineral stability, that a part of intermediate-depth seismicity in the lower plane of double seismic zones can be attributed to chlorite dehydration.

Lattice-preferred orientations of glaucophane, zoisite, and epidote in zoisite-epidote blueschist from Río San Juan metamorphic complex, Dominican Republic

Yong PARK[1]*, School of Earth and Environmental Sciences, Seoul National University, Seoul 08826, Republic of Korea (dark2444@snu.ac.kr)
Seungsoon CHOI[2], Research Center for Geochronology & Isotope Analysis, Korea Basic Science Institute, Cheongju 28119, Republic of Korea
Seokyeong HAN[3], School of Earth and Environmental Sciences, Seoul National University, Seoul 08826, Republic of Korea
Haemyeong JUNG[4], School of Earth and Environmental Sciences, Seoul National University, Seoul 08826, Republic of Korea

Abstract

To understand deformation mechanisms and developments of lattice-preferred orientation (LPO) of minerals in the subducted oceanic crust, deformation microstructures of naturally deformed zoisite-epidote blueschists (high pressure metabasites) from Río San Juan metamorphic complex in Dominican Republic were studied. LPOs of minerals were determined using the electron backscattered diffraction (EBSD) technique, and intracrystalline deformation microstructures were observed by high-resolution EBSD mapping. The LPOs of amphiboles (glaucophane and barroisite) mostly showed that the [001] axes were aligned subparallel to the lineation and the [100] axes were aligned subnormal to the foliation. The LPOs of zoisites showed that the [010] axes were aligned parallel to the lineation and both [100] and [001] axes were distributed in a weak girdle shape perpendicular to the lineation with clusters aligned normal to the foliation. The LPOs of epidotes mostly showed that the (010) poles were aligned subparallel to the lineation with girdle distribution parallel to the foliation and the [100] axes and/or [001] axes were aligned subnormal to the foliation. The misorientation less than 1º along the chemical composition boundary between sodic (glaucophane) to sodic-calcic (barroisite) amphibole in a single grain suggests that the transition of the chemical composition can moderately affect the tilting of the crystal lattice. However, the dominant misorientation lines, independent of the chemical transition boundary, suggest that the main development mechanism of the LPO of amphibole is likely to be a deformation in dislocation creep. The high density of subgrain boundaries and high grain reference orientation deviation (GROD) angles in zoisite porphyroclasts suggest that they were deformed by dislocation creep and developed LPO with strong fabric strength. The small amount of subgrain boundaries, weak fabric strength, and low grain orientation spread (GOS) values of epidote aggregates, which are regarded as the porphyroclastic lawsonite pseudomorph, suggest that LPO of epidote in aggregates might not have been developed by the recrystallization of epidote porphyroclast in dislocation creep. Instead, the LPO of epidote in these aggregates is likely to be developed through the metamorphic transition from lawsonite to epidote, following the pre-existing subgrain boundaries of the lawsonite porphyroclast. These results suggest that although the subducted oceanic crust metamorphosed under similar blueschist-facies condition,

main deformation mechanism, which develops the LPO of the constituent minerals, can vary due to the rheological heterogeneity among these minerals.

All six typical olivine CPO types discovered in single research area and its seismic implications

Yilun Shao[1]*, Jilin University (ylshao@jlu.edu.cn)
Marianne Negrini[2], 2Department of Geology, University of Otago, Dunedin 9054, New Zealand
Cai Liu[3], 1College of Geoexploration Science and Technology, Jilin University, Changchun 130026, China
Rui Gao[4], 3School of Earth Science and Engineering, Sun Yat-Sen University, Guangzhou 510275, China

Abstract

Generally, olivine exhibits six primary crystallographic preferred orientation (CPO) types (i.e., A-E and AG-type). It has long been believed that these fabrics arise from various environmental conditions, such as different pressure, temperature, water content, stress, and the presence of second phases. Conversely, mantle undergoes multiple deformation events may exists multiple types of olivine CPO, often associated with grain size reduction. In the Red Hills Massif (part of the Dun Mountain Ophiolite Belt) in northern South Island, New Zealand, all six olivine CPO types have been discovered within a 1 km square research area, exhibiting similar coarse-grained textures. This unique occurrence suggests that the latest simple shear, in conjunction with the presence of second phases (orthopyroxene or spinel) and hydrous environment, has contributed to these deformation characteristics. Given that seismic velocities and anisotropies in the mantle correlate with olivine CPO, it is plausible that the dominance of olivine B/C/E-types could result in weakened seismic properties. Furthermore, the direction of SKS splitting is also influenced by olivine CPO. For instance, if B-type olivine CPO were predominant, the actual direction of mantle flow would be normal to the SKS direction. Consequently, seismic data may exhibit ambiguities under microstructural view. The discovery of all six typical olivine CPO types further exacerbates the potential ambiguities within the natural mantle. To improve our understanding of mantle flow processes, it is crucial to conduct detailed research on olivine CPO data alongside related seismic data. This interdisciplinary approach is essential for better comprehending the complexities of mantle geodynamics and seismic behavior.

Differential Stress Affecting Preservation of Intergranular Coesite in UHP Rocks from the Dabie Shan: Ultra-microstructure Insights from TEM

Jinyu ZHENG[1]*, School of Earth Sciences, Chinua University of Geosciences (gemfisher@cug.edu.cn)
Tao CHEN[2], Gemmological Institute, State Key Laboratory of Geological Process and Mineral Resource, China University of Geosciences
Junfeng ZHANG[3], School of Earth Sciences, State Key Laboratory of Geological Process and Mineral Resource, China University of Geosciences
Wenlong LIU[4], School of Earth Sciences, State Key Laboratory of Geological Process and Mineral Resource, China University of Geosciences
Feng SHI[5], School of Earth Sciences, State Key Laboratory of Geological Process and Mineral Resource, China University of Geosciences

Abstract

Coesite is a key indicator mineral in ultrahigh-pressure (UHP) metamorphic rocks. The local “dry” environment provides an explanation for the preservation of intergranular coesite during continental exhumation from the reaction kinetics. However, the deformation behaviors of coesite and surrounding minerals at the ultra-microstructural scale remains poorly understood. In this study, electron backscatter diffraction (EBSD), focus ion beam (FIB), and transmission electron microscopy (TEM) techniques were used to investigate the ultra-microstructure of intergranular coesite and surrounding minerals in a metasedimentary rock from the Ganjialing area of the Dabie Shan region, China. Our findings reveal that coesite exhibits no intracrystalline deformation or dislocation. In contrast, dolomite and apatite adjacent to coesite exhibit much higher density of dislocation compared to those away from coesite. Furthermore, retrograde palisade quartz rimming the coesite displays high dislocation density and tangles. The calculated differential stress based on the free dislocation density indicating that the palisade quartz underwent high differential stress. Dolomite and apatite form a closed system that encloses the coesite, while the palisade quartz is strengthened through work-hardening induced by dislocations, forming a protective buffer crust around the coesite. This closed system acts as an excellent container, preserving the differential stress recorded by the palisade quartz during the survival of coesite. The required pressure for coesite to back-transform into quartz is reduced under differential stress conditions, enabling the preservation of coesite under lower lithostatic pressures during the exhumation of deeply subducted continental. The observations of the ultra-microstructure confirm the presence of differential stress in the surrounding minerals, highlighting its crucial role in the preservation of intergranular coesite. The study of differential stress may serve as a suitable approach for investigating the formation and preservation environments of other UHP minerals, providing valuable insights into the processes involved in the exhumation of deeply subducted continental crust.

Abstract

Constraining the stress related to lithospheric deformation in natural rocks is key to develop and test a geodynamic model. However, the cautions of extrapolating piezometers that are established on experimental samples to natural rocks are less addressed. In this study, we investigated the microstructures of a natural harzburgite sample using the electron backscatter diffraction (EBSD) technique. The geometries of subgrain boundaries (SGBs) unveiled a preponderance of (010)[100] and {0kl}[100] dislocation slip systems in olivines. More importantly, multiple low-angle misorientation boundaries (LAMBs) variants are recognized for the first time in olivine based on their distinctive characteristics with the change of EBSD mapping step size. The LAMBs that exist at a small step size (≤ 1 μm) are mostly equivalent to real SGBs, while other LAMBs that appear only when the step size is larger (> 1 μm) are artificial SGBs. Besides, the former develop mainly in the high LAMB density grains, whereas the latter are mostly found in the low LAMB density grains. This revelation corroborates the prevailing understanding that stress calculations derived from subgrain-related piezometers are meaningful only when authentic SGBs are captured at sufficiently minuscule step sizes. Furthermore, we provide a proof of concept that SGB density and kernel average misorientation (KAM) are two viable metrics to estimate stress. These two alternative piezometers, which still need calibrations using the experimentally deformed samples, are anticipated to have wide applications in natural rocks.

PROGRESSIVE STRAIN LOCALIZATION AND FLUID-ASSISTED DEFORMATION IN MANTLE EXHUMATION DURING RIFTING: PETROSTRUCTURAL CONSTRAINTS FROM THE ZABARGAD PERIDOTITES, RED SEA)

Mérope Anne CHARDELIN[1]*, CNRS/Université de Montpellier (m-chardelin@caramail.fr)
Andréa Tommasi[2], CNRS
José Alberto Padron Navarta[3], Instituto Andaluz de Ciencias de la Tierra

Abstract

The three peridotite massifs in the Zabargad island (northern Red Sea) document the exhumation of the mantle during continental rifting and the rift to drift transition. Deformation evolved from pervasive at the massif scale to localized in metric shear zones. To characterize the active processes and the role of melts and aqueous fluids in the deformation, we performed a petrostructural study of 40 samples representative of the different stages of deformation in the three massifs. Microstructures recording synkinematic crystallization of plagioclase, clinopyroxene, and orthopyroxene in the southern and amphibole-bearing spinel-websterite layers in the central and northern massifs indicate that pervasive deformation occurred in the presence of melts, but at lower pressure in the south. In the shear zones, deformation was accommodated by concomitant dislocation and dissolution-precipitation creep. Evolution from protomylonites to ultramylonites produced increasing volumes of a fine-grained polymineralic matrix where amphibole progressively replaces plagioclase and clinopyroxene. Fluid-assisted deformation at all stages is attested by the interstitial shapes of pyroxene neoblasts intermixed with olivine in the matrix. Local deformation at the brittle-ductile transition is accompanied by the crystallization of scapolite. Thermobarometry and thermodynamic modelling constrained by the microstructural observations document shearing under decreasing pressure and temperature from near solidus conditions at >1 GPa in the north and central massifs and ~0.7 GPa in the southern massif to < 600°C and <0.3 GPa in all three massifs. These data also imply increasing hydration, indicating fluid focusing and local aqueous fluid saturation in the shear zones, with sea water ingression to >10 km depth. However, fluid supply was spatially heterogeneous and probably intermittent, with equilibrium only achieved locally in the ultramylonites. The present study documents therefore how progressive strain localization and fluid-focusing in extensional shear zones enable thinning and exhumation of the mantle during continental rift and rift-to-drift transition.

This work was supported by the European Research Council (ERC) under the European Union Horizon 2020 Research and Innovation programme [grant agreement No 882450 – ERC RhEoVOLUTION].

Rheological inhomogeneities in the geodinamic structures of the earth' s crust

GENNADY ERMOLAEV[1]*, IMR (egs25@mail.ru)

Abstract

ERMOLAEV G.S.
RHEOLOGICAL INHOMOGENEITIES IN THE GEODINAMIC
STRUCTURES OF THE EARTH'S CRUST

Numerous inhomogeneities identified during the studythe study of continents, oceans and ore objects, contributed to an in-depth analysis of the material composition to decipher the structure of the Earth. «The material composition of geological formations determines not only the morphology,but also the most important tectonic(geodynamic) features»(V.P.Fedorchuk,1921-2011).

The study of ore deposits of Central Asia (Northern, Central and Southern Tien Shan) through the science of RHEOLOGY to combine tectonics, geophysics, geochemistry, geomorphology and establish a geodynamic relationship between form and content, space and time, to determine the decisive the role of endogenous forces in the formation of geomorphostructures of the Earth.

Continents and oceans, platforms and mobile belts, ore and barren areas, represent rheological heterogeneities. They appear in the form of structural (rigid-block) and structureless (plastic-inextricable) formations.

Within the Tien Shan, hard formations - terranes make up predominantly elevated areas of the relief. Plastic-continuous ones (mainly silt-shales) correlate with its leveled part. The ore mineral complex occupies an intermediate position, located on the boundaries of the pre-Mezozoic and Meso-Cenozoic, often associated with the boundaries of elevated and leveled relief.

These patterns are reflected in the cartographic material of geological, geophysical, geochemical, geomorphological studies and satellite photographs.They represent the post-Alpine fault-block tectonic flow of rock masses, including ore ones.

The driving force is siltstone-shale, thermodynamic plastic geomass. Originating in the bowels of the Earth, it penetrates the rift structures of the mid-ocean ridges, causing spreading of the ocean floor and rupture, of the continental crust. A similar relationship has been established between the complex system of the Mid-Arctic ridges and the central part of the continent of Eurasia, in which stretching processes occur.

The interaction of subcrustal (plastic) and crustal (hard) formations forms melange complexes (schist or ophiolite). Similar complexes make up most of Central Asia.

The conditions the disband of geological structures, including ore ones, have been established. This is due to the horizontal extension of the Earth's crust in the post-Alpine time, the rise of hot depth matter and its lateral movement (flow) along the fracture marked from the surface of the Mesozoic-Cenozoic sediments. This is manifested in the interaction of the arcuate structures of the Tien Shan with the Indian plate.

Their movements in a southerly direction contribute to a collision with each other. The structures

of the Tien Shan, like small blocks, unfold, stratify, and move apart, facilitating the penetration of siltstone-shale geomass, causing earthquakes and complicating the structural plan of the region.
The Central Tien Shan and the southwestern spurs of the Gissar ridge are commensurate with each other and, as it were, connect into a single whole the arc-shaped structures of the Northern and Southern Tien Shan and Kopetdag. Under compression conditions, they form a single mountain system vertically.
Rheological processes are evidence of the evolutionary development of the Earth and the geodynamic interaction of crustal and subcrustal formations in conditions of its expansion.

Evolution of Deformation Microstructures and Fluid Inclusions in Peridotite Xenoliths beneath the Rio Grande Rift

Munjae PARK[1]*, Chungbuk National University (mpark@cbnu.ac.kr)

Abstract

Mantle heterogeneity is closely related to the distribution and circulation of volatile components in the Earth's interior, and the behavior of volatiles in the mantle strongly influences the rheological properties of silicate rocks. In mantle xenoliths, these physicochemical properties of the upper mantle can be recorded in the form of microstructures and fluid inclusions. In this paper, I summarized and reviewed the results of previous studies related to the characteristics of microstructures and fluid inclusions from peridotite xenoliths beneath the Rio Grande Rift (RGR) in order to understand the evolution and heterogeneity of upper mantle. In the RGR, the mantle peridotites are mainly reported in the rift axis (EB: Elephant Butte, KB: Kilbourne Hole) and rift flank (AD: Adam's Diggings) regions. In the case of the former (EB and KB peridotites), the type-A lattice preferred orientation (LPO), formed under low-stress and low-water content, was reported. In the case of the latter (AD peridotites), the type-C LPO, formed under low-stress and high-water content, was reported. In particular, in the case of AD peridotites, at least two fluid infiltration events, such as early (type-1: CO2-N2) and late (type-2: CO2-H2O), have been recorded in orthopyroxene. The upper mantle heterogeneity recorded by these microstructures and fluid inclusions is considered to be due to the interaction between the North American plate and the Farallon plate.

Tectonic characteristics and petroleum geological significance of the CiCun fault

Jun YANG[1]*, China University of Petroleum (East China) (2735942419@qq.com)
Li LI[2], China University of Petroleum (East China)

Abstract

The complex fault system had been formed in Luxi block due to multi-stage tectonic activities. The CiCun fault was one of the many radial faults in the north of the Luxi block, which extended northward into the Dongying Depression and connected to the faults in the oil zone. There are few researches on the CiCun fault in the past, so this paper uses the method of structural analysis to clarify the tectonic characteristics of the CiCun fault and analyze its petroleum geological significance based on the field outcrop data and indoor rock slices.

The CiCun fault was a right-lateral extension-strike-slip fault with a nearly north-south strike and a large east dip. The structure derived from the two plates of the fault was relatively developed. The scratches with a strike of 105° can be seen in the limestone strata of the western plate of the fault, which reflects the characteristics of left-lateral fault activity. Two sets of conjugate fractures with a strike of 203° and 143° can be seen in the carboniferous siltstone on the western side of the fault. The sharp Angle points to 173°, indicating that it is compressed from south to north, corresponding to the stress field of the Indochinese period. Two groups of joints are also visible in this formation, with strike of 110° and 187° respectively, indicating the NW-SE compression, corresponding to the early Yanshan stress field. To sum up, the CiCun fault was formed in the Indochinese period and was dominated by sinistral strike-slip, then experienced the compression-torsion sinistral strike-slip in the early Yanshan period, and became a right-lateral extension-strike-slip fault dominated by strike-slip in the Cenozoic due to the influence of the Tanlu fault zone.

Field samples of the CiCun fault zone were observed under microscope, and a certain number of hydrocarbon inclusions showed two different colors under fluorescence irradiation, indicating the existence of two kinds of hydrocarbons with different maturity, which is similar to the oil-gas geochemical characteristics of the Pingnan fault in Dongying Depression. It can be concluded that the CiCun fault was once a migration channel for oil and gas, and some oil and gas in Dongying Depression migrated to the Luxi block along the CiCun fault. The northern part of the Luxi block may be a potential area for oil and gas.

Deformation microstructures of blueschists in Alpine Corsica, France, and implications for seismic properties in subducting oceanic crust

Seungsoon CHOI[1]*, Korea Basic Science Institute (sechoi1@kbsi.re.kr)
Yong Park[2], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea
Seokyoung Han[3], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea

Olivier Fabbri[5], Université de Franche-Comté, Besançon, France
Haemyeong Jung[6], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea

Abstract

Understanding the deformation microstructures and seismic properties of blueschists is crucial for interpreting seismic anisotropy and low velocity layer at the top of cold and warm subducting oceanic crust. In this study, we investigated the deformation microstructures and seismic properties of epidote blueschist, epidote-lawsonite blueschist, and lawsonite blueschist from Alpine Corsica, France. The crystal preferred orientations (CPOs) of glaucophane exhibited the strong maximum of [001] axes aligned sub-parallel to the lineation, while the maximum of (010) poles of epidote was aligned sub-parallel to the lineation. The [001] axes of lawsonite were strongly aligned sub-normal to the foliation. Intracrystalline misorientations and dislocations of glaucophane and epidote suggest that the CPOs of glaucophane and epidote were mainly developed through dislocation creep. In contrast, the existence of subhedral to euhedral-shaped, foliation-parallel aligned long axis of lawsonites, as well as misorientations and twins in lawsonites, indicate that the lawsonite CPO was developed by a combination of rigid body rotation and dislocation creep, with a minor effect of lawsonite twins. The seismic anisotropies of the blueschists showed higher P-wave anisotropy (AVp) and maximum S-wave anisotropy (max.AVs) in epidote blueschists (AVp = 12.3–16.9% and max.AVs = 6.53–11.75%) than in lawsonite blueschists (AVp = 8.9–9.1% and max.AVs = 4.44%). The seismic velocities of the blueschists ranged from 8–12% for P-wave and 10–14% for S-wave, which are lower than those of mantle peridotites. These values are comparable to those of low velocity layers in modern subduction zones. The coexistence of epidote and lawsonite in the blueschist resulted in various seismic anisotropies and P-wave velocity of the whole rock, depending on the modal content of epidote and lawsonite. A high content ratio of epidote to lawsonite in blueschist produced strong P- and S-wave anisotropies when the glaucophane content exceeded ~50%. P-wave velocity of blueschist linearly decreased with increasing epidote content. Our results suggest that the seismic properties of deformed blueschist can contribute to the seismic anisotropy and low velocity layer in subducting oceanic crusts in subduction zones.

Petrofabrics and microstructures of phyllite from Geumseongri Formation, South Korea: Implications for seismic anisotropy

Seokyoung HAN[1]*, School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea (hs04111@snu.ac.kr)
Haemyeong JUNG[2], School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea

Abstract

Minerals in mica group exhibit the strongest seismic anisotropy in continental crust, subducting slab, and upper mantle in subduction zone. Alignment of mica significantly influences magnitude and symmetry of seismic anisotropy, especially when seismic wave passes through a rock composed of mica more than 20-40%. Therefore, analyzing mica-rich natural rocks is crucial to investigate the origin of seismic anisotropy observed in nature. In this study, muscovite-quartz phyllites from Geumseongri Formation in South Korea were analyzed using Electron Backscattered Diffraction (EBSD) to measure lattice preferred orientation (LPO) of minerals. The samples are mainly composed of muscovite, quartz, albite, chlorite, and biotite with minor calcite and rutile. The EBSD analysis showed that the muscovite [001] axis was strongly aligned normal to the foliation while both [100] and [010] axes were dispersed parallel to the foliation. Chlorite and biotite also exhibited similar LPO except for the chlorite [001] axis in the sample G102, dispersed normal to the lineation. LPOs of quartz showed combinations of basal<a>, rhomb<a>, prism<a> slip system. The albite (010) pole or (001) pole was aligned subnormal to the foliation. Seismic anisotropy was calculated based on the LPO and modal composition of the samples. The anisotropy of P-wave (Vp) for quartz was in the range of 4.3 - 9.3% and 3.3 - 6.7% for albite. The maximum shear wave anisotropy (AVs) was in the range of 5.3 - 11.2% for quartz and 3.9 - 5.4% for albite. The Vp anisotropy and maximum AVs anisotropy of mica were in the range of 19.3 - 53.4% and 11.6 - 62.9%, respectively, which are much larger than those of other minerals. As a result, the Vp and maximum AVs anisotropy for whole rock were in the range of 11.8 - 44% and 11.6 - 51.8%, respectively. These results show that modal composition and alignment of mica mainly control the magnitude and symmetry of seismic anisotropy.

Microstructures of deformed granites and calc-silicate rocks in Yeoncheon, South Korea

Sena SIM[1]*, School of Earth and Environmental Sciences, Seoul National University , Seoul, Republic of Korea (senasim@snu.ac.kr)
Haemyeong JUNG[2], School of Earth and Environmental Sciences, Seoul National University , Seoul, Republic of Korea

Abstract

Quartz is one of the major constituent minerals of the crust. To understand the deformation mechanisms of quartz, we studied mylonitized granites and calc-silicate rocks from Yeoncheon in the Gyeonggi Massif, South Korea. Crystal preferred orientation (CPO) of quartz in the samples was measured using the scanning electron microscope (SEM) with electron backscattered diffraction (EBSD) facility. Recrystallized quartz grains were identified using the grain orientation spread (GOS) derived from the EBSD analysis. The mylonitized granites predominantly consist of quartz (41 - 45%), plagioclase (35 - 49%), and alkali feldspar (5 - 23%), while the calc-silicate rocks consist of quartz (25 - 40%), plagioclase (40 - 54%), alkali feldspar (19 - 20%) with a small amount of biotite. EBSD analysis showed that c-axes of quartz in the mylonitized granites are aligned subnormal to the lineation and parallel to the foliation, indicating a prism <a> slip system of quartz. The poles of the (11-20) plane of quartz were aligned parallel to the lineation. In contrast, the c-axes of quartz in the calc-silicate rocks were distributed as a girdle subnormal to the lineation, which are considered to have been influenced by the rhomb <a> and prism <a> slip systems of quartz. The observations of the CPOs of quartz and the resultant slip system indicate that the mylonitized granites were deformed at a moderate temperature (~400 - 550 °C), while the calc-silicate rocks were deformed at low temperature (~300 - 500 °C). The recrystallized grain size of quartz was 47 μm on average for the mylonitized granites and 28 μm for the calc-silicate rocks, indicating that the granites and calc-silicate rocks were deformed at differential stresses of approximately 46 MPa and 57 MPa, respectively. A thorough study of the microstructures of other constituent minerals such as plagioclase, alkali feldspar, and biotite, in addition to quartz, is crucial for a complete understanding of the deformational processes of the rocks in the study area.

Lattice-preferred orientation and deformation mechanisms of amphibole in amphibolites from Jenner Headlands, Sonoma County, and Ring Mt., Marin County, California, U.S.A.

Junha KIM[1]*, Seoul National University (ratoria1001@snu.ac.kr)
Haemyeong Jung[2], Tectonophysics Laboratory, School of Earth and Environmental Sciences, Seoul National University, Seoul, Republic of Korea
Loren A. Raymond[3], Department of Geology, Appalachian State University, Boone, NC, U. S. A.

Abstract

The microstructures and deformation mechanisms of amphibole significantly impact the overall structure and deformation processes of the crust because amphibole occupies a large volume fraction in the middle to lower crust. Amphibole is elastically very anisotropic, therefore, lattice-preferred orientation (LPO) of amphibole can largely affect the characteristics of seismic wave propagation in the crust, particularly seismic anisotropy. In this study, we collected and analyzed amphibolites from Jenner Headlands and Ring Mt. in the Franciscan Complex in Western California. LPO of amphibole was measured using scanning electron microscope (SEM) with electron back-scattered diffraction (EBSD) facility. The SEM and transmission electron microscope (TEM) were used to study microstructureal detail and deformation mechanisms of amphibole. All samples were well-foliated amphibolites which consist mainly of amphibole, plagioclase, and minor minerals such as garnet, epidote, mica, and titanite. The type-III LPOs of amphibole were observed in all samples, which is characterized as the [100] axes of amphibole aligned normal to the foliation and the [001] axes forming a girdle distribution on the foliation (refer to the classification of amphibole LPO type by Ko and Jung, 2015). The calculated grain orientation spread (GOS) of samples exhibited consistently low values for all the samples. Furthermore, observations of samples using the SEM and TEM indicate that the deformation mechanism of amphibole involves cataclastic flow with rigid body rotation and dissolution-precipitation creep. In addition to these deformation mechanisms, it is found that topotactic growth of amphibole from clinopyroxene also influenced the development of the type-III LPO of amphibole. The observed deformation mechanisms of amphibole within the Franciscan mélange in W. California provide insights into understanding the deformation processes within subduction zones.

High-temperature shear initiation of subridge mantle: A microstructural study of peridotites from the Zhongba ophiolite, SW Tibet

ZHANG ZHEN[1]*, University of Chinese Academy of Sciences (zhangzhen184@mails.ucas.ac.cn)
Liu Chuan Zhou[2], Laoshan Laboratory, Qingdao
Jung Haemyeong[3], Seoul National University
Jung Sejin[4], Seoul National University
Liu Tong[5], Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

Strain localization is the fundamental prerequisite for shear zone development in rheologically weak regions, such as the detachment faults at slow to ultra-slow spreading ridges. How does strain localization initiate within subridge mantle at high temperature (i.e., the sub-solidus conditions) is still poorly understood, which instead is more easily facilitated at low temperature. To understand the mechanisms for triggering this process, we analyzed mineral H2O contents and microstructures for fresh mantle harzburgites from the Zhongba ophiolite in the Yarlung-Tsangpo Suture Zone in terms of its petrological and variable-deformation advantages. Porphyroclastic peridotites and mylonites are both equilibrated at consistently high temperature (972-1185ºC), low oxygen fugacity (-0.93) conditions. Low H2O contents (48–107 wt. ppm) in orthopyroxene mainly controlled by partial melting represent the original water contents in a depleted mantle comparable to the ultraslow spreading ridges. Electron backscattered diffraction (EBSD) analysis revealed that crystal preferred orientation of olivine (Ol) and orthopyroxene (Opx) switch from mantle flow (Ol: A- and E-type; Opx: AC-type) to shear zone (Ol: D-type; Opx: CA-type) as deformation proceeds. Progressive grain size reduction causes successive decrease in fabric strength and promote strain rate for over two orders of magnitude (from ~10-14 s-1 to >10-12 s-1). Concurrently, deformation mechanisms convert dislocation creep to grain boundary sliding (GBS) and ultimately to diffusion creep from low-stress regimes (5.8-8.8 MPa) to high-stress regimes (up to 37.5 MPa). Combined with rheological modelling using olivine flow laws, we proposed a scenario depicting the petrological and textural evolution as well as mutually microstructural feedback with ongoing strain localization in detail. Our findings show that CPO transition and grain size reduction (GRS) can play a key role in shear initiation of subridge mantle at high temperature, especially for the melt-starved mid-ocean ridges.

Crystallographic preferred orientation and seismic anisotropy of minerals in glaucophane schist and eclogite from the Franciscan Complex of Jenner, California

Yoonhae HA[1]*, School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea (gkyoon0507@snu.ac.kr)
haemyeong JUNG[2], School of Earth and Environmental Sciences, Seoul National University, Seoul, Korea

Abstract

Strong seismic anisotropy observed in many subduction zones is partly attributed to subducting oceanic crust. Glaucophane schist forms a major proportion of the top of the slab and commonly transforms to eclogite during subduction. Studying crystallographic preferred orientation (CPO) of glaucophane schist and eclogite forming minerals could be crucial to understand the seismic properties observed in the subducting slab and channel. We studied deformation microfabrics and seismic properties of glaucophane schist and eclogite from the Franciscan Complex of Jenner, California. Glaucophane schist samples are mainly composed of glaucophane, epidote and phengite. Eclogite samples are mostly composed of omphacite, glaucophane and garnet. CPOs of minerals were measured by using the FE-SEM/EBSD and we calculated seismic properties of major minerals and whole rocks.

In most samples, the CPO of glaucophane showed that [001] axes are aligned sub-parallel to lineation with a girdle parallel to foliation. Both (110) poles and [100] axes are aligned subnormal to foliation. Epidote showed that the [001] axes are aligned subnormal to foliation and both (110) and (010) poles subparallel to lineation. CPOs of phengite were characterized by a maximum of the [001] axes aligned normal to foliation, with the (110) and (010) poles and [100] axes aligning in a girdle parallel to foliation. CPOs of omphacite showed that the [001] axes are aligned subparallel to lineation and the [010] axes subnormal to foliation. Major minerals in glaucophane schist showed a strong seismic anisotropy. Especially, phengite showed the strongest seismic anisotropy (AVP = 15 — 52 %, max.AVS = 11 — 52 %). In contrast, omphacite and garnet showed very weak seismic anisotropy. As a result of whole rocks, glaucophane schist showed much stronger seismic anisotropy than eclogite facies rocks. Therefore, strong seismic anisotropy observed in subduction zone could be more affected by glaucophane schist, especially phengite-rich glaucophane schist, rather than eclogite.

Deep Structure of the Southeast Asian Curved Subduction System and its Dynamic Process

Weiwei Ding[1]*, Second Institute of Oceanography, MNR, China (wwding@sio.org.cn)
Jiabiao Li[2], Second Institute of Oceanography, MNR, China
Xiongwei Niu[3], Second Institute of Oceanography, MNR, China

Abstract

The main reason for the habitability of the Earth is the presence of an active interior, in which subduction zones play an important role. As linear subduction zones continue to evolve and form highly curved shape, the original plate morphology, deep structure, and convection patterns will undergo significant changes, leading to increasingly complex dynamic mechanisms and giving rise to a series of new problems that current plate tectonic theories find difficult to explain. Southeast Asia is a typical representative of an inward-curved subduction system. The deep structure, material circulation, and dynamic processes in the Southeast Asia have long been an elusive scientific puzzle due to the lack of systematic scientific observations and recognized theoretical models. Based on the deep seismic tomography using long-period natural earthquake data, this study investigates the deep structure and material circulation of the curved subduction system in Southeast Asia, and reconstructs the dynamic processes since 100 million years ago. It is pointed out that challenges still exist in the precise reconstruction of deep mantle structures in the study area, the influence of multi-stage subduction on deep material circulation and shallow magma activity, as well as the spatiotemporal evolution and coupling mechanism of multi-plate convergence. Future work should focus on high-resolution land-sea joint three-dimensional seismic tomography imaging of the curved subduction system in Southeast Asia, combined with geochemical analysis and geodynamic modelling works.

Influence of Convergence Rate and Subduction Dip Angle on Island-Arc Magma Production

Yongliang BAI[1]*, China University of Petroleum (East China) (ylbai@upc.edu.cn)

Abstract

Island-arc growth is a primary outcome of the subduction system, offering valuable insights into subduction dynamics. Understanding how key factors impact island-arc growth is crucial for uncovering these dynamics. This study aims to investigate how convergence rates and slab dip angles influence the production rate of island-arc magma (MPR) using numerical models.

The simulations were conducted using ASPECT to model various processes, such as slab penetration, mantle convection, slab dehydration, water migration in the wedge, mantle partial melting, and melt extraction. The coverage rate and subduction dip angle of our numerical models varies between 2 cm/yr and 10 cm/yr, between 30° and 60°, respectively. These ranges can cover the majority subduction zones according to the variations of the convergence rates and subduction dip angles of the present subduction zones on the Earth. The findings indicate the following trends: (1) Increasing convergence rates lead to higher mean and peak MPR values. (2) As the slab dip angle increases from 30° to 45°, both mean and peak MPR values increase. However, when the dip angle continues to increase from 45° to 60°, mean and peak MPR values start to decrease. (3) The convergence rate has a more significant influence on MPR compared to the dip angle.

The influence of convergence rate and slab dip on island-arc MPR is based on their effects on mantle wedge temperature and hydration fraction. Specifically: (1) An increase in convergence rate leads to higher mantle wedge temperature and hydration fraction during both MPR increasing and decreasing periods. (2) Similarly, an increase in slab dip angle leads to higher mantle wedge temperature during both MPR increasing and decreasing periods. However, the impact on hydration fraction differs. Specifically, hydration fraction initially increases and then decreases as the slab dip angle increases from 30° to 45° and subsequently from 45° to 60°. As hydration fraction has a more significant impact on mantle melting than temperature, MPR increases as the slab dip angle increases from 30° to 45° but decreases as the slab dip angle increases from 45° to 60°.

How could density contrast between magmatic rocks and bedrocks affect SDR formations?

Haibin YANG[1]*, Zhejiang University (haibin.yang@zju.edu.cn)
Huixin Guan[2], Key laboratory of ocean and marginal sea geology, Chinese Academy of Sciences

Abstract

Seaward dipping reflectors (SDRs) are characteristic features to identify a volcanic passive margin. They usually form sets of wedges developing with time from the inner- to the outer-part of the necking zone . They are first identified as layered igneous sequences dipping towards the ocean from multi-channel seismic reflection profiles offshore the North and the South Atlantic margins. Two sets of SDRs, inner SDRs and outer SDRs, can be distinguished according to their location and geometry. They generally show the same seaward-developing divergent-arcuate pattern. Outer SDRs usually present smaller thickness (less than 2km) and no wedge shape , while inner SDRs are usually constitute of several seaward dipping convex-wedges and the thickness of a single inner SDR wedge commonly varies from 5 to 10 km. How these structures are developed is not yet clear. We use numerical models to show that the density contrast between surfacial magmatic rocks and bedrocks, together with hot and weak lower crust , can create similar structures as SDRs in a volcanic passive margin. It can explain different structures between SDRs and sedimentary basins. High density contrast tends to promote faults develops towards the sea and generate continent-dipping normal faults in passive volcanics margins.

Structure and geodynamics beneath the Indian Ocean inferred from multimode surface wave tomography

Debasis D MOHANTY[1]*, Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, Sapporo, Japan (devlinkan06@yahoo.com)
Kazunori Yoshizawa[2], Department of Earth and Planetary Sciences, Faculty of Science, Hokkaido University, Sapporo, Japan

Abstract

Multimode surface wave tomography provides a robust spatial image of the Earth's upper mantle over a wide depth range, dealing with a broader frequency range of waveform records. We have created new tomographic images of multimode phase speeds of Rayleigh and Love waves in the Indian Ocean with recently enhanced seismic networks in the southern hemisphere by incorporating a large number of regional surface-wave paths for both the fundamental and higher modes, which are sensitive to the whole upper mantle structure. With a data set of 22 years, we have retrieved more than 63,000 and 26,000 ray paths for fundamental Rayleigh and Love waves, respectively, over a wide period range (30 s – 200 s), where more than 16,000 ray paths are achieved for successful analysis of higher modes. In the first stage, the multimode waveform inversion is performed to compute path-specific 1-D velocity profiles to retrieve the dispersion information. In the second stage, the information from all the ray paths is combined to produce multimode phase speed maps with an approximation of surface wave propagation along great circle paths. These phase speed maps are further updated by incorporating the ray tracing and finite frequency effects along the influence zone around the corresponding surface wave path. We have produced high-resolution phase-speed maps beneath the Indo-Australian plate, which indicate some intriguing structural features, such as the relatively faster anomaly underneath the Australian Antarctica Discordance and the relatively slower anomaly along the Ninety East Ridge. These multimode phase speed maps will be used to construct the final 3D model as the final stage of our tomography model. This three-stage inversion process, including automated multimode phase speed measurements with a fully non-linear waveform fitting, and subsequent phase speed mapping incorporating ray-bending and finite-frequency effects, has significant benefits in improving the model images in regions with tectonic complexity and significant lateral velocity gradients, such as near tectonic boundaries along continent-ocean margins and subduction zones, Indo-Eurasian collision, Indo-Burmese arc, and mid-ocean ridges in the Indian Ocean.

The structure and spreading history of the South China Sea

Zhen SUN[1]*, South China Sea Institute of Oceanology (zhensun@scsio.ac.cn)
Ning Qiu[2], South China Sea Institute of Oceanology
Weiwei Ding[3], Second Institute of Oceanography, Ministry of Natural Resources,

Abstract

As one of the largest marginal seas in the Western Pacific, the South China Sea experienced an almost complete Wilson cycle. Therefore, the research on its evolution could provide an important reference to the other marginal sea basins. However, strong controversies exist in the spreading history of the South China Sea, especially on the location of the fossil ridge, and the periods as well as mechanism of ridge jump. In order to deduce the spreading history of the SCS accurately and decode the mechanism of ridge jump in marginal sea basins, we first lock down the location of the latest fossil ridge with both OBS velocity and free air gravity anomaly, at the same time the spreading direction as well as the fracture zone direction were confirmed with the macrostructure analysis from IODP drilling sites U1431 and U1433. Expanded from the latest spreading stage, we obtained the whole spreading history according to spreading fabrics based on high resolution bathymetry and magnetic anomaly lineation. The fracture zone(inactive transform fault) during spreading stage were reconstructed. We found that the spreading direction of the SCS changed frequently during the 16 Myr spreading history. Along with the spreading direction variation, the ridge may rotate or migrate accordingly. Kinematic analysis suggest that the style of ridge adjustment depends on the relative location of spreading ridges and transform fault, as well as the relationship between clockwise or counter clockwise rotation relative to the ridge. Based on these data and kinematic analysis, we realized that ridge adjustment caused by spreading direction variation was proceeded mainly by rotation or slight migration, which can’t explain the whole ridge jump at early Miocene. At the same time, the M-number of the whole South China Sea basin suggest a fundamentally difference before and after early Miocene (~23 Ma). The early Miocene ridge jump is strongly correlated with the magma supply, the later decreased greatly after ridge jump to the south. Therefore, we conclude that the early Miocene Ridge jump might be caused by magma supply event, while the other stage of ridge adjustment might be caused by spreading direction variation.

Abstract

Marginal Seas are extensional basins formed in a convergent setting near active subduction zones. They are characterized by a short life (<25 Ma), as well as unstable and changing directions of seafloor spreading. However, the processes related to their formation from rifting to seafloor spreading initiation remain debated (supra-subduction convection/extension, slab-pull). This problem is further compounded by the fact that our understanding of continental breakup used to be derived from the evolution of magma-poor and magma-rich Continent-Ocean Transitions (COT) of the Atlantic margins.

Here, using high-resolution seismic data we describe the tectono-magmatic processes occurring during continental breakup by investigating the COT structures of three Marginal Seas located in the Western Pacific, namely the South China Sea, the Coral Sea and the Woodlark Basin. These data are completed by drilling results of International Ocean Discovery Program (IODP) expeditions available across the South China Sea COT which provides an insight on sediment facies and thermal maturity.

All three examples record a similar pre-rift evolution characterized by an orogenic phase quickly followed by an orogenic collapse with significant influence on the pre-rift inheritance in terms of structures or thermal evolution. Opening of these basins subsequently formed under rapid extension rates and propagation of seafloor spreading. Although each marginal basin is unique, we show that the three of them show a narrow COT (typically <~20 km), where final extension is accommodated by the activity of mainly one low-angle normal fault. Extension is contemporaneous with an important magmatic activity emplaced in the distalmost part of these margins as volcanoes, dikes and sills. This interpretation is confirmed by thermal maturity of sediments showing a jump below post-rift sediments and a higher thermal maturity gradient with respect to depth in the syn-/pre- rift sediments for the SCS. Based on 1D modeling of this dataset, we show that it is necessary to invoke magmatic intrusions in the COT at the time of breakup.

As a result, and unlike in archetypal magma-poor or magma-rich margins, the COTs are characterized by a sharp juxtaposition of continental crust against ”normal” igneous oceanic crust suggesting a rapid shift from rifting to spreading.
Rapid localization of extensional deformation during continental breakup has major implications

for partial melting generation. The evolution of extensional structures is controlled by the interplay of lithospheric thinning, asthenosphere upwelling and decompression melting. High extension rate prevents conductive cooling allowing the focusing of volcanic activity in sharp COTs, quickly evolving to magmatic accretion. Fast extensions rates during the formation of Marginal Seas are likely directed by kinematic boundary conditions directly or indirectly controlled by nearby subduction zones. Such mode of continental breakup is probably not limited to Marginal Seas but only enhanced in such settings.

Detachment fault systems in the Northern South China Sea, insights into 3D tectonic segmentation of rifted margins

Shihao HAO[1]*, China University of Geosciences (haoshihao@cug.edu.cn)
Lianfu Mei[2], China University of Geosciences
César Ranero[3], Institut de Ciéncies del Mar (CSIC), Barcelona, Spain

Abstract

The 2D rifting modes interpreted in traditional “magma-poor” and “magma-rich” margins cannot explain the crustal structure and inferred rifting processes in the northern South China Sea (SCS) rifted margin. The “intermediate-type” terminology has been therefore applied to the mid-northern SCS, where a “wide-rift” model has been widely accepted. However, the tectono-magmatic processes of the SCS are still debated and at least five contrasting interpretation models exist. We present a compilation of 3-D seismic volumes and regional 2-D seismic surveys covering the entire Baiyun and Liwan Sub-basins to investigate their tectonic structure and faulting style in this “wide-rift” region. We interpret two segments with contrasting tectonic styles separated by a volcanic lineament and steep transfer faults. The Baiyun Sub-basin was controlled by a landward-dipping detachment system. The Liwan Sub-basin, however, was formed by a ~100-km-long oceanward-dipping, concave-up detachment system working at a low angle. The lateral boundaries of the detachment system were mechanically decoupled from surrounding tectonics by a volcanic lineament to the west and a >145-km-long N-S-trending left-lateral strike-slip transfer fault to the east. The planar low-angle detachment does not resemble classical metamorphic core complex domes interpreted previously. Our results indicate a 60-80-km-wavelength segmentation within a single “wide-rift” system, indicating complex 3D rifting during crustal extension. This study supports that the intermediate SCS margin had a kinematically complex deformation style locally dominated by the interaction between detachment and transfer fault systems that might be yet unrecognized in other margins.

[Keynote] Hydrothermal Feedbacks on Tectonics During Magma-Poor Rifting and Start of Oceanic Spreading

Marta PEREZ-GUSSINYE[1]*, MARUM/Bremen University (gussinye@uni-bremen.de)
Javier García-Pintado[2], MARUM/Bremen Universität

Abstract

Rifted margins display a wide variety of tectonic architectures and transitions to oceanic spreading. The influence of factors such as extension velocity, initial thermal and rheological profile of the lithosphere and surface processes has been extensively explored in the last two decades. Here, we turn our focus to the largely unknown effect of hydrothermal flow on the temperature field and tectonics during rifting and intiation of seafloor spreading at magma-poor margins. The influence of hydrothermal activity on tectonics has been generally evaluated via a parameterization of the cooling effect from hydrothermal fluid flow in the host rock, emulated by an increase in the thermal conductivity in the heat transfer equation.

Here, we evaluate the feedbacks between hydrothermal activity and tectonics by using a thermo-mechanical model fully coupled with hydrothermal flow, Rift2Ridge_Hydro. Heat release by plastic deformation at fractures and faults, exothermic serpentinization reactions, sensible and latent crystallization heat from magmatic emplacement provide different energy-source signatures promoting hydrothermal activity. We show how advective heat transfer via hydrothermal circulation results in a much higher spatio-temporal variability in the thermal field, in comparison to simulations where this is not considered. In turn, this leads to a strong feedback in the tectonic deformation, the bathymetric relief and the heterogeneity in the composition of the crust in the ocean-continent transition.

Abstract

The Qiongdongnan Basin is located in the northern continental margin of the South China Sea. Since the Cenozoic, the Qiongdongnan Basin has undergone complex tectonic evolution processes, resulting in fault systems comprising normal faults, reverse faults, and strike-slip faults. Although there has been a lot of studies focusing on the Qiongdongnan Basin, the control of fault systems evolution on the spatial and temporal geometric variation have not been well documented. In this research, by employing 3D seismic interpretation and seismic attributes analysis, the stratigraphic contacts and fault systems in Cenozoic were interpreted with high-resolution. The temporal deformation rates of three fault systems were analyzed by calculating the fault offsets versus geological time intervals. The various deformation rates along strikes suggest high level of lateral variation of faulting deformation. By integrating the fault heave/throw distribution maps, the key fault systems were then subdivided into four segments from east to west. Six representative seismic profiles were restored in 2D MOVE, with extension amounts and deformation rates calculated to reveal the Cenozoic structural evolution occurred in the Qiongdongnan Basin. The balanced profile restoration and statistics indicated that the Qiongdongnan Basin experienced a multi-staged evolution, including the Oligocene rifting stage, the Miocene rifting-depression transition stage, and the Pliocene to present depression stage. As the fault systems dominated the distribution of the paleo-highs and lows, it is critical to reconstruct the paleo-geomorphology and understand its impacts on sedimentation patterns in the Qiongdongnan Basin. The erosion amounts of the three key horizons were calculated by considering both the structural trend and thickness variation. The paleo-geomorphology maps were then constructed, indicating that the general structural framework of the Qiongdongnan Basin was generated in late Oligocene and was subsequently altered in Miocene. The characteristics and structural evolution of the fault systems may provide important hints for the petroleum exploration in the northern Qiongdongnan Basin.

Development of detachment fault system associated with a mature metamorphic more complex: insight from the Kaiping Sag, northern South China Sea rifted margin

Gengbiao LI[1]*, China University of Geosciences (1076500813@qq.com)
Qing YE[2], China University of Geosciences

Abstract

The Kaiping Sag, located in the northern South China Sea (SCS) rifted margin, characterized by the development of a mature and complete metamorphic core complex (MCC), which provides an excellent location to study the development of detachment fault system associated with MCC. In this study, a newly acquired high-resolution 3-D seismic reflection volume allows detailed analysis of the development of the KP detachment fault system. The master detachment fault displays a convex-upward shape, and the fault surface and its footwall at KP9 High suffered from denudation and flattening, generating the long-distance horizontal displacement by oblique sliding. Accompanying second-order faults include synthetic faults and antithetic faults, regularly distributed in the supra-detachment basin, at right angles to the prevailing extension direction. These faults are mainly developed in the syn-rift formations, predominantly up-steep and down-sloping medium-high angle normal faults. Comprehensively analyzing the activity pattern of the fault system and the characteristics of basin evolution, it can be assumed that the differential uplift of the mid-crustal ductile layer and the rolling-hinge activity of the MCC are the main reasons leading to the uniqueness of the detachment fault system. We propose that the KP MCC went through three stages from embryonic to mature: strong detachment stage, detachment-uplift composite stage, and strong uplift stage. During the transition, the controlled depositional faults were transformed from synthetic faults to antithetic faults, the Collapse Graben migrated to the front of the rolling hinge, new high-angle normal faults were developed centrally at the top of the uplift zone, and the old faults underwent different degrees of rotation. The developmental law of detachment fault system recognised in this study supplements and completes the existing rolling-hinge models, and provides clear and reliable practical examples to demonstrate the rationality of the model.

Geochemistry and petrogenesis of igneous rocks from the Yap forearc in the western Pacific: Implications for forearc magmatism

Ling CHEN[1]*, Second Institute of Oceanography, Ministry of Natural Resources, China (chenling@sio.org.cn)
Limei Tang[2], Second Institute of Oceanography, Ministry of Natural Resources
Jie Zhang[3], Second Institute of Oceanography, Ministry of Natural Resources

Abstract

Herein, we analyze the elemental composition and Sr–Nd–Pb isotopic data of the gabbroic rocks (gabbros and gabbroic diorites) from the forearc of the Yap trench in the western Pacific to investigate the early arc magmatism. The gabbroic diorites, which exhibit a negative Eu anomaly and relatively flat REE patterns with slight LREE depletion, represent the evolved magma that has undergone varying degrees of fractional crystallization. In contrast, the gabbros, which exhibit a positive Eu anomaly and a significant depletion of LREE, can be further classified into two groups. The noncumulate Group 1 gabbros have composition closely resembles that of gabbroic diorites and the Group 2 gabbros represents cumulate rocks formed through melt crystallization. Most of the studied gabbroic rocks exhibit negative anomalies in high-field-strength elements, such as Nb, Zr, Hf, and Ti, accompanied by very low Ti/V and Nb/Yb ratios. Based on these features, they are suggested to originate from the partial melting of a depleted forearc mantle, which is supported by their high 143Nd/144Nd ratios that are similar to those of forearc basalts (FAB). The forearc origin of gabbroic rocks is further supported by their plagioclase composition, which exhibits a higher anorthite content (An: 86–99) compared to the plagioclase in backarc and mid-ocean ridge gabbros when coexisting with identical clinopyroxene composition. However, even though the major- and trace-element compositions of the Yap gabbroic rocks are similar to those of FAB, their large-ion lithophile element content (e.g., Cs, Rb, Ba, and Th) and 87Sr/86Sr ratios considerably exceed the values of FABs, highlighting their similarity to boninites. In addition, their Ba/Yb and Th/Yb ratios are higher than the mid-ocean ridge basalt values and plot between the FAB and boninite fields in Ba/Yb versus Th/Yb diagram. Consequently, we propose that the Yap gabbroic rocks evolved from an early arc magma, which was produced by a combination of decompression melting and fluid-flux melting. Thus, they exhibit a transitional composition that falls between FABs and boninites. The exposure of intrusive rocks related to the early arc magmatism in the Yap forearc is a consequence of the extensive tectonic erosion induced by the collision of the Caroline ridge with the trench. This collision resulted in the erosion of the volcanic crust, exposing the underlying plutonic rocks. Therefore, intrusive rocks likely hold a preserved record of the early arc magmatism in subduction zones exhibiting extensive tectonic erosion. The Yap arc system is characterized by multiple episodes of magmatism, and the collision with the Caroline ridge may prevent the Yap arc magmas from evolving into mature arc magmas.

The Oceanic crustal structure and the magmatic accretion history of the South China Sea

chenghui ZENG[1]*, South China Sea Institute of Oceanology, CAS (chenghzeng@163.com)
zhen SUN[2], South China Sea Institute of Oceanology, CAS

Abstract

Plate separation is accommodated by magmatic accretion and tectonic extension, it is of great significance for studying the plate dynamics based on the ratio between them. The South China Sea (SCS) is typically representative of the slow-intermediate spreading marginal sea. However, there is a lack of holistic quantitative calculation of the magmatic accretion from the perspective of spatio-temporal distribution, which limits the cognition of the seafloor spreading process of the SCS.

We calculate the spatial distribution characteristics of M number, which marks the ratio of separation accommodated by magmatic accretion, in the SCS through seismic profiles. The main conclusions are:

(1) The M number of the SCS fluctuates in the range of 0.5~0.95. For each sub-basin, the M of the main spreading area of the northwest sub-basin (NWSB) of the SCS can reach above 0.9. In the east sub-basin (ESB), the M can be above 0.9 and a few areas can be as low as 0.7~0.8 in the early spreading stage (> 23.6 Ma). In the late spreading period (< 23.6 Ma), the values of M number vary alternately between 0.5~0.8 and 0.8~0.95 along the single seismic profile or along the single magnetic anomaly lineation in the ESB and the southwest sub-basin (SWSB).

(2) When the M number attain 0.93, small offset planar faults are developed in the oceanic crust, the horizontal displacement is less than ~0.5 km. When the M value decrease to 0.66, large offset low-angle faults are developed, the horizontal displacement can reach ~3 km. The dip angle of fault plane is less than ~30°.

(3) There is hardly any fault heave exceeding 5 km in all seismic profiles, implying that the magma supply cycles (less than 0.25-0.33 Myr) are shorter than large oceans. These calculations are consistent with the observation that very few oceanic core complexes are revealed.

Oceanic crustal structures and characteristics of Syn-Spread Magmatism in the Central basin of the South China Sea

Haixuan SUN[1]*, South China Sea Institute of Oceanology (2472223896@qq.com)
zhen SUN[2], South China Sea Institute of Oceanology

Abstract

The accretion process of the oceanic crust and the formed crustal structures are of great significance for understanding the dynamic mechanisms within the earth, the spreading history of ocean basins, and the interaction between magmatic and tectonic processes. Yet, the evolutionary characteristics of magmatic activity during the syn-spread period remain enigmatic due to the lack of seismically resolvable data and dredged rock samples in the central basin of the South China Sea. In this study, we present two maps of crustal thickness and sediment base depth to reveal the fluctuation of magma supply during seafloor spreading. First, we integrate publicly available seismic data with previously obtained gravity results to create an enhanced crustal thickness map. Then, the improved bathymetry and sediment thickness grids are constructed and the sediment base depth in SCS is mapped as constrained by seismic data. The results find, that the crust is thickened north of the extinct spreading center (ESC) and mostly located in the middle part of the central basin, corresponding to ages of ~29–15 Ma, while a much narrower region of thickened crust is visible for the corresponding southern part. Moreover, the width of the thickened crust region reflects a prominent increasing to decreasing change from north to ESC with the peak around the fossil ridge. Meanwhile, the sediment base uplifts in an irregular broad band of half-width ~120 km north of the ESC, mostly located between ESC and fossil ridge. The combination of these maps indicates that the magma budget firstly increases and then decreases towards the ESC, reaching the peak around the fossil ridge and the through around the ESC. The results provide insights into the dynamics of mid-ocean ridge spreading and associated crustal accretion processes. Furthermore, the implications of these findings extend to a broader understanding of oceanic crustal evolution, magmatic processes, and resource potential in the South China Sea.

Abstract

The Central Indian Ocean Basin (CIOB) encompasses several enigmatic tectonic features, such as the Comorin Ridge, whose origin and development remain largely obscure. These tectonic features play a major role in elucidating the genesis and evolution of the CIOB, which is closely linked to the early-mid Cretaceous Antarctica-India rifting and dispersal, followed by the late Cretaceous India-Madagascar break-up. The northward voyage of the Indian plate and its adjoining margins was accompanied by frequent interactions between concurrent mantle plumes and spreading centers. Despite its profound geodynamic significance, a comprehensive understanding of the CIOB and its adjoining regions has remained elusive due to the scarcity of deep-penetrating, high-quality seismic refraction and reflection data. A thorough comprehension of the crustal processes that have shaped this region necessitates velocity and structural information of the crust and upper mantle obtained through deep-penetrating seismic observations.

In this study, a ~420-km long wide-angle reflection and refraction seismic profile in the CIOB south of Sri Lanka is utilized to enhance our understanding of the geodynamic evolution in the area. Two-dimensional seismic travel-time tomographic inversions reveal the presence of an anomalously thick crust (~14 km) beneath the Comorin Ridge, gradually thinning out towards the east, towards the center of the geoidal low. It is observed that the crust in the east of the profile appears to be of a normal oceanic type. We attribute the lateral diversity in crustal type to possible magmatic underplating beneath the Comorin Ridge. It is interpreted that concurrent plume-ridge interaction during the late Cretaceous India-Madagascar break-up may have caused this crustal underplating. These findings hold significant implications for a better understanding of plume-ridge interaction processes along various passive margins, as well as for the precise reconstruction of India-Madagascar dispersal.

New insights to slab interface and crustal structure in Sumatra subduction zone: constraints from novel receiver function analyses

Ling CHEN[1]*, State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences (lchen@mail.iggcas.ac.cn)
Mingye Feng[2], State Key Laboratory of Lithospheric Evolution, Institute of Geology and Geophysics, Chinese Academy of Sciences

Abstract

The Sumatra subduction zone, where the Australian plate is subducting obliquely beneath the Sunda plate, hosts the most devastating earthquake (2004 Mw9.2 event) in this century and strongest volcanic eruption (Toba eruption at 74 ka) in Quaternary, and thus has become a focus of subduction zone studies. To better understand the subduction dynamics and related geological phenomena in this region, recently we conducted detailed seismic studies based on teleseismic receiver function (RF) analysis. We first focus on the geometry and structure of the subducting plate boundary to understand slab deformation and slab-mantle wedge interaction in Sumatra. By developing a Dip Direction Searching (DDS) method of station-based RFs, we constrained the geometries of the top and bottom interfaces of a dipping Low Velocity Layer (LVL) around the subducting plate boundary beneath the forearc area of Sumatra. The LVL bottom interface, interpreted as the subducting oceanic Moho, shows lateral variations in its dip direction, indicating an along-strike bending of the slab that probably is related to the oblique oceanic subduction and could trigger large earthquakes. The top and bottom interfaces of the dipping LVL are found locally nonparallel (with a deviation up to 23˚), and the LVL appears to thicken with depth and apparently thicker than a normal oceanic crust (10-14 km versus 6-7 km). These features suggest that the LVL is composed of not only the subducting oceanic crust, but probably also a layer of slab-dehydration induced low velocity serpentinized mantle on its top, forming a diffuse plate boundary along the Sumatra subduction zone. We then investigated the crustal structure at the volcanic arc area of Aceh in northern Sumatra, to understand crustal deformation and its relationship with arc volcanism. We expanded the commonly used RF H-κ stacking to RF H-Φ stacking scheme for dense nodal array data and estimated the crustal thicknesses and melt fractions of the area. Our results show an overall thin crust (~29 km on average) with high Vp/Vs ratios (~1.98) and melt fractions (~12% on average). The crustal melt fraction increases as the crustal thickness decreases northwestward, reaching the highest value of 19% and the thinnest crust of 22 km at the northwestern edge of Sumatra. The melt fractions estimated for Aceh are comparable to other active volcanic areas in the world, and the observed melt fraction-crustal thickness correlation corroborates previous speculation that high crustal stretching associated with

the opening of the Andaman Sea facilitates melt intrusion into the crust and northward Quaternary volcanic migration in Aceh. This suggests that the arc volcanism in Sumatra may not be controlled merely by the oblique subduction process, but is possibly also modulated by continental tectonics over a broader region. To further understand the interactions and coupling between the oblique oceanic subduction and overlying continental tectonics in Sumatra requires improved constraints on the structures of various depths and scales from multidisciplinary observations.

Constraining water flux in the Manila subduction zone with seismic data

Zhenteng WANG[1]*, South China Sea Institute of Oceanology, Chinese Academy of Sciences (wangzhenteng234@163.com)
zhen SUN[2], South China Sea Institute of Oceanology, Chinese Academy of Sciences

Abstract

Subduction zone is the major location for water on earth recycled into the deep interior of Earth, it's also the location of large submarine catastrophes such as earthquake and volcanic eruption. Numerous studies have shown that there is a positive relationship between the medium-depth earthquakes and the larger subduction water fluxes, while hydration plays an important role in subducted water fluxes. The Manila Trench is located between the South China Sea and the Western Philippine Sea, along which a narrow portion of the southern section of the Manila Trench concentrates more than 80% of the medium- and deep-source earthquakes along the entire trench, above which the notorious super large Pinatubo volcano locates. In order to decode the relationship between subducted water fluxes and catastrophic volcano eruption, we plan to calculate the variation and its controlling factors of water flux along trench first. Here we use dozens of multichannel seismic (MCS) reflection and wide-angle seismic data spanning the Manila subduction zone from south to north to establish the relationship between uplift faulting and hydration at the outer edge of the trench. We quantify the amount of South China Sea pore and structurally bound water entering the Manila subduction zone by comparing it with other subduction zones that are relatively well-studied around the world. Finally, we attempt to establish a link between the water subduction fluxes at the trench and seismic hazards and catastrophic volcanic eruptions (e.g., Mt. Pinatubo), with the ultimate goal of providing theoretical support for disaster monitoring and prediction in volcanic and seismic hazard-prone island nations.

Seismic and Gravity Data Analysis of Oceanic Core Complexes in the West Philippine Basin

Jingyan Zhao[1], Second Institute of Oceanography
Yanghui Zhao[2]*, Second Institute of Oceanography (zhaoyh@sio.org.cn)

Abstract

Detachment faulting related to oceanic core complexes (OCCs) has been suggested to be a manifestation of slow seafloor spreading. Although numerical models suggest OCCs form under low magma supply, the specific interaction between magmatism and tectonic faulting remains elusive. Recently acquired seismic profiles from the spreading center of the West Philippine Basin, complemented by satellite gravity data, have shed light on the sequential emergence of distinct OCC structures along the strike of this mid-ocean ridge. The combination of geological interpretation of the seismic profiles and the inversion of gravity data has yielded the following foundlings. We identified a magma-rich spreading phase at 36 Ma, indicated by a magmatic top basement and normal oceanic crust with shallow-penetrating high-angle faults. An axial valley reveals an along-strike transition from normal to highly tectonized oceanic crust over a distance of 70 km. Two older OCCs with concave-down fault geometries and a younger OCC with steep-dipping faulting suggest sequential detachments with the same polarity. Our findings suggest: (1) slow seafloor spreading is cyclical, alternating between high-angle faulting with a relatively high magma supply and detachment faulting with limited magma supply; (2) sequential development of younger detachments in the footwall of its predecessor leads to an asymmetric split in the newly accreted crust; and (3) the life cycle of OCC ends with high-angle faults that overprint the detachment and act as magma pathways, sealing the OCC. Our study captures the dynamic interaction between high-angle and detachment faults and their concurrent and subsequent relationship to magmatic systems. This reveals that strain distribution along strike is critical to OCC formation, thus enriching our understanding beyond conventional considerations such as spreading rates and melt budgets at mid-ocean ridges.

Rift architecture and evolution controlled by an exhuming and decapitating metamorphic core complex in the Kaiping Sag, northern South China Sea margin

WenDi LI[1]*, China University of Geosciences (lwd15184488553@163.com)
Qing Ye[2], China University of Geosciences

Abstract

The architecture and evolution of rift basins overlying a metamorphic core complexes (MCCs) have not yet been well reported. The northern margin of the South China Sea was the main rift period of sedimentary basins from the Late Cretaceous to the Middle Oligocene, undergoing five important tectonic movements. The basin structure was complex, and the metamorphic core complex developed and evolved during the Middle to Late Eocene significantly affected the basin structure. In this study, using high-quality 3-D seismic reflection data we study how the Cenozoic rifting structure and evolution of the KaipingSag relate to the development of an underlying metamorphic core complex, the Kaiping metamorphic core complex, in the northern South China Sea margin.

The Kaiping sag was a half-graben structure in the early stage of deposition (49Ma~43Ma). With the development and uplift of the metamorphic core complex, the original medium-high angle section bends, forms a sinusoidal shape. The sedimentary basin was strongly extended, the depth of the depocenter increased, and the top of the core complex was gradually exposed to the water surface for erosion(43Ma~39Ma). The development of metamorphic core complexes is thought to favor sediment accumulation.

The Kaiping sag suffered significant denudation, forming a large-scale stratigraphic angular unconformity inside the sag. In the Kaiping Sag, the strata deposited before the activity of the metamorphic core complex underwent significant rotation as the metamorphic core complex developed and uplifted. Evidence shows that the two areas subject to the strongest denudation in the KP Sag are the highest uplift points of the core complex. Current research shows that the impact of the metamorphic core complex on the structure of the basin overlying it is huge and complex. The reconstruction of the structure and evolution of metamorphic core complexes and the rift basins above them is crucial for evaluating and predicting the oil and gas accumulation patterns of metamorphic core complex type basins.

New data on the age of the basement of the Devonian Magnitogorsk island arc (the Southern Urals) according to the results of U-Pb LA-ICP-MS dating of zircons from tuffs of the Irendyk Formation

Ivan SOBOLEV[1]*, IGEM RAS (sobolev_id@mail.ru)

Abstract

Zircons from boninite tuffs (sample S1-16; 54°37'19.7"N, 59°43'32.2"E) belonging to the Lower-Middle Devonian (Emsian–Eifelian stages) Irendyk Formation (Zhdanov et al., 2018) were studied for the first time in the Western Magnitogorsk Zone of the Southern Urals, 1 km southeast of the Polyakovka village. Boninite tuffs are massive in thin sections, but demonstrate clear graded bedding in outcrops. The rocks are medium-grained and composed of porphyry amygdaloidal and massive basaltic andesite fragments and clinopyroxene crystalloclasts. For the first time, we determined the U-Pb (LA-ICP-MS) age of zircons from boninite tuffs. Most of zircon grains are rounded to varying degrees, and some of them are euhedral. According to CL images, zircons without zoning dominate in the sample, grains with oscillatory zoning are less common. The Th/U ratio for all grains >0.1, which is typical for zircons of magmatic origin. A total of 108 individual zircon grains were analyzed. The results for 31 grains were excluded from consideration due to high discordance (the criterion for rejection of analyses is –10>D>10). For the remaining 77 zircons, a wide age range was obtained from 236 to 3587 Ma. No age comparable to the time of deposition of the rocks of the Irendyk Formation (Zhdanov et al., 2018) was obtained for any of the zircons. There are five grains (6.5% of the total sample) of the Middle-Late Triassic, Permian and Carboniferous (Serpukhov-Gzhel) age (236–325 Ma), which may be the result of isotopic rejuvenation under the influence of superimposed processes associated with Late Paleozoic accretion-collision events in the Urals. Five zircon grains (6.5%) have Silurian-Cambrian ages – 428-534 Ma. Precambrian ages were obtained for 67 grains, among which Neoproterozoic zircons predominate (35% – 27 grains, 559–997 Ma). Zircons of Mesoproterozoic (14% – 11 grains, 1004–1564 Ma), Paleoproterozoic (23% – 18 grains, 1649–2498 Ma) and Neoarchean (12% – 9 grains, 2501–2800 Ma) age are less common. The two oldest grains (3%) have Meso- and Paleoarchean ages – 3179 and 3587 Ma.

The results of dating of zircons from boninite tuffs demonstrate a significant predominance of Precambrian xenogenic zircons over Paleozoic ones, which may indicate the presence of an ancient Precambrian basement at the base of the Magnitogorsk Devonian island arc. Similar results were previously obtained for the Paleozoic island-arc of the Polar Urals (Sobolev et al., 2017).

Abstract

The thermal history of margins controls the development of hydrothermal systems during rifting, diagenetic processes in the sediments and the generation and preservation of hydrocarbons. It also affects the depth of the oceanic gateways formed during continental break-up, thereby influencing ocean circulation and ultimately climate (Brune et al., 2023, Pérez-Gussinyé et al., 2023, Peron-Pinvidic et al., 2019). However, observed heat-flow values however, do not always comply with classic rifting models. Here, we use 2D numerical models to investigate the relationship between rifting, sedimentation and thermal history of margins. We find that during the synrift, the basement heat flow and temperature are not only controlled by extension factor, but also by synrift sediment thickness and the evolution of deformation. As this progressively focuses oceanward, the proximal sectors thermally relax, while the distal sectors experience peak temperatures. This time lag is important for wide rifted margins. In the postrift, the lithosphere under the hyperextended margins does not return to its original state, at least for ~100 Myrs after breakup. Instead, it mimics that of the adjacent oceanic plate, which is thinner than that of the original continental plate. This results in heat flow values increasing oceanward at postrift stages where classic rifting theory predicts complete thermal relaxation. Our increased heat-flow estimations, may extend hydrocarbon plays into distal margin sectors and adjacent oceanic crust, previously discarded as immature. Finally, our models indicate that commonly used temperature approximations in basin analysis may strongly differ from those occurring in nature (Pérez-Gussinyé et al., 2024).

Abstract

Orogenic sutures are crustal/lithospheric-scale lineaments that mark the limits between terranes previously separated by tectonic plates active margins. In the SE Brazilian continental margin, a Cambrian NE-SW suture zone is marked by an expressive magnetic anomaly onshore that extends offshore to the proximal Santos basin (Rio de Janeiro). The suture is product of the last Gondwana amalgamation event, being represented by a high positive curvilinear lineament, by which the magnetic gradient decreases to NW after pass it. This lineament separates two contrasting geological terranes: a Neoproterozoic magmatic domain (Oriental Terrane - ORT), to the west, and a Paleoproterozoic gneissic terrane, to the east (Cabo Frio Tectonic Domain - CFTD). The dip direction of this suture and the vergence of the subduction that generated it is still motive of debate by researchers. The studied area comprises mainly two geological units separated by a thrust fault (suture zone): dioritic to granitic Paleoproterozoic rocks with metabasite layers (Região dos Lagos Complex, from CFTD) and Ediacaran aluminous paragneisses with calcsilicate layers (Palmital Succession, from ORT). Magnetically, the Paleoproterozoic gneisses are associated with high amplitude, long wavelength (55 km) and numerous magnetic rectilinear and curvilinear lineaments. Amplitude ranges between -100 and 452 nT, mostly higher than 150 nT. Otherwise, the Palmital paragneisses coincides with low frequencies, a long wavelength (55 km) magnetic domain and amplitudes <0 nT, resulting in a lateral contrast of more than 500 nT with Região dos Lagos Complex. The focus of the present work is to determine how this suture extends on depth and the source of the magnetic anomaly for, consequently, understand the nature of the basement that constitutes the continental margin, once the suture extends offshore to SW. For this, we built an unprecedented magnetic susceptibility database including values obtained both on field and laboratory. Based on this database, and also on standard remanence and density values, we modeled two magnetic sections made on field along the suture zone on GMSYS. We try to variate only susceptibility values. So, geophysical data was integrated with geological maps in order to build correlations so that petrological characteristics and fluids interaction during orogenic events was considered during modeling parameters adjustment. Finally, models have a better fit with the suture dipping to NW, suggesting a west vergence subduction. Also, Cabo Frio Tectonic domain is the probable source of the magnetic anomaly. The methodology and database developed in this work allows further researches modelling, including in areas were the geological information is unknown.

Intrusive mantle flow induced by thermal heterogeneity during rift propagation

Min-seok JANG[1]*, Kangwon national university (alstjr2264@kangwon.ac.kr)
Byung-dal So[2], Kangwon national university
jimin Kim[3], Kangwon national university

Abstract

Extensional forces induced by the plumes or relative motion of plates cause rifting to separate continents and form new oceanic crusts. In addition, the mantle uplifted by rifting is known to have an essential influence on lithospheric evolution through igneous activity such as magmatic underplating and LIP(Large igneous province). Recent studies from seismic wave surveys in the EARS(East African Rift System) suggest that mantle flow may also parallel the ridge. Although previous studies have shown that uplifted mantle can flow long distances from a ridge in an extensional direction, an understanding of flow in parallel directions is still not well defined. In particular, the flow of the lower mantle and its interaction with the lithosphere during rift propagation requires further investigation. We used the thermo-mechanical geodynamics code ASPECT to model rift propagation and trace lower mantle convection. Mantle flow in different lithospheric environments has also been evaluated by varying the initial and boundary temperature conditions, which is an important factor of viscosity. The model results confirm the generation of a mantle flow parallel to the ocean ridge. The mantle flow becomes more active and vigorous at higher temperatures condition in the rift zone, extending several hundred kilometers in the hottest models. Mantle intruded beyond the rift tip into the bottom of the lithosphere, and convection persisted after rift termination. These results suggest that rift propagation processes in high-temperature environments can invade the lower mantle outside the rift zone. We propose that the sub-lithospheric intrusion of the hot mantle by rift propagation has the potential to generate intraplate volcanism or magmatic underplating.

Earthquake rupture features in near-surface regions, Korea

Youngbeom CHEON[1]*, Active Tectonics Research Center, Korea Institute of Geoscience and Mineral Resources (cheonyb@kigam.re.kr)
Chang-Min Kim[2], Department of Geology, Division of Geology and Geophysics, Kangwon National University
Jin-Hyuck Choi[3], Active Tectonics Research Center, Korea Institute of Geoscience and Mineral Resources

Abstract

We present the structural characteristics of earthquake ruptures, which propagate and terminate at and near the ground surface, based on multi-scale observations of the paleoearthquake records distributed throughout South Korea. Paleoearthquake ruptures are mostly observed along the NNE–SSW-striking and WNW–ESE-striking pre-existing faults, which are the most dominant sets of inherited structures in Korea. Especially, some of them occurred along the boundary between the inherited fault core and damage zone. The NNE–SSW-striking and WNW–ESE-striking ruptures primarily show different movement senses; dextral and sinistral slips with small reverse components (i.e., dextral and sinistral transpressional kinematics), respectively, due to the imposed neotectonic stress (ENE–WSW maximum horizontal stress). The ruptures propagated upwards to the shallow subsurface along the <3-cm-wide specific slip zone. However, within unconsolidated sedimentary strata (below the surface), the numerous ruptures change their natures as follows. (1) The ruptures tend to branch into several narrower splays (less than a few millimeters wide). The branched splays can be grouped into those breaking ground surface and those terminating below the surface. (2) In the case of ruptures terminating in shallow subsurface, the dip angles of these branched ruptures decrease upward and their strikes change from NNE–SSW to NNW–SSE and from WNW–ESE to NNW–SSE, respectively. (3) The NNW–SSE-striking fault splays with a lower dip angle show much greater rake angles of striations, indicating reverse-dominant kinematics, unlikely the mostly strike-slip sense on high-angle fault splays in the basement rocks. (4) The deformation mechanism of the slip zone is predominantly characterized by a granular flow (i.e., rearrangement of clasts rather than fragmentation and truncation of them). Our findings suggest that the near-surface features of earthquakes in Korea are controlled by the following factors. (1) The inherited fault geometry that is unfavorable with respect to the imposed stress (ENE–WSW maximum horizontal stress) at basement depths in terms of reactivation on the fault, and lack of upward extension of the inherited fault to the shallow surface (or recent unconsolidated sediment). (2) The ratio of vertical (overburden) stress to minimum horizontal stress, which changes from deep to shallow levels (i.e., at depth of ~200 m). (3) Physical properties of unconsolidated sediments, which have low inter-granular cohesion that favors granular flow and distributed deformation.

Abstract

While many faults are locked and capable of hosting earthquakes, some other faults creep, silently accommodating tectonic loading through slow, gradual slip. Currently, the slip behavior of faults is thought to be explained by the frictional properties of the rocks forming the fault material; yet studies suggest that the relationship between rheology and slip behavior may not be as straightforward. Here, we introduce a novel interpretation of fault creep, proposing that the geometrical complexity of fault networks primarily controls fault slip behavior. We investigate the link between fault network geometry and surface creep rates in California and observe that regions with aligned fault network geometries are prone to hosting aseismic slip while more complex regions tend to be locked. Other creeping fault systems, such as the North Anatolian Fault and the Chaman Fault, also demonstrate similar correlations, suggesting that the influence of fault network geometry on fault creep may be a universal behavior. Through correlation studies of key physical variables including subsurface shear wave velocity, surface heat flow, and fault nonplanarity, we conclude that other parameters are not significant in explaining either fault creep or fault misalignment, indicating fault misalignment as a predominant and independent factor for explaining fault creep. This finding challenges traditional notions that earthquake stability is primarily governed by rate-and-state dependent frictional properties on single fault strands, and raises many questions about how to best understand the fundamental nature of earthquakes.

On the active faults around Gyeongju, Korea: a possible relationship with the 779 AD Gyeongju Earthquake and the Buddhist temples/pagodas in the Silla Dynasty (57 BC – 935 AD) as a 'Bibo Pungsu (Feng Shui theory)'

Chung-Ryul RYOO[1]*, Korea Institute of Geoscience and Mineral Resources (ryoocr@kigam.re.kr)
Taehyung KIM[2], Korea Institute of Geoscience and Mineral Resources

Abstract

In Korea, we have many historic monuments around Gyeongju, the capital city during about one thousand years long of the Silla dynasty (57 BC – 935 AD), especially many Buddhist temples and pagodas. By historical seismic records from 2 AD to 1904, there are several strong earthquakes occurred around Gyeongju, Korea. The 779 AD Gyeongju Earthquake is reported as the most disastrous earthquake in the Korean history about 100 peoples died. The 779 AD Gyeongju Earthquake is estimated as M 6.5-7.0, and is considered as strong enough to make a surface rupture around Gyeongju. Gyeongju is located in a junction area of two important faults, the Yangsan and the Ulsan faults. Several active faults are found in these fault zones around Gyeongju during last 30 years. We discovered that there are the Buddhist temples and pagodas near some active faults along the Ulsan Fault Zone. In the Korean history many temples and pagodas are reported to built mainly after 780 AD, which support a possible relationship between the 779 Gyeongju Earthquake with possible surface ruptures and the Buddhist temples with pagodas in the Silla Dynasty as a 'Bibo Pungsu (Feng Shui theory)'. The Silla peoples believed that the temples and pagodas could be control and calm the underground dragons making the big earthquakes. We suggest that some temples and pagodas are historically beautiful and tectonically useful to trace a possible surface rupture occurred during 779 Gyeongju Earthquake.

Abstract

In the structural divisions of Taiwan, the coastal plain of Miaoli belongs to the Outer Foothill of the Western Foothill. Approximately six million years ago, the Penglai Orogeny began, leading to significant tectonic activities in the Miaoli region, resulting in numerous faults and folds. These structures have concurrently influenced the occurrence and preservation of fossil echinoids in the region. Goal of this study is study and document the deformed and fractured specimens of the fossil sand dollar Scaphechinus mirabilis from the Xiangshan Member of the Toukoshan Formation in Miaoli County, Taiwan.

Unlike deformed fossils that are commonly reported from the Mesozoic and older strata, new examples of deformed fossils are recovered from the Pleistocene strata in Taiwan. Micro-CT tomographic imaging and rendering of deformed sand dollars reveals 3D geometry of fault planes in hand sample size. Under the thin sections, additional tectonic structures, such as pressure solutions, box folds and monoclines, are evident. While some ductile and brittle deformations, such as fractures along the taphonomically weak ossicle boundaries, may have sedimentary origin(s), fault features that were triggered by earthquakes are undoubtedly preserved in rare specimens. This study provides new and unique evidence to reveal key missing information to understand better the neotectonics for the collision between the Philippine Sea Plate and Eurasia Plate in Taiwan based on fossils.

Abstract

Unlike interplate, where earthquakes are periodic and frequent, predicting earthquakes in the intraplate, where they occur randomly, is challenging. Furthermore, the difficulties are compounded in regions where slow deformation and complex fault internal structures. The Korean peninsula is a prime example of a region that fits all of these cases. We used multiple methods to identify characteristics of Quaternary surface rupture and obtain paleoseismic information on the central Yangsan Fault, one of the most major tectonic lines in Korea. Topographic analysis using a high-resolution LiDAR image revealed the 2-4 m fault scarp and the 50-150 m dextral offset deflected stream, which led to the recognition of a 7.6 km lineament. Electrical resistivity surveys were conducted on 25 lines along the lineament, and low resistivity anomalies suggestive of faults were observed along most of the lines. In 5 trench surveys, N-S to NNE-striking faults cut Quaternary sediments, and OSL, IRSL, ESR, and 10Be dating were performed on the sediments. Taken together, all of our results show that the most recent earthquake in the study area was 3,000 years ago, with at least three faulting events. The displacement per event is 0.33-2.81 m, the cumulative displacement is 3.1-94 m, and the estimated maximum magnitude is 6.7-7.2. The average slip rate is 0.14 mm/yr, and the recurrence interval is estimated to exceed 10,000 years according to the quasi-periodic model. The central Yangsan fault has been continuously reactivating since the Quaternary as a dextral strike-slip with a small reverse component, with a top-to-west geometry of the pre-existing fault core under ENE-WNW compression. Our results not only provide fundamental elements for seismic hazard assessment but also contribute to the understanding of intraplate seismicity.

Mingxing Gao[7], Xinjiang University, Urumqi, China

Abstract

The understanding of the spatial-temporal distribution of past earthquakes is essential to assess the event recurrence behavior and to estimate the size of potential earthquakes along major strike-slip fault systems. However, the scarcity of paleoseismic data remains a major hurdle in this endeavour. We document a paleoseismic record over the last 8kyr along the central-eastern Altyn Tagh Fault (ATF). First, we identify six very likely large earthquakes that potentially ruptured the Aksay section of the ATF. Employing a Bayesian model approach, we present modeled range ages of 6339 – 5220 BC, 5296 – 4563 BC, 3026 – 2677 BC, 1324 – 808 BC, 314 – 632 AD, and 916 – 1236 AD. The mean recurrence time is 1371±625 yr with a COV of ~0.46, suggesting a quasi-periodic behavior. In the same fault section, 90 horizontal offsets record an average coseismic slip of 5.1 1.4 m for the most recent event (MRE) and suggest at least four older earthquakes plausibly with a similar slip distribution.

We find that at the local scale (fault section) the earthquake recurrence is quasi-periodic along the ATF. However, at the regional scale (fault system) the tectonic strain seems to be released in bursts of seismic activity punctuated by periods of relative quiescence. Applying site-to-site correlation of rupture ages along four fault sections of the central-eastern ATF, we found that ten large earthquakes occurred in clusters during the middle (5.4 – 4.4 kyr) and late (1.6 kyr - present) Holocene. These bursty periods of seismic activity show mean interevent times of 495 ± 129 yr and are preceded by millennial long-lull periods of 1360 ± 223 yr. Based on this temporal organization we suggest that the central-eastern ATF is either at the early stage of a seismic quiescence period, or it might currently be in the late stage of an earthquake cluster. In such a scenario, given the 390-yr elapsed time since the MRE there exists a possibility of a forthcoming large earthquake occurring within the next century.

Shu-Huei Hung[4], Department of Geosciences, National Taiwan University, Taiwan

Abstract

Fault zone head waves (FZHWs) offer insights into fault structures at seismogenic depths. We investigate the northern segment of the Longitudinal Valley (LV) fault system, a major suture zone between the Eurasian Plate and the Philippine Sea Plate. The analysis focuses on 22 stations within a 60 km by 28 km area along the fault, using ~8000 small-to-moderate earthquake seismograms recorded from 2012 to 2018. Employing Ross and Ben-Zion's algorithms, we detect 272 robust head waves from 149 events, primarily along the west-dipping Central Range fault, indicating a consistent velocity contrast across this segment. Validation of automatic FZHW picks confirms accuracy through particle motion, polarization, and moveout analyses despite complexities in subsurface structures and topographical changes. Our investigation reveals a constant moveout pattern from P wave to FZHW time differences, indicating a shallow bimaterial interface significantly impacting the wavefield near or beneath stations. We further fit the moveout and constant arrivals with two models to the differential P and head wave arrival times to explore possible local variations of the constant trend. The Akaike Information Criterion applied to the constant and classical moveout pattern suggests spatially complex significant results that, together with the depth distribution of the involved events, indicate a deeper-reaching bimaterial interface. This analysis yields an average velocity contrast of approximately one per cent, aligning with previous FZHW studies along major plate boundary faults. Overall, this study enhances understanding of fault structures in the LV fault system and underscores the importance of FZHWs in providing high-resolution fault information.

Abstract

On September 17, 2022, a magnitude 6.6 earthquake occurred, followed by a magnitude 6.8 mainshock in Chihshang approximately 17 hours later, along the southern Longitudinal Valley in eastern Taiwan, where the Eurasian and Philippine Sea plates meet. This seismic event caused significant damage to buildings and the surface. In order to investigate the gas-bearing properties of the Chihshang Fault (CSF) zone and gain a better understanding of the degassing behavior, soil gas surveys were conducted to examine gas species and CO2 degassing. Our findings indicate that the observed increase in CO2 flux at the surface after the CS earthquake could be attributed to the release of gases from both deep and shallow sources, with the enhanced permeability of the fault system playing a role in this process. The presence of a heavier 13C isotopic composition provides evidence of an additional contribution of CO2 gas migrating from depth to the surface, a phenomenon that persisted for at least three months after the earthquake. These observations suggest that the CSF system acts as a conduit connecting deep and surface gas reservoirs, with CO2 emissions linked to significant seismic activity. The earthquake-induced microfractures may gradually heal and return to their original state. Based on our estimates, the total natural CO2 degassing around the entire CSF zone is approximately 1200 t/d before the Chihshang earthquake and 2200 t/d after the earthquake. These findings shed light on the dynamic behavior of gas emissions associated with seismic events and provide valuable insights into the degassing processes within the study area.

Frictional slips on artificial fault planes implicating periodic earthquakes along active tectonic plate boundaries

Insun SONG[1]*, Korea Institute of Geoscience and Mineral Resources (isong@kigam.re.kr)
Yu Na LEE[2], Kongju National University

Abstract

Frictional slips along subduction plate boundaries are often observed as an alternative behavior between interseismic locking and coseismic rupture. The unstable slips known as stick-slip failure occur along the seismogenic zone of a convergent boundary. The seismogenic portion does not extend all the way to the trench, and the aseismic boundary is called the updip zone. We have conducted a series of double direct shear tests on saw-cut planes with three blocks of Hwangdung granite to simulate the frictional slip on the convergent boundary with increasing depths. We prepared a double direct shear apparatus with three rock blocks in parallel, where the middle one slipped against the outer blocks. The shear apparatus was placed in a pressure cell for applying the normal stress on the 3 x 4 cm contact planes with the confining fluid pressure. The planes were subjected to shear stresses by moving the middle block against the outer ones using a loading frame with a jack. For the test, we first applied the normal stress on the artificial fault planes with the confining fluid pressure and kept the pressure constant using a syringe pump. Then we pushed up the pressure cell against the loading frame bar with the jack that was actuated by fluid pressure from a syringe pump controlled with constant flow rate. Thus there exists some spring compliance between shear planes and syringe pump that we actually controlled. This experimental system was designed to imitate the convergence of tectonic boundaries where the control of plate movement takes place far from the fault planes. Our experimental result revealed that the stick-slip behavior occurred at high normal stress on the planes but clearly disappeared at low normal pressure (lower than 3 MPa replicating shallow depth). The pressure drop at coseismic slip proportionally increases with the normal stress (or depth). These results are consistent with the observation of frictional slip behaviors along subduction plate boundaries showing aseismic zone at very shallow depth and periodic coseismic ruptures accompanying with earthquakes.

Abstract

The East Solsona Basin Fault (ESBF) forms part of the northern segments (collectively named West Ilocos Fault System) of the Philippine Fault Zone (PFZ) on Luzon Island. The West Ilocos Fault System (WIFS) consists of a network of strike-slip, reverse, and normal fault segments, whose major strands have generated strong to major earthquakes in recent years, notably the Mw7.7 1990 Luzon Earthquake and the Mw7.0 2022 Northwestern Luzon Earthquake. Despite its active seismicity, several segments of the WIFS such as the ESBF remain understudied. In this study, we examine geomorphological, geophysical, and paleoseismological data to establish the rupture history and hazard potential of the fault. Offset streams, truncated spurs, and subtle elevation changes were interpreted from anaglyph images and high-resolution digital topography data. Geomorphic markers indicate a general sinistral movement of the fault, with the fault scarp trending N20-35°E and dipping northwest. Ground penetrating radar surveys conducted along and across the fault scarp reveal discontinuous reflectors, corresponding to fault strands at a depth of about 5 m. Paleoseismic trenching conducted at one site reveals at least ten (10) stratigraphic units and four (4) fault strands, with minor vertical offsets ranging from 10 to 30 cm. Radiocarbon dating of organic sediments infers that at least two surface-rupturing earthquakes occurred along this fault segment over the past 1200 years, establishing recent movement along the ESBF.

Neotectonic deformation and long-term behavior of Masjed-e Soleyman Dam, Iran

Arash Barjasteh[1]*, Khuzestan Water & Power Authority (KWPA) (barjasteh@hotmail.com)

Abstract

Fault movement in dam foundation and reservoir is one of the seismic hazards that can lead to extensive structural damage in the dam and appurtenant structures. In this article, neotectonics deformation in the area of Masjed-e Soleyman dam in Khuzestan province is investigated considering its location in the most active seismotectonic zone of Iran. The dam height is 177 m with an annual 3,700 million kilowatts per hour of hydroelectric power energy. The construction of the dam was completed in 2001 over the Karun River. The foundation rock of the dam is composed of Agha-Jari Formation sandstones besides conglomerates of its member called Lahbari Member. The studied area is located in the northern part of Dezful Embayment in the folded Zagros, and deformation of the Neogene Formations exposed in the studied area is related to the activity of the surrounding faults, especially the Lahbari and Andeka faults. NW-SE trending Lahbari fault with thrust mechanism is the most important fault in the region that lies in the southwest of the dam. The Andeka fault passes through the north of the right abutment of the dam while changing its strike from northwest-southeast to east-west near the dam site. The change in the trend of the fault is associated with a change in its mechanism from strike-slip in the northern sector to thrust in the southern sector. Additionally, morphotectonic features of the dam site region indicates existence of a NE-SW lineament with a left-lateral displacement upstream the dam axis. The neotectonic movements such as faulting in post-Miocene Formations, tilting in the river course, extensive rock falls and fault scarps are visible in the dam vicinity. The location of the dam between the two mentioned active faults caused heterogeneous compression, disturbed bedding and tight synclinal structure at the dam site. Dam monitoring data confirms progressive deformation of the present formations in the investigated area. The aim of this article is to explain and discuss the possible relationship between the geological setting and the observed problems.

Multi-disciplinary active fault mapping in the central Gyeongju, SE Kore

Jinhyun Lee[1]*, PUKYONG NATIONAL UNIVERSITY (Jinhyunlee747@gmail.com)
Young-Seog Kim[2], PUKYONG NATIONAL UNIVERSITY

Abstract

Active fault mapping is crucial for earthquake mitigation, particularly in regions with highly anthropogenic modifications and low slip rates. Records of paleo surface ruptures can be traced using multi-disciplinary methods. In the Gyeongju area of SE Korea, we utilized LiDAR/aerial photography, trench, and geophysical data to classify the faults into the Cheongun (C), Wangsan (W), Sinpyeong (S) and Galgok (G) segments. These segments are located in the merging area of the Yangsan-Ulsan fault system and exhibit a north-south trend. All four segments display reverse fault characteristics, with variations in fault movement depending on the fault geometry. Through multi-disciplinary active fault mapping, the precise distribution of four segments was identified, with deformations in the Miocene strata serving as key evidence. The segments deformed Miocene sedimentary layers and cut through Holocene alluvial/fluvial deposits. The C-S-G segments are structurally developed as step segments, and the W segment is isolated. All C-S-G segments are identified with at least three Holocene activity, with OSL dating indicating a concentration of fault movements around 40 ka. We examined the possibility of kinematic segmentation and re-evaluated the role of these segments within the Yangsan-Ulsan fault system. Furthermore, utilizing precise mapping data, we proposed safety distances in the Gyeongju area, which can serve as fundamental data for seismic hazard assessments.

Abstract

To estimate the aseismic, co-seismic, and post-seismic displacements, we characterize the spatial pattern of ground deformation caused by the September 17 ML 6.6 Guanshan and the September 18 ML 6.8 Chihshang earthquakes in eastern Taiwan using geodetic data collected from Continuous Operating Reference Stations (CORS), corrected Single-frequency CORS (SCORS), campaign-mode GNSS/GPS survey (CMGS) stations, as well as the results from two precise leveling routes. For the ML 6.6 foreshock, our analysis from high-rate CORS data suggests ~20 cm coseismic horizontal displacements occurred between the Chihshang and Taitung area, south of the foreshock epicenter. In contrast, high-rate CORS data from the ML 6.8 Chihshang mainshock show more than 90 cm of coseismic horizontal displacements between Guanshan and Ruisui, north of the mainshock epicenter. The largest observed ground deformations roughly aligned to the western side of the Yuli fault, which is likely to be a branch of the steeply west-dipping Central Range Fault ruptured during the 2022 earthquake sequence. Altogether, the largest coseismic GPS vertical movements from the foreshock and the mainshock reach 15 cm and 85 cm on the hanging wall of the Central Range fault (i.e. Yuli Fault), and the largest observed subsidence reach 35 cm on the footwall of the Central Range Fault, and in the Coastal Range. Meanwhile, we conducted three times on CMGS and two precise leveling routes to acquire the post-seismic displacement one year after the earthquakes. The results show that post-seismic behavior is rapid along the Yuli Fault.

The characteristics of the Chihshang segment of the Longitudinal Valley Fault System, eastern Taiwan, assessed by historical aerial photo reconstructions

Tsz Yau Amundsen LAM[1]*, Department of Geosciences, National Taiwan University, Taipei (Taiwan) (r10224115@ntu.edu.tw)
J. Bruce H. Shyu[2], Department of Geosciences, National Taiwan University, Taipei (Taiwan)

Abstract

The Longitudinal Valley Fault (LVF) System is one of the most active fault systems in Taiwan. The Chihshang segment, located from Yuli to Luyeh, has been proposed as an active creeping fault and has a high slip rate of about 2-3 cm/year. However, records of historical earthquake events show that surface ruptures of the November 1951 earthquake were only observed from Yuli to Chihshang, but not between Chihshang and Luyeh in the Guanshan area. In fact, only limited studies were focused on the fault segment in the Guanshan area, partly due to the fact that human activities have significantly modified the fault trace and geomorphic features in this area. The recent development of photogrammetry techniques enabled us to use historical aerial photos to reconstruct the old landforms that may have been obliterated by human activities. Therefore, we used historical aerial photos taken from 1968 and 1969 to obtain a historical Digital Surface Model (DSM) and orthoimages using Structure from Motion (SfM) and Multi-View Stereo (MVS) methods. With the historical DSM and orthoimages, we mapped structural scarps along the fault segment in the Guanshan area. We also measured current scarp heights using Real-Time Kinematic Global Navigation Satellite System (RTK-GNSS) in the field.

Our results show that, by comparing the river terrace riser heights in the reconstructed DSM and present-day measurements, the error of the reconstructed DSM is generally much lower than 5 m. Therefore, structural scarps that are higher than 5 m can be reliably identified with reconstructed DSM using historical aerial photos. This suggests that the reconstruction of historical aerial photos can be applied to obtain previous landforms that were significantly modified by human activities and to characterize active faults in those areas.

Abstract

The Andes are classically divided according to alternating normal and flat slab subduction segments, with contrasting shortening degrees and thermal structures. This work focuses on the northernmost section of the Chilean-Pampean Flat slab (27°–33°S), above its transition to the Central Volcanic Zone (CVZ, 15°–27°S) to the north.

The Juan Fernández aseismic ridge was subducted under the trench at the Southern Puna region (in the present CVZ), during Early Miocene times, establishing a flat slab subduction setting, evidenced by the within-plate migration of the arc front.

The elbow shape of this ridge made the collision point migrate south, leading to slab steepening in Southern Puna and the onset of the Chilean-Pampean Flat slab subduction in the Late Miocene. Nowadays, the Juan Fernández ridge subducts at the southern edge of the flat slab segment (at 33°S).

Flat slabs produce arc migration, lithospheric weakening, foreland uplift at the orogenic front, and eclogitization of the subducted lower lithosphere, becoming anomalously dense and therefore, gravitationally unstable when the subducted lithosphere steepens.

Lithospheric foundering through the Southern Puna region, visualized in seismic tomographies, is spatially associated with Miocene sedimentary basins (like Arizaro, Antofalla and Pasto Ventura) and within-plate volcanic fields, re-interpreted as drip-related depocenters with alternating contractional and extensional regimes. A southward trend in their development is observable in the last 15-8 Myrs as lithospheric delamination and steepening subduction settings have been younger in this direction during Juan Fernandez's southward subduction.

Satellite imagery and fieldwork led to the recognition of contractional active deformation in the transition zone between the Andes Precordillera, a narrow fold and thrust belt that deforms Paleozoic marine and nonmarine sequences, and the western Sierras Pampeanas, the wide broken foreland associated with the Chilean-Pampean flat subduction zone (28°20´S). Three main active structural systems were analyzed: The Los Colorados thrust, the Famatina Range front fault, and

the Catinsaco-La Ciénaga fault zones. These active structural systems affect Quaternary deposits and produce changes in the drainage system showed by geomorphological and lithological evidence such as wind gaps, and ponding facies.
This out-of-sequence quaternary contractional activity is explained by the surface expression of the delamination of the Famatina Range where inverted gravity data revealed the attenuation of the lower crust, signaling this as the southernmost growing drip of the series of delaminated drips identified in the southern Puna region.

Abstract

The Miocene sedimentary basins located in the southeastern part of the Korean Peninsula record the Quaternary reactivation of intrabasinal faults. However, the Quaternary faulting has not been well studied due to its short extension and immaturity compared to large faults such as the Yangsan Fault. The aim of this study is to reveal structural and paleoseismic characteristics of the reactivated intrabasinal faults in the southern (HJ) and northern (GM) parts of the Miocene Janggi Basin and to correlate the reactivation timings of the intrabasinal faults with those in adjacent major fault zones. We conducted a detailed paleoseismic investigation, including geomorphic analysis, fieldwork, electric resistivity survey, trench excavation, and numerical age dating. Our geomorphic analysis shows two NW-SE to WNW-ESE-trending lineaments (one each in HJ and GM) that are presumed to have formed from Quaternary faulting, exhibiting vertical scarplet and linear valleys. Stratigraphic features, cross-cutting relationship, and numerical ages obtained from outcrop and excavation in the GM indicate that the most recent faulting event occurred between 229±19 and 80±2 ka, while two excavations in the HJ disclosed that the latest Quaternary faulting took place after 260±30 ka. We also observed fault-propagation folds within the Quaternary sediment layers in the HJ as well as the GM, which is indicative of the presence of blind faults activated during the Quaternary. Based on the results of comparative analysis by combining all the Quaternary faulting ages and spatiotemporal deformation patterns of the Miocene intrabainal faults and adjacent major faults, the Quaternary reactivations of the intrabasinal faults and the northern Yangsan Fault tend to exhibit incompatibility with each other. This spatiotemporal deformation pattern can provide an important key to understanding the seismic activity behavior in the intraplate region.

Abstract

At the southern Pampean flat-slab in the Central Andes, the Quaternary active deformation is concentrated on the easternmost thrusts of the Southern Precordillera along the Las Peñas-Las Higueras hill (32° 10’-32° 45’ S). This range is bounded by the Las Peñas Thrust System (LPTS), which emplaces Cenozoic sedimentary rocks over a suite of Quaternary alluvial deposits.
